DISCRETE COMPARISON PRINCIPLES FOR QUASILINEAR ELLIPTIC PDE

SARA POLLOCK AND YUNRONG ZHU

Abstract. Comparison principles are developed for discrete quasilinear elliptic par-
tial differential equations. We consider the analysis of a class of nonmonotone Leray-
Lions problems featuring both nonlinear solution and gradient dependence in the prin-
cipal coefficient, and a solution dependent lower-order term. Sufficient local and global
conditions on the discretization are found for piecewise linear finite element solutions
to satisfy a comparison principle, which implies uniqueness of the solution. For prob-
lems without a lower-order term, our analysis shows the meshsize is only required to be
locally controlled, based on the variance of the computed solution over each element.
We include a discussion of the simpler semilinear case where a linear algebra argument
allows a sharper mesh condition for the lower order term.

1. Introduction

We consider the finite element approximation of the quasilinear elliptic partial differ-
etial equation (PDE)

$$-
\text{div}(a(x, u, \nabla u)) + b(x, u) = 0 \text{ in } \Omega \subset \mathbb{R}^d,$$

(1.1)

where $a(x, \eta, \xi) = A(x, \eta, \xi)\xi$, for scalar-valued $A : \Omega \times \mathbb{R} \times \mathbb{R}^d \to \mathbb{R}$, and $b : \Omega \times \mathbb{R} \to \mathbb{R}$. The domain $\Omega$ is assumed to be piecewise polygonal for $d = 2$, or an interval for $d = 1$. The boundary $\partial \Omega$ is decomposed into Dirichlet and Neumann parts, where the Dirichlet part $\Gamma_D \subseteq \partial \Omega$ has positive measure in $\mathbb{R}^{d-1}$, and the Neumann part is
given by $\Gamma_N = \partial \Omega \setminus \Gamma_D$. The boundary conditions applied to (1.1) are either mixed
Dirichlet/Neumann or homogeneous Dirichlet, given by

$$u = 0 \text{ on } \Gamma_D, \text{ and } a(x, u, \nabla u) \cdot n(x) = \psi(x) \text{ on } \Gamma_N,$$

(1.2)

for outward facing normal $n$. The aim of this paper is to extend the discrete comparison
principle and uniqueness results recently obtained by the authors to a more general class
of quasilinear elliptic equations.

Significant progress has been made on developing discrete maximum principles for
divergence form quasilinear elliptic problems, as in [11, 17, 18, 19, 27], and develop-
ing the appropriate conditions on the angles of the mesh for these results to hold. In
the nonlinear context, comparison principles rather than maximum principles for a given
equation imply the uniqueness of solutions. Comparison principles also provide impor-
tant information such as a natural ordering of solutions that can be useful in the analysis
of numerical solutions. There are still only few results on discrete comparison principles
for problem (1.1), despite the significant literature on corresponding results for continu-
ous problems, e.g., [3, 4, 12, 16, 24], and [14, Chapter 10], and the references therein.

To our knowledge, the first comparison theorem and global uniqueness result for a discrete version of problems in this class that holds as the mesh is refined, is that of [2], for the equation \(-\text{div}(\kappa(x,u)\nabla u) = f(x)\), where both a uniformly small meshsize and an acuteness condition on the angles of the mesh were used. Uniqueness of solutions for simplicial and rectangular elements of arbitrary order with numerical quadrature was later established in [1] for this class of problems, dependent on a uniformly small meshsize. The meshsize assumption for \(P_1\) elements was relaxed in a comparison theorem framework in recent work by the current authors in [22], where the global meshsize condition was replaced by a local condition on the maximum variance of the solution over each element, locally limiting the meshsize where the solution has steep gradients.

The main contributions of the current manuscript are that we now allow a more general diffusion coefficient, including a nonlinear dependence on the gradient; and, a (nonlinear) solution-dependent lower order term. These results allow the determination of whether the solution to a finite element approximation of (1.1) is unique, based only on knowledge of problem data, and accessible properties of the computed solution and the mesh. This information is useful in the analysis of adaptive algorithms (e.g., [20, 21]), and can be used to verify the uniqueness of a discrete solution upon numerical convergence. Importantly, these results hold globally, as opposed to locally, within the neighborhood of a given solution; and, without \text{a priori} knowledge of the solution to (1.1).

1.1. Problem class. The following assumptions on the diffusion coefficient, by means of the function \(a_i(x,\eta,\xi) = A(x,\eta,\xi)\xi_i\), \(i = 1, \ldots, d\), for \(x \in \Omega, \eta \in \mathbb{R}\), and \(\xi \in \mathbb{R}^d\), are made throughout the remainder of the paper.

