The possible involvement of different effector systems (nitric oxide synthase, guanylate cyclase, \( \beta \)-adrenergic and muscarinic cholinergic receptors, cyclooxygenase and lipoxygenase, and \( \text{Na}^+,\text{K}^-\text{-ATPase} \)) was evaluated in a histamine \( \text{H}_3 \) receptor agonist-induced ((\( R \))-methylhistamine, (\( R \))-MeHA) endothelium-dependent rat aorta relaxation assay. (\( R \))-MeHA (0.1 nM - 0.01 mM) relaxed endothelium-dependent rat aorta, with a \( pD_2 \) value of 8.22 ± 0.06, compared with a \( pD_2 \) value of 7.98 ± 0.02 caused by histamine (50% and 70% relaxation, respectively). The effect of (\( R \))-MeHA (0.1 nM - 0.01 mM) was competitively antagonized by thioperamide (1, 10 and 30 nM) (\( pA_2 \) = 9.21 ± 0.40; slope = 1.03 ± 0.35) but it was unaffected by pyrilamine (100 nM), cimetidine (1 \( \mu \)M), atropine (10 \( \mu \)M), propranolol (1 \( \mu \)M), indomethacin (10 \( \mu \)M) or nordihydroguaiaretic acid (0.1 mM). Inhibitors of nitric oxide synthase, \( L^-\text{-NMMA} \), 1-\( N^-\text{H} \)-monomethylarginine (\( L^-\text{MMMA} \), 10 \( \mu \)M) and \( N^-\text{H} \)-nitro-L-arginine methyl ester (\( L^-\text{NOARG} \), 10 \( \mu \)M) inhibited the relaxation effect of (\( R \))-MeHA, by approximately 52% and 70%, respectively. This inhibitory effect of \( L^-\text{NMMA} \) was partially reversed by \( L^-\text{arginine} \) (10 \( \mu \)M). Methylene blue (10 \( \mu \)M) and ouabain (10 \( \mu \)M) inhibited relaxation (\( R \))-MeHA-induced by approximately 50% and 90%, respectively. The products of cyclooxygenase and lipoxygenase are not involved in (\( R \))-MeHA-induced endothelium-dependent rat aorta relaxation nor are the muscarinic cholinergic and \( \beta \)-adrenergic receptors. The results also suggest the involvement of NO synthase, guanylate cyclase and \( \text{Na}^+,\text{K}^-\text{-ATPase} \) in (\( R \))-MeHA-induced endothelium-dependent rat aorta relaxation.

**Introduction**

Histamine is present in essentially all tissues and it can stimulate all three classes of histamine receptors. It is found in significant concentrations in the blood and also in the vessel walls. It has been known for several years that histamine receptor subtypes vary in different isolated vascular tissues, depending upon the anatomic location, species and physiological response. It is known that two types of histamine receptors, \( \text{H}_1 \) and \( \text{H}_2 \), participate in vascular responses to histamine. Intravascular administration of histamine elicits a concentration-dependent fall in blood pressure in most species. Many studies have indicated the involvement of histamine \( \text{H}_1 \) and \( \text{H}_2 \) receptors in this depressor response. The histamine \( \text{H}_1 \) and \( \text{H}_2 \) receptor-mediated actions of histamine on effector cells are linked with the accumulation of cGMP, inositol phospholipids and cAMP, respectively. In different blood vessels cGMP formation is activated by endothelium-derived relaxing factor (EDRF) while cAMP formation is stimulated by prostacyclin (PGI2). The histamine \( \text{H}_3 \) receptors were found within the central nervous system of the rat and the human where they appear to be involved in the feedback control of both histamine synthesis and release of the level of histaminergic nerve endings. Furthermore, stimulation of histamine \( \text{H}_3 \) receptors has been shown to inhibit adrenergic and cholinergic neurotransmission in the peripheral autonomic nervous system. There is some controversy about whether histamine \( \text{H}_3 \) receptors are present on the sympathetic nerve fibres innervating blood vessels. Stimulation of histamine \( \text{H}_3 \) receptors by specific agonist mediated vascular relaxant effects is
caused by mechanism(s) which are not clear at present. In two isolated vessels, the rabbit middle cerebral artery and guinea-pig aorta a potent and selective histamine H3 agonist, \((R)\alpha\)-methylhistamine ((R)\alpha-MeHA), caused relaxation probably via stimulation of postsynaptic histamine H3 receptors. These findings suggest that, depending on the species and the experimental model, several mechanisms (activation of pre- and post-synaptic histamine H3 receptors or histamine H3 receptor-independent mechanisms) contribute to the overall effect of (R)\alpha-MeHA on cardiovascular function.\(^{17}\)