**Assumption 1.1.** Assume \(a(x,\eta,\xi)\) and \(b(x,\eta)\) are Carathéodory functions, \(C^1\) in \((\eta, \xi)\) (respectively, \(\eta\)) for almost every (a.e.) \(x \in \Omega, \eta \in \mathbb{R}\), and measurable in \(x\) for each \((\eta, \xi) \in \mathbb{R} \times \mathbb{R}^d\) (respectively, for each \(\eta \in \mathbb{R}\)). Assume \(a\) is elliptic in the following sense. There is a positive constant \(\gamma_a\) with

\[
\sum_{i=1}^d \frac{\partial a_i}{\partial \xi_j}(x,\eta,\xi)\zeta_i\zeta_j \geq \gamma_a|\zeta|^2.
\]

for a.e. \(x \in \Omega\), and for all \(\eta \in \mathbb{R}\), \(\xi \in \mathbb{R}^d\) and \(\zeta \in \mathbb{R}^d\). There is a constant \(K_\eta > 0\) with

\[
\left|\frac{\partial A}{\partial \eta}(x,\eta,\xi)\right| \leq K_\eta,
\]

for a.e. \(x \in \Omega\) and for all \(\eta \in \mathbb{R}\) and \(\xi \in \mathbb{R}^d\). Assume \(b\) is nondecreasing in \(\eta\), and there is a constant \(B_\eta \geq 0\) with

\[
0 \leq \frac{\partial b}{\partial \eta}(x,\eta) \leq B_\eta,
\]

for a.e. \(x \in \Omega\) and \(\eta \in \mathbb{R}\).

The conditions of Assumption 1.1, used here to show a comparison theorem and uniqueness of the discrete solution, also satisfy the hypotheses of Theorem 10.7 of [14], under condition (ii), which shows a comparison theorem for the continuous problem.

**Remark 1.2** (Existence of solutions). To understand existence of the PDE solution, it is useful to consider the Leray-Lions and coercivity conditions (see for example [8, Chapter 2]). In addition to the Carathéodory assumption above, the following conditions assure the pseudo-monotonicity of the principal part of the elliptic operator.
(1) Growth condition: there is a function \( k_0(x) \in L^q(\Omega) \) and \( c_0 > 0 \) with
\[
|A(x, \eta, \xi)\xi_i| \leq k_0(x) + c_0(|\eta|^{p-1} + |\xi|^{p-1}), \quad i = 1, \ldots, d,
\]
with \( 1 < p < \infty \) and \( 1/p + 1/q = 1 \).

(2) Monotonicity with respect to \( \xi \): the coefficients \( a_i = A\xi_i \) satisfy
\[
\sum_{i=1}^{d} (A(x, \eta, \xi)\xi_i - A(x, \eta, \bar{\xi})\bar{\xi_i})(\xi_i - \bar{\xi_i}) > 0,
\]
for a.e. \( x \in \Omega \), all \( \eta \in \mathbb{R} \), and for all \( \xi, \bar{\xi} \in \mathbb{R}^d \) with \( \xi \neq \bar{\xi} \).

(3) Coercivity: there is a constant \( \nu > 0 \) and a function \( k(x) \in L^1(\Omega) \) with
\[
\sum_{i=1}^{d} A(x, \eta, \xi)\xi_i^2 \geq \nu|\xi|^p - k(x),
\]
for a.e. \( x \in \Omega \), all \( \eta \in \mathbb{R} \) and all \( \xi \in \mathbb{R}^d \).

Classes of problems satisfying the above conditions are well-studied in the literature with respect to existence of solutions and their boundedness properties. For instance, existence of solutions is shown in Chapter II.6 of [23], under the strengthened coercivity condition and additional growth condition on the lower order term
\[
\sum_{i=1}^{d} A(x, \eta, \xi)\xi_i^2 \geq c_r|\xi|^p - K_r(K(x) + |\eta|^r)
\]
\[
b(\eta) \leq K_r(k_0(x) + |\eta|^r),
\]
for \( k_0(x) \) from condition (1) above, some \( 1 \leq r < p \) and \( K(x) \in L^1(\Omega) \) (see [23] Lemma 6.4).

Cases where both Assumptions [1,4] and conditions (1)-(3) above are satisfied are not uncommon. First, if in addition to Assumption [1,4] there are constants \( 0 < \lambda_A \leq \Lambda_A \) with \( \lambda_A \leq A(x, \eta, \xi) \leq \Lambda_A \), then conditions (1)-(3) hold with \( p = q = 2 \). This includes the case where \( a_i(x, \eta, \xi) = A(x, \eta, \xi)\xi_i \), as in the earlier investigation [22], with \( b \equiv 0 \), which features applications to nonlinear heat conduction, for example [16]. More generally, these conditions hold if \( A(x, \eta, \xi) \) has the form \( A(x, \eta, \xi) = A_0(x, \eta) + A_1(x, \eta)f(|\xi|) + A_2(x)g(|\xi|) \), where \( A_0 \) is bounded away from zero, and \( f(|\xi|) \) and \( g(|\xi|) \) satisfy appropriate growth conditions. Problems of this form will be specifically considered in the discrete two dimensional case.

The discrete equations for monotone instances of the above classes, those in which the principal coefficient is independent of \( \eta \), such as the \( p \)-Laplacian, are analyzed in for instance [5, 6, 11], and under stronger monotonicity and Lipschitz assumptions in [9, 13], exploiting the variational structure of the problem to establish uniqueness without a comparison principle. A more general approximation strategy using a Hybrid High-Order method is presented in [10]. In that setting, strong convergence of the sequence of discrete solutions is found as the meshsize goes to zero for monotone problems, but the result holds only up to a subsequence if \( a(x, \eta, \xi) \) maintains its \( \eta \)-dependence, i.e., for nonmonotone problems (see [10] Theorem 4.6). The emphasis of this article is establishing verifiable sufficient conditions for the uniqueness of the discrete solution for the case where \( a(x, \eta, \xi) \) of [1,1] maintains its \( \eta \)-dependence, and is not then monotone (or variational, see [16]), but rather pseudo-monotone, as described above.

The weak form of (1.1) is given by integration against test functions \( v \) which lie in an appropriate subspace \( V_{0,D} \subset V \subseteq H^1 \cap W^{1,p} \), where \( V_{0,D} = \{ v \in V \mid v = 0 \text{ on } \Gamma_D \} \),
and $p$ is determined by the particular problem class, as in Remark 1.2. The reader is referred to [8, §3.2] for detailed discussion on the existence and comparison results for the continuous Dirichlet problem. Then, the weak form of the problem is: find $u \in V_{0,D}$ such that

$$
\int_{\Omega} a(x, u, \nabla u) \cdot \nabla v + b(x, u) v \, dx = \int_{\Gamma_N} \psi(x) v \, ds, \quad \text{for all } v \in V_{0,D},
$$

(1.6)

where the Neumann data $\psi(x)$ is assumed to be bounded and measurable. For the remainder of the paper, we proceed with conditions of Assumptions 1.1, and investigate the conditions under which a discrete comparison principle holds, assuming the existence of a discrete subsolution and supersolution, as defined in the next section.

The remainder of the article is structured as follows. In §2 we state the discretization, and introduce the framework for proving the discrete comparison principle. In §3 this framework is applied to the simple case of the one dimensional problem. Then, in §4 the two dimensional problem is considered. First, additional restrictions on the discretization (angle conditions) are introduced. Then, in §4.1 useful estimates for the technical lemmas of §4.3 are reviewed. The main 2D result, Theorem 4.9, follows in §4.4. In §5 we prove a comparison principle for a simpler semilinear problem based on the previous estimates. In Theorem 5.3 we then apply a linear algebraic approach to improve the mesh condition.

2. OVERVIEW OF COMPARISON FRAMEWORK

We next overview the discretization and the comparison theorem framework. The subsequent sections contain the precise results and technical proofs. The cases of one and two dimensions are worked out separately to give explicit constants that can be used as criteria for verifying uniqueness of a discrete solution on a given mesh.

2.1. Discretization. Let $\mathcal{T}$ be a conforming partition of domain $\Omega$ that exactly captures the boundary of $\Omega$, and each of $\Gamma_D$ and $\Gamma_N$. In one dimension, $\mathcal{T}$ is a collection of intervals, and in two dimensions a triangulation. Let $\mathcal{D}$ be the collection of vertices or nodes of $\mathcal{T}$, and let $\mathcal{D} = \overline{\mathcal{D}} \setminus \Gamma_D$. The nodes $a \in \mathcal{D}$ correspond to the mesh degrees of freedom. Let $\mathcal{V} := V_{0,D} \subset V_{0,D}$ be the discrete space spanned by the piecewise linear basis functions $\{\varphi_j\}$ that satisfy $\varphi_i(a_j) = \delta_{ij}$ for each $a_j \in \mathcal{D}$.

For simplicity of defining the finite element solution space, the discussion assumes a homogeneous Dirichlet part under either the mixed or pure Dirichlet conditions. The method of the proof trivially generalizes to allow nonhomogeneous bounded measurable Dirichlet data, as its contribution is subtracted off as is the Neumann data, on the first step.

2.2. Discrete comparison framework. The discrete Galerkin problem for $\mathcal{V}$ is: find $u \in \mathcal{V}$ such that

$$
\int_{\Omega} a(x, u, \nabla u) \cdot \nabla v + b(x, u) v \, dx = \int_{\Gamma_N} \psi(x) v \, ds, \quad \text{for all } v \in \mathcal{V}.
$$

(2.1)

A subsolution to (2.1) is a function $u_1 \in \mathcal{V}$ with

$$
\int_{\Omega} a(x, u_1, \nabla u_1) \cdot \nabla v + b(x, u_1) v \, dx - \int_{\Gamma_N} \psi(x) v \, ds \leq 0,
$$

(2.2)
for all \( v \in \mathcal{V}^+ = \{ v \in \mathcal{V} \mid v \geq 0 \} \). A corresponding supersolution \( u_2 \in \mathcal{V} \) is given by

\[
\int_{\Omega} a(x, u_2, \nabla u_2) \cdot \nabla v + b(x, u_2)v\,dx - \int_{\Gamma_N} \psi(x)v\,ds \geq 0, \quad \text{for all } v \in \mathcal{V}^+. \tag{2.3}
\]