In our previous report the existence of histamine H3 receptors on rat aorta endothelium was shown.\(^ {18}\) The present study was therefore undertaken to assess the possible role of histamine H3 receptors located on the rat aorta endothelium and their interactions with other effector systems.

**Materials and Methods**

**Vascular preparations:** Male Wistar rats weighing between 100 and 200 g were stunned and the thoracic aorta was excised and dissected free of surrounding tissue. Ring segments (4 mm) were prepared and fixed isometrically in a 20 ml organ bath containing Tyrode's solution of the following composition (mM): NaCl, 136.9; KCl, 2.69; CaCl\(_2\), 1.8; MgCl\(_2\), 1.05; NaHCO\(_3\), 11.9; NaH\(_2\)PO\(_4\), 0.42; and glucose 5.55, at 37°C under a moderate tension of 1 g for 90 min (the optimal point of its length-tension curve as determined from the tension developed in response to potassium chloride 40 mM) and gassed with 95% O\(_2\)/5% CO\(_2\). The preparations were precontracted by phenylephrine (300 nM). In some preparations the endothelium was removed mechanically by gentle and careful rubbing of the intimal surface with a stainless-steel wire (31-gauge diameter) in order to avoid stretching and damaging the vascular smooth muscle cells. The presence of endothelium was confirmed by using acetylcholine (300 nM). The failure of acetylcholine to induce relaxation of preparations was taken as an indication of endothelium removal.

**Experimental procedure:** After the equilibration period, concentration-response curves were obtained by cumulative addition of histamine (0.1 nM–0.01 mM) or \((R)\alpha\)-MeHA (0.1 nM–0.01 mM) on precontracted preparations alone or in the presence of pyrilamine (100 nM), cimetidine (1 \(\mu\)M) and thioperamide (1 nM, 10 nM, 30 nM) for \((R)\alpha\)-MeHA.

All drugs were added directly to the bath in a volume of 150 \(\mu\)l and the concentrations given are the calculated final concentrations in the bath solution. When potassium chloride was used as a spasmsogen, the stated concentration excluded the potassium chloride already present in Tyrode's solution.

**Data analysis:** Responses are expressed as a percentage of the maximal relaxation induced by papaverine (100%, 0.1 mM). The slope of the log concentration–response curve, correlation coefficient \((r)\), \(E_{\text{max}}\) (maximum response) and \(pA_2\) (−log molar concentrations of antagonist reducing the agonist response by a factor of 2) values were evaluated from concentration–response curves plotted for \((R)\alpha\)-MeHA in the presence of thioperamide. For calculating these different values the data are expressed as means ± S.E.M.; \(n\) refers to the number of experiments. \(E_{\text{max}}\) values were compared using Student's \(t\)-test. \(p\) values less than 0.05 were considered to be significant.

**Drugs:** The following compounds were used: acetylcholine chloride (Sigma), phenylephrine hydrochloride (Sigma), histamine dihydrochloride (Sigma), \((R)\alpha\)-methylhistamine (Research Biochemicals Incorporated), pyrilamine maleate (Sigma), cimetidine (Sigma), thioperamide maleate (Research Biochemicals Incorporated), atropine sulphate (Sigma), propranolol hydrochloride (Sigma), L-\(N^\alpha\)-monomethylarginine (L-NMMA, Research Biochemicals Incorporated), L-arginine methyl ester hydrochloride (L-NOARG, Research Biochemicals Incorporated), L-arginine (Sigma), indomethacin (Sigma), nordihydroguaiaretic acid (NDHGA, Sigma), ouabain octahydrate (Serva), methylene blue (Sigma) and papaverin hydrochloride (Sigma). All solutions were kept on ice until use except thioperamide which was dissolved in dimethylsulphoxide (previous experiments had shown that the solvents used had no effects on the preparations) and \((R)\alpha\)-MeHA which was diluted in water and stored as an aliquot (100 \(\mu\)l) at \(-20^\circ\)C. Indomethacin was dissolved in an equimolar concentration with Na\(_2\)CO\(_3\).