Subtracting (2.3) from (2.2), we find

\[
\int_{\Omega} (a(x, u_1, \nabla u_1) - a(x, u_2, \nabla u_2)) \cdot \nabla v + (b(x, u_1)v - b(x, u_2)v)\,dx \leq 0, \tag{2.4}
\]

for all \( v \in \mathcal{V}^+ \). Decomposing the principal part by \( a(x, u, \nabla u) = A(x, u, \nabla u) \nabla u \), and applying Taylor’s theorem, it holds for \( w = u_1 - u_2 \) that

\[
(a(x, u_1, \nabla u_1) - a(x, u_1, \nabla u_2)) + (A(x, u_1, \nabla u_2) - A(x, u_2, \nabla u_2)) \nabla u_2
\]

\[
= \int_0^1 \frac{\partial a}{\partial \xi}(x, u_1, \nabla z(t)) \nabla w\,dt + \int_0^1 \frac{\partial A}{\partial \eta}(x, z(t), \nabla u_2)w\nabla u_2\,dt, \tag{2.5}
\]

for \( z(t) = tu_1 + (1 - t)u_2 \). Similarly for the lower order term

\[
b(x, u_1) - b(x, u_2) = \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t))w\,dt. \tag{2.6}
\]

Applying (2.5) and (2.6) to (2.4), and breaking the integral over the global domain into a sum of integrals over each element \( T \in \mathcal{T} \), obtain

\[
\int_{\Omega} \int_0^1 \left( \frac{\partial a}{\partial \xi}(x, u_1, \nabla z(t)) \nabla w\right) \cdot \nabla v + \left( \frac{\partial A}{\partial \eta}(x, z(t), \nabla u_2)w \right) \nabla u_2 \cdot \nabla v
\]

\[
+ \frac{\partial b}{\partial \eta}(x, z(t))wv\,dt\,dx
\]

\[
= \sum_{T \in \mathcal{T}} \int_T \int_0^1 \left( \frac{\partial a}{\partial \xi}(x, u_1, \nabla z(t)) \nabla w\right) \cdot \nabla v + \left( \frac{\partial A}{\partial \eta}(x, z(t), \nabla u_2)w \right) \nabla u_2 \cdot \nabla v
\]

\[
+ \frac{\partial b}{\partial \eta}(x, z(t))wv\,dt\,dx \leq 0, \tag{2.7}
\]

for all \( v \in \mathcal{V}^+ \). The structure of \( a(x, u, \nabla u) = A(x, u, \nabla u) \nabla u \) is exploited in the first term of the above decomposition to yield a quantity that is strictly positive, and in the second term to create a quantity controlled by the difference in nodal values of \( u_2 \). This factorization is a key component of the problem class that allows a condition for uniqueness similar to that in [22], dependent on the variance of the discrete solution \( u \) over each element.

The proof of the comparison principle follows by considering a particular test function \( v \in \mathcal{V}^+ \), and finding under Assumption 1.1 and additional assumptions on the discretization, that if \( w > 0 \) anywhere, the left hand side integration over elements of (2.7) is strictly positive, yielding a contradiction and implying \( w \leq 0 \) everywhere, hence \( u_1 \leq u_2 \) in \( \Omega \). Common test functions for this purpose in the continuous context include the positive part of \( w = u_1 - u_2 \), possibly taken to some power, as in [34]. In the discrete setting, the positive part of \( w \) is generally not a member of the finite element space, so a discrete version of this function can be used, as in [27]. In this case, as in [22], it is convenient to define a simpler test function \( v \) as follows.

**Definition 2.1.** Let \( u_1 \in \mathcal{V} \) be a subsolution of (2.1) as in (2.2), and let \( u_2 \in \mathcal{V} \) be a supersolution as in (2.3). Let \( w = u_1 - u_2 \in \mathcal{V} \). Define the test function \( v \in \mathcal{V}^+ \subset \mathcal{V} \) by
its nodal values at each \( a \in \mathcal{D} \) as

\[
v(a) = \begin{cases} 
1, & w(a) > 0, \\
0, & w(a) \leq 0. 
\end{cases} \quad (2.8)
\]

If \( w > 0 \) anywhere on \( \Omega \), then \( v(a) \) is nonzero for some \( a \in \mathcal{D} \). One of the convenient properties of this test function \( v \), is that \( \nabla v = 0 \) over each \( T \in \mathcal{T} \) where \( w \) does not change sign. In fact, for the 1D case, an even simpler test function can be defined for which \( v' \) is supported over no more than two elements. This strategy was used in \([22]\); however, in this presentation we will use the same Definition (2.1) for both one and two dimensions to unify the arguments.

Partition the sets \( \mathcal{T}_+, \mathcal{T}_- \) and \( \mathcal{T}_c \) by the value of \( v \) from Definition (2.1) restricted to each element in \( \mathcal{T} \).

\[
\mathcal{T}_+ = \{ T \in \mathcal{T} \mid v(x)_{|T} \equiv 1 \}, \quad \mathcal{T}_- = \{ T \in \mathcal{T} \mid v(x)_{|T} \equiv 0 \}, \quad \mathcal{T}_c = \mathcal{T} \setminus \{ \mathcal{T}_+ \cup \mathcal{T}_- \}. \tag{2.9}
\]

Write the integral over \( \Omega \) as

\[
\int_{\Omega} = \int_{\bigcup_{T \in \mathcal{T}_+}} + \int_{\bigcup_{T \in \mathcal{T}_-}} + \int_{\bigcup_{T \in \mathcal{T}_c}}.
\]

Each integral over \( T \in \mathcal{T}_- \) is trivially zero. Each integral over \( T \in \mathcal{T}_+ \) satisfies \( \nabla v \equiv 0 \), and the remaining lower order part is nonnegative by

\[
\int_{T \in \mathcal{T}_c} \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t)) w v \, dt \, dx = \int_{T \in \mathcal{T}_c} \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t)) w \, dt \, dx \geq 0, \tag{2.10}
\]

as \( w > 0 \), \( v = 1 \) and \( \partial b/\partial \eta \geq 0 \), by (1.5) of Assumption (1.1). It remains then to bound the integrals over \( T \in \mathcal{T}_c \) where \( w \) changes sign. In summary, we have from (2.4), (2.7) and (2.10) that

\[
0 \geq \int_{\Omega} (a(x, u_1, \nabla u_1) - a(x, u_2, \nabla u_2)) \cdot \nabla v + (b(x, u_1)v - b(x, u_2))v \, dx \\
\geq \sum_{T \in \mathcal{T}_c} \int_T \int_0^1 \left( \frac{\partial a}{\partial x}(x, u_1, \nabla z(t)) \right) \cdot \nabla v + \frac{\partial A}{\partial \eta}(x, z(t), \nabla u_2)w \nabla u_2 \cdot \nabla v \\
+ \frac{\partial b}{\partial \eta}(x, z(t)) w v \, dt \, dx, \tag{2.11}
\]

for \( v \) given by Definition (2.1). We next develop conditions on the discretization in one and two dimensions for which the above inequality cannot hold.

3. RESULTS FOR ONE DIMENSION

Let \( \Omega = (\alpha, \beta) \), with a subdivision

\[
\alpha = a_0 < a_1 < \ldots < a_{n-1} < a_n = \beta, \tag{3.1}
\]

where the mesh spacing is not assumed to be uniform. Define the intervals \( \mathcal{I}_k = (a_{k-1}, a_k), k = 1, \ldots, n \), and let \( \Delta_k = a_k - a_{k-1} \), the length of each respective interval. Then \( \mathcal{T} = \bigcup_{1 \leq k \leq n} (\mathcal{I}_k) \). Let \( v' = dv/dx \). In one dimension, for the mixed problem with Dirichlet conditions at \( x = \beta \), with Neumann data \( \psi(\alpha) \in \mathbb{R} \), the weak form (1.6) reduces to: find \( u \in \mathcal{V} := \mathcal{V}_{0,\beta} \) such that

\[
\int_{\Omega} a(x, u, u')v' + b(x, u)v \, dx = \psi(\alpha)v(\alpha) \quad \text{for all } v \in \mathcal{V}. \tag{3.2}
\]
For the pure Dirichlet problem, (1.6) reduces to: find $u \in \mathcal{V} := \mathcal{V}_0$ such that
\[
\int_{\Omega} a(x, u, u')v' + b(x, u)v \, dx = 0, \quad \text{for all } v \in \mathcal{V}. \tag{3.3}
\]
Without confusion, the discrete space $\mathcal{V}$ refers to either $\mathcal{V}_{0, \beta}$, containing the piecewise linear functions that vanish at $x = \beta$ for problem (3.2); or, $\mathcal{V}_0$, containing functions that vanish at $x = \alpha$ and $x = \beta$ for problem (3.3).

**Theorem 3.1** (One dimensional comparison theorem). Let $u_1$ be a subsolution as in (2.2) of either the mixed problem (3.2) or the Dirichlet problem (3.3); and, let $u_2$ be a supersolution as in (2.3), of the same problem. Assume the conditions of Assumption 1.1 and
\[
\max_{1 \leq k \leq n} \left\{ |u_2(a_k) - u_2(a_{k-1})| + \left( \frac{B_\eta}{K_\eta} \right) h_k^2 \right\} < \frac{2\gamma_0}{K_\eta}. \tag{3.4}
\]
Then, it holds that $u_1 \leq u_2$ in $\Omega$.

If the lower order term $b$ is independent of $u$, then $B_\eta = 0$, and the condition (3.4) is similar to that in (2.2), for a more general diffusion coefficient. If, on the other hand, $B_\eta > 0$, global mesh condition is introduced, as $h_k < \sqrt{2\gamma_0/B_\eta}$ for all $k = 1, \ldots, n$, is a necessary condition for satisfaction of (3.4).

The proof of Theorem 3.1 follows by using the test function $v$ from Definition 2.1 to show the right-hand side of (2.11) is strictly positive.