**Results**

The influence of endothelium on responses to histamine and \((R)\alpha\)-MeHA: Histamine (0.1 nM–0.01 mM) induced concentration-dependent relaxation of phenylephrine (300 nM)-precontracted rat aorta with intact endothelium, reaching approximately 70% of the papaverine-induced maximum relaxation (0.1 mM) (\(pD_2 = 7.98 ± 0.02\)). Removal of the endothelium abolished the relaxation to histamine.

(R)-MeHA, log M

FIG. 1. Concentration–response curves for histamine and (R)-MeHA in rat aorta with intact endothelium ((R)-MeHA alone or in the presence of pyrilamine or cimetidine). The data are expressed as means (n=6) (S.E.M. are excluded from diagram for clarity and do not exceed 15% of the mean value for each point). ▲, (R)-MeHA; ○, histamine; ⊙, pyrilamine (100 nM); ●, cimetidine (1 μM); △, endothelium denuded.

(R)-MeHA (0.1 nM–0.01 mM) induced concentration-dependent relaxation of phenylephrine (300 nM)-precontracted rat aorta with intact endothelium reaching approximately 50% of the papaverine-induced maximum relaxation (0.1 mM) (pD₂ = 8.22 ± 0.06). Removal of the endothelium abolished the relaxation to (R)-MeHA (Fig. 1).

Effects of pyrilamine, cimetidine and thioperamide: Pyrilamine (100 nM, Kₐ for H₁ = 0.8 nM, Kₐ for H₂ = 5.2 μM, Kₐ for H₃ = > 3 μM, see Hill¹⁹) or cimetidine (1 μM, Kₐ for H₂ = 0.8 μM, Kₐ for H₁ = 0.45 nM, Kₐ for H₃ = 33 μM, see Hill¹⁹) did not influence (R)-MeHA-induced endothelium-dependent rat aorta relaxation (Fig. 1).

When thioperamide (1 nM, 10 nM, 30 nM, Kₐ for H₁ > 100 μM, Kₐ for H₂ > 10 μM, Kₐ for H₃ = 4.3 nM, see Arrang et al¹¹) was present the concentration–response curve for (R)-MeHA-induced relaxation was shifted to the right without a significant change of the Eₘₚₓ. Schild plot analysis indicated that antagonism by this compound was competitive. The slope for the regression curve was 1.03 ± 0.35 with a pA₂ value of 9.21 ± 0.40 (Fig. 2).

Effects of atropine, propranolol, indomethacin and NDHGA: Neither atropine (10 μM), propranolol (1 μM), indomethacin (10 μM) nor NDHGA (0.1 mM) significantly reduced (R)-MeHA-induced endothelium-dependent rat aorta relaxation (data not shown).

Inhibition by L-NMMA and L-NOARG: Both inhibitors of NO synthase inhibited (R)-MeHA-induced endothelium-dependent relaxation in a concentration-dependent manner and this effect was maximal after incubation with 10 μM L-NMMA or 10 μM L-NOARG (approximately 52% and 70% inhibition, respectively). The addition of L-arginine (10 μM) partly reversed L-NMMA-inhibited inhibition of the response to (R)-MeHA (Fig. 3). Higher concentrations (> 10 μM) of both inhibitors induced no further reduction of relaxation (not shown).