**Proof.** Assume $w = u_1 - u_2$, is positive somewhere in $\Omega$. Then $\mathcal{T}_c$ is nonempty, and in one dimension, inequality (2.11) reduces to
\[
0 \geq \sum_{I_k \in \mathcal{T}_c} \int_{I_k} \int_0^1 \frac{\partial a}{\partial \xi}(x, u_1, z(t))w'v' + \frac{\partial A}{\partial \eta}(x, z(t), u')wv' + \frac{\partial b}{\partial \eta}(x, z(t))wv \, dt \, dx. \tag{3.5}
\]
Proceed by bounding each term on the right-hand side of (3.5). On each interval $I_k \in \mathcal{T}_c$, $w$ changes sign, and by Definition 2.1 the functions $w'$ and $v'$ are constants with the same sign. Then, the product $w'v' = |w(a_k) - w(a_{k-1})|/h_k^2$ on $I_k$, and it holds that
\[
\int_{I_k} \int_0^1 \frac{\partial a}{\partial \xi}(x, u_1, z)w'v' \, dt \, dx = \frac{|w(a_k) - w(a_{k-1})|}{h_k^2} \int_{I_k} \int_0^1 \frac{\partial a}{\partial \xi}(x, u_1, z) \, dt \, dx \geq \frac{|w(a_k) - w(a_{k-1})|}{h_k} \gamma_a, \tag{3.6}
\]
where $\gamma_a$ is the constant from (1.3). For the second term of (3.5), it is useful to note that $\int_{I_k} |w| \leq |w(a_k) - w(a_{k-1})|h_k/2$, as precisely one of $w(a_k)$ and $w(a_{k-1})$ must be positive. Then
\[
\int_{I_k} \int_0^1 \frac{\partial A}{\partial \eta}(x, z(t), u')wv' \, dt \, dx \geq \frac{-K_\eta|u_2(a_k) - u_2(a_{k-1})|}{h_k^2} \int_{I_k} |w| \, dx \geq -\left( \frac{|w(a_k) - w(a_{k-1})|}{h_k} \right) K_\eta \frac{|u_2(a_k) - u_2(a_{k-1})|}{2}; \tag{3.7}
\]
where $K_\eta$ is the constant from (1.4). Each integral over last term of (3.5) satisfies
\[
\int_{I_k} \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t))wv \, dt \, dx \geq -B_\eta \int_{I_k} |w| \, dx \geq -|w(a_k) - w(a_{k-1})| \frac{B_\eta h_k}{2}. \tag{3.8}
\]
where $B_\eta$ is the constant from (1.5). Putting (3.6), (3.7) and (3.8) together into (3.5) yields

$$0 \geq \sum_{I_k \in T_c} \left\{ |w(a_k) - w(a_{k-1})|/h_k \left( \gamma_a - |u_2(a_k) - u_2(a_{k-1})|/2 + \frac{K_\eta}{2} - h_k^2 B_\eta^2/2 \right) \right\} > 0,$$

where the strict positivity in the last inequality holds under the condition (3.4). This contradiction establishes that $w = u_1 - u_2$ cannot be positive anywhere on $\Omega$. □

As any solution $u$ to (3.2) or (3.3) is both a subsolution and a supersolution, the uniqueness of solutions follows, under the assumption

$$\max_{1 \leq k \leq n} \left\{ |u(a_k) - u(a_{k-1})|/|T| \right\} + \left( \frac{B_\eta}{K_\eta} h_k^2 \right) < \frac{2 \gamma_a}{K_\eta}. \quad (3.9)$$

The constants $\gamma_a$, $B_\eta$ and $K_\eta$ are based purely on the problem data, and if they are known or can be approximated for a given problem, then (3.9) can be easily and efficiently checked, and used to determine uniqueness of a given computed solution. It is important in particular for adaptive algorithms to have such a condition which assures the uniqueness of the discrete solution without unavailable a priori knowledge. As demonstrated by the counterexamples of [2] (cf. [22]), some conditions on the discretization are indeed necessary to assure the uniqueness of the solution.

4. RESULTS FOR TWO DIMENSIONS

We next establish the uniqueness of the piecewise linear finite element solution to (2.1) in two dimensions, under Assumption (1.1). The simplicial mesh is assumed to be uniformly acute, and the smallest angle to be bounded away from zero.

**Assumption 4.1 (Mesh regularity).** There are numbers $0 < t_{\min} \leq t_{\max} < \pi/2$, for which the interior angles $\theta_i$, $i = 1, 2, 3$, of each $T \in T$ satisfy

$$t_{\min} \leq \theta_i \leq t_{\max}, \quad i = 1, 2, 3. \quad (4.1)$$

Define the quantities

$$s_{\min} = \sin(t_{\min}), \quad \text{and} \quad c_{\min} = \cos(t_{\max}). \quad (4.2)$$

The acuteness condition which states that angles are bounded below $\pi/2$, agrees with that in [22] for the simpler case of $a(x, \eta, \xi) = A(x, \eta)\xi$. In the following analysis, the condition that the angles are bounded away from zero is used to control the maximum ratio of edge-lengths in any triangle.

The relation between the measure of each element $T$, and the lengths of the sides are given by standard trigonometric descriptions. For each $T \in T$, let $|T|$ denote the two-dimensional measure, or area. For any two distinct edges $e_i$ and $e_j$, the area $|T| = |e_i||e_j|\sin\theta_{ij}/2$, for $\theta_{ij}$ the interior angle between edges $e_i$ and $e_j$. This provides the useful formula $|e_i||e_j|/|T| = 2/\sin\theta_{ij}$. Under Assumption 4.1 the ratio of the sines of any pair of angles in a triangle $T$ is bounded away from zero. Define the local constants

$$c_T := \min_{i,j=1,2,3} \cos\theta_i, \quad (4.3)$$

$$s_T := \max_{i,j=1,2,3} \sin\theta_i, \quad (4.4)$$

$$r_T := \min_{i,j=1,2,3} \sin\theta_i/\sin\theta_j, \quad \text{for} \quad \theta_i, \quad i = 1, 2, 3, \quad \text{the angles of} \ T. \quad (4.5)$$
The constant $r_T$ is used to relate the lengths of edges of triangle $T$ by

$$r_T |e_i| \leq |e_j| \leq r_T^{-1} |e_i|, \ i, j = 1, 2, 3. \quad (4.6)$$

Each vertex corresponding to a mesh degree of freedom, $a \in D$, has coordinates $a = (x_1, x_2) \in \bar{\Omega} \setminus \Gamma_D$. From (2.1) $V := V_{0,D}$ is the piecewise linear Lagrange finite element space subordinate to partition $T$, that vanishes on $\Gamma_D$ in the sense of the trace.

4.1. Relations between gradients of basis functions. To clarify the technical lemmas that follow, some standard notations and properties of piecewise linear finite elements in two dimensions are now reviewed. The following relations involving gradients of basis functions are used often in the analysis.

Let $\{a_1, a_2, a_3\}$ be a local counterclockwise numbering of the vertices of a simplex $T \in \mathcal{T}$. Let the corresponding edges $\{e_1, e_2, e_3\}$, follow a consistent local numbering, with edge $e_i$ opposite vertex $a_i$, $i = 1, 2, 3$. Let $\varphi_i$ be the basis function on element $T \in \mathcal{T}$ defined by its nodal values at the vertices of $T$.

$$\varphi_i(a_j) = \begin{cases} 1, & i = j, \\ 0, & i \neq j. \end{cases}, \ i, j = 1, 2, 3.$$

The inner product between gradients of basis functions and their respective integrals over elements $T \in \mathcal{T}$, may be computed by change of variables to a reference element $\hat{T}$, in reference domain variables $(\hat{x}_1, \hat{x}_2)$. Specifically, the coordinates of $\hat{T}$ are given as $\hat{a}_1 = (0, 0)^T$, $\hat{a}_2 = (1, 0)^T$, $\hat{a}_3 = (0, 1)^T$. The Jacobian of the transformation between reference coordinates $\hat{x} = (\hat{x}_1, \hat{x}_2)^T$, and physical coordinates $x = (x_1, x_2)^T$, is given by $J\hat{x} = |x - a_1|$, with $J = (a_2 - a_1 \ a_3 - a_1)^T$, for which $\det J = 2 |T|$, with $|T|$ the area of triangle $T$. The reference element $\hat{T}$ is equipped with the nodal basis functions $\hat{\varphi}_i$, $i = 1, 2, 3$, where $\hat{\varphi}_1 = 1 - \hat{x}_1 - \hat{x}_2$, $\hat{\varphi}_2 = \hat{x}_1$, $\hat{\varphi}_3 = \hat{x}_2$. The gradients $\nabla$ are taken with respect to the reference domain variables $\hat{x}_1$ and $\hat{x}_2$, and the transformation of gradients between the physical and reference domains is given by $\nabla \varphi_i = J^{-T} \hat{\nabla} \hat{\varphi}_i$. The gradients of basis functions satisfy the identity

$$\nabla \varphi_i + \nabla \varphi_j = -\nabla \varphi_k, \quad (4.7)$$

for any distinct assignment of $i, j$ and $k$ to the integers $\{1, 2, 3\}$. This allows the representation of $\nabla \varphi_i^T \nabla \varphi_i$ in terms of edge-length $|e_i|$. The maximum interior angle $\theta_{\max} < \pi/2$ from Assumption 4.1 then assures $\nabla \varphi_i^T \nabla \varphi_j < 0$, for any $i \neq j$. The inner products between gradients in each element $T$ satisfy the following identities:

$$\nabla \varphi_i^T \nabla \varphi_i = \frac{1}{4 |T|^2} |e_i|^2, \quad \text{and} \quad \nabla \varphi_i^T \nabla \varphi_j = -\frac{1}{4 |T|^2} |e_i||e_j| \cos \theta_k, \ i \neq j. \quad (4.8)$$