Inhibition by methylene blue and ouabain: Methylene blue (10 μM) inhibited the (R)-MeHA-induced endothelium-dependent rat aorta relaxation (approximately 50% inhibition). Higher concentrations (> 10 μM) of inhibitor induced no further reduction of relaxation. Ouabain (10 μM) inhibited the (R)-MeHA-induced endothelium-dependent relaxation (approximately 90% inhibition) (Fig. 4). Higher concentrations (> 10 μM) of inhibitor induced no further reduction of relaxation.
Discussion

The novel histamine H₃ receptors were identified as inhibitory presynaptic autoreceptors on histamine-containing nerve terminals in the rat brain cortex but they have since been shown to inhibit the release of various neurotransmitters both in the central and peripheral nervous system. Recent articles provide strong evidence for the presence of histamine H₃ receptors at different sites, including rabbit middle cerebral artery endothelium, guinea-pig aorta, mesenteric artery, rabbit saphenous artery, guinea-pig myocardium, guinea-pig ileum, guinea-pig lung and bronchiole, guinea-pig intestine, porcine small intestine, rabbit gastric glands, human adenoidal mast cells, and human and rhesus monkey brain. The endothelium-dependent relaxation to histamine (0.1 nM – 0.01 mM) was competitively antagonized by pyrilamine (1 nM, 7 nM, 10 nM) with a pA₂ value of 9.33 ± 0.34 and a slope of 1.09 ± 0.36. It was also competitively antagonized by thioperamide (1 nM, 10 nM, 30 nM) with a pA₂ value of 9.31 ± 0.16 and a slope of 0.94 ± 0.10, but it was unaffected by cimetidine (1 µM). The results with both histamine and pyrilamine suggest the presence of histamine H₁ receptors on rat aorta endothelium, which is in agreement with results of other authors.

Thioperamide antagonizes both histamine and (R)α-MeHA-induced relaxations resulting in about the same pA₂ values (9.31 for histamine and 9.21 for (R)α-MeHA in present paper, respectively). These pA₂ values are close to that (8.96) found for blockade of histamine H₂-mediated inhibition of [³H]-histamine release in rat brain slices. The pA₂ value of the histamine H₃ antagonist thioperamide was very similar to its values for various responses mediated by histamine H₂ receptors. A major point is the finding that histamine is more active than (R)α-MeHA, which makes it uncertain whether only histamine H₃ receptors are involved. There is a heterogeneous population of histamine receptors, H₁ and H₃, on rat aorta endothelium. This is not surprising although the known histamine vascular effects in different biological species involve two receptor systems, the histamine H₁ and histamine H₂ receptors. New observations suggest that histamine H₃ receptors are also localized at the postsynaptic level in rabbit middle cerebral artery endothelium, guinea-pig aorta, and in the epithelial wall of guinea-pig bronchioles, and act on the smooth muscle. The mechanism underlying the inhibitory effect of histamine H₃ receptor stimulation on neurotransmitter release in central and peripheral tissues remains to be established. However, comparison with other receptor systems, known to have a similar effect.
Histamine H3 receptor coupling on rat aorta endothelium

on neurotransmitter release (e.g. adenosine A1 receptor, opiate receptor and α2 adrenoceptor) suggests a number of possibilities for the effector systems linked to the histamine H3 receptor. The possibilities include inhibition of adenylate cyclase activity, activation of K⁺ channels and inhibition of voltage-dependent Ca²⁺ channels. Studies in slices of guinea-pig hippocampus have shown that the histamine H3 agonist (R)α-MeHA is not able to inhibit dimaprit-induced cAMP accumulation suggesting that histamine H3 receptors are not negatively linked to adenylate cyclase. It is known that (R)α-MeHA, a potent and selective histamine H3 agonist, induced endothelium-dependent relaxation of high-K⁺ precontracted rabbit middle cerebral artery. That relaxation was not affected by β-adrenoceptors, muscarinic or dopamine receptor antagonists. Our results with atropine and propranolol also showed that neither muscarinic cholinergic receptors nor β-adrenoceptors were involved in (R)α-MeHA-induced endothelium-dependent rat aorta relaxation.

The identification of nitric oxide (NO) (or a compound containing the NO ligand) such as EDRF and the finding that L-NMMA or L-NOARG are inhibitors of NO synthesis in vascular endothelium have emphasized the importance of local control of vasomotor tone. Nitric oxide enhances production of cGMP in vascular smooth muscles through activation of soluble guanylate cyclase, which in turn activates Ca²⁺-ATPase to reduce intracellular Ca²⁺ concentration and induces muscle relaxation. It has been demonstrated that L-NAME (a competitive inhibitor of NO synthesis), specifically inhibits cGMP formation due to the activation of muscarinic, histamine, bradykinin and neurotensin receptors in mouse neuroblastoma N1E-115 cells. In our experiments the inhibitory effects of L-NMMA and L-NOARG on (R)α-MeHA-induced endothelium-dependent rat aorta relaxation were also observed, indicating that these substances inhibit NO formation by competing with L-arginine for binding to NO synthase. The addition of L-arginine partly reversed L-NMMA-induced inhibition of response. We also found that the inhibitory effect of L-NOARG was greater than that of L-NMMA (70% and 52%, respectively) which is in agreement with the observations of different authors. Methylene blue (which blocks guanylate cyclase) prevented the increase in cGMP and thus inhibited (R)α-MeHA-induced endothelium-dependent rat aorta relaxation.

The decrease with age in the dilator response of rat thoracic aorta to histamine is due to a decreased cGMP production and to an age-dependent decrease in endothelium function. Also, in guinea-pig airway smooth muscle histamine can activate nitric oxide synthase resulting in the release of NO.

In different blood vessels, cGMP formation is activated by EDRF while cAMP formation is stimulated by PGI₂. Particularly from experiments with endothelial cells cultured in vitro several classes of agonist have been demonstrated to interact with surface receptors leading to PGI₂ synthesis. These include proteins and peptides (thrombin and bradykinin), amines (histamine at H3 receptors), eicosanoids (leukotriene C4) and purines (ATP and ADP). (R)α-MeHA-induced endothelium-dependent rabbit middle cerebral artery relaxation was partially reduced by tranylcypromine (an inhibitor of leukotriene synthesis) and also inhibited by dexamethasone (an inhibitor of prostaglandin synthesis probably at the level of phospholipase A2 and indomethacin (an inhibitor of PGI₂ synthesis) indicated that a prostanoid (probably PGI₂) could also be involved in (R)α-MeHA-induced endothelium-dependent rabbit middle cerebral artery relaxation. The implication of results with indomethacin and NDHGA is that (R)α-MeHA does not induce the release of the relaxing factors containing metabolites of arachidonic acid via cyclooxygenase (e.g. PGE₁, PGE₂, PGI₂) or via lipoxygenase (leukotrienes) on rat aorta endothelium.

In many arteries, the release of EDRF by acetylcholine (Ach) is accompanied by an endothelium-dependent hyperpolarization, while EDHF is the possible mediator. The EDHF-induced hyperpolarization is produced by an increased permeability of the membrane to K⁺ ions with no change in either cAMP or cGMP. It has also been concluded that the hyperpolarization resulted from stimulation of Na⁺,K⁺-ATPase. It has been observed that in rat aorta and rat main pulmonary artery Ach released two different substances from endothelium. On factor (EDRF) is responsible for vascular muscle relaxation while the other (EDHF) hyperpolarizes the muscle membrane by opening K⁺ channels. However, ouabain (an inhibitor of the Na⁺,K⁺-ATPase) inhibited (R)α-MeHA-induced endothelium-dependent rat aorta relaxation much more than L-NOARG (90% and 70% inhibition, respectively). It means that in addition to NO, some factor other than NO (e.g. EDHF) could participate in (R)α-MeHA-induced endothelium-dependent rat aorta relaxation. Inhibition of the Na⁺,K⁺-ATPase by ouabain would shift the membrane potential to a less negative level and thus reduce or abolish any hyperpolarization associated with K⁺ channel opening.

In conclusion, we suggest that the products of
ATPase in histamine H3 receptor agonist-induced NO synthase, guanylate cyclase and Na\(^+\),K\(^+\) muscarinic cholinergic and \([\beta\)-adrenergic receptors. The results also suggest the involvement of NO synthase, guanylate cyclase and Na\(^+\),K\(^+\)-ATPase in histamine H3 receptor agonist-induced (\([\alpha\beta\) MEA-H3) endothelium-dependent rat aorta relaxation.