4.2. Additional assumptions for the 2D problem. We next establish estimates which demonstrate for any $T \in \mathcal{T}_c$, given by (2.9), that

$$\int_{\mathcal{T}} \int_0^1 \left( \frac{\partial a}{\partial \xi} (x, u_1, \nabla z(t)) \nabla w \right) \cdot \nabla v + \left( \frac{\partial A}{\partial \eta} (x, z(t), \nabla u_2) w \right) \nabla u_2 \cdot \nabla v + \frac{\partial b}{\partial \eta} (x, z(t)) w v \, dt \, dx > 0, \quad (4.9)$$

with $v$ the test function given by Definition 2.1. In light of (2.11), this establishes by contradiction that $w = u_1 - u_2$ is nowhere positive. To bound the leading term of (4.9) away from zero, some additional restrictions on the nonlinear diffusion coefficient $A$ are now considered.
Assumption 4.2. Assume \( A(x, \eta, \xi) \) is of the form
\[
A(x, \eta, \xi) = A_0(x, \eta) + A_1(x, \eta) f(|\xi|) + A_2(x) g(|\xi|). \tag{4.10}
\]
Assume there is a positive constant \( \lambda_0 \), and there are nonnegative \( \Lambda_1 \) and \( \Lambda_2 \), with
\[
A_0(x, \eta) \geq \lambda_0, \quad 0 \leq A_1(x, \eta) \leq \Lambda_1, \quad \text{and} \quad 0 \leq A_2(x) \leq \Lambda_2, \tag{4.11}
\]
for a.e. \( x \in \Omega \), and all \( \eta \in \mathbb{R} \), and \( \xi \in \mathbb{R}^2 \).

Assume \( f(s), g(s) \geq 0 \), and \( f \) satisfies the following growth condition. There is a constant \( C_f \) with
\[
s|f'(s)| \leq C_f, \quad \text{for all } s \geq 0. \tag{4.12}
\]
Assume \( g \) satisfies one of the two following conditions.
\[
s|g'(s)| \leq C_g, \quad \text{for all } s \geq 0, \tag{4.13}
\]
\[
s|g'(s)| \leq \tilde{C}_g g(s), \quad \text{for all } s \geq 0, \quad \text{with} \quad 0 \leq \tilde{C}_g \leq c_{\min}. \tag{4.14}
\]

The function \( g \) is not assumed to be either bounded or bounded away from zero, while the boundedness of \( f \) is required from (1.4) of Assumption 1.1. Functions \( f \) and \( g \) that satisfy Assumption 4.2 are not uncommon. Some examples are given in the next remark.

Remark 4.3. Admissible functions \( \phi(|\xi|) \) that satisfy (4.12), (4.13) include the following.
\[
\phi(|\xi|) = (\kappa + |\xi|^2)^{-\alpha}, \quad \text{for } \kappa > 0 \quad \text{and} \quad \alpha \geq 0,
\]
which appears for instance as the diffusion coefficient in the equation for capillarity (see [14, Chapter 10] ) as well as the equations of prescribed mean curvature (see [26]), with \( \kappa = 1 \) and \( \alpha = 1/2 \).
\[
\phi(|\xi|) = 2 \left( K_0 + \sqrt{K_0^2 + 4|\xi|} \right)^{-1}, \quad K_0 > 0,
\]
which is numerically investigated as a specific explicit case of the more general implicitly defined coefficient used in the modeling of glacier ice, as analyzed in [15].
\[
\phi(|\xi|) = \arctan(|\xi|), \quad \text{and} \quad \phi(|\xi|) = \tanh(|\xi|).
\]
Unbounded functions that satisfy (4.13) include
\[
\phi(|\xi|) = \log(\kappa + |\xi|^2), \quad \kappa > 1,
\]
which allows for \( g(|\xi|) \) hence \( A(x, \eta, \xi) \) to be unbounded, albeit with slow growth.

Functions satisfying (4.14) include those of \( p \text{-Laplacian type}, \) for \( p \) close to 2.
\[
\phi(|\xi|) = |\xi|^{p-2}, \quad \text{for } |p-2| < c_{\min}.
\]

4.3. Technical lemmas in two dimensions. An important quantity in the analysis is the maximum variance of a function over a given element. For piecewise linear functions, this is simply the maximum difference between any two vertex values on a given triangle.

Definition 4.4. For a function \( \phi \in \mathcal{V} \), and element \( T \in \mathcal{T} \), define \( \delta_T(\phi) \) as follows.
\[
\delta_T(\phi) = \max_{i,j=\{1,2,3\}} |\phi(a_i) - \phi(a_j)|, \tag{4.15}
\]
where \( \{a_1, a_2, a_3\} \), are the vertices of \( T \).
In the technical lemmas which bound each term in the expansion \((4.9)\), the following identity is used repeatedly.

\[
\nabla \phi = \phi(a_i) \nabla \varphi_i + \phi(a_j) \nabla \varphi_j + \phi(a_k) \nabla \varphi_k \\
= \phi(a_i) \nabla \varphi_i + \phi(a_j) \nabla (\varphi_j + \varphi_k) + (\phi(a_k) - \phi(a_j)) \nabla \varphi_k \\
= (\phi(a_i) - \phi(a_j)) \nabla \varphi_i + (\phi(a_k) - \phi(a_j)) \nabla \varphi_k.
\]  

(4.16)

The first Lemma characterizes the strict positivity of the first term of \((4.9)\).

**Lemma 4.5.** Let Assumptions 1.1, 4.1 and 4.2 hold, with \(g\) satisfying \((4.13)\). Let \(w, u \in \mathcal{V}\), and \(z(t) \in \mathcal{V}, 0 \leq t \leq 1\). Let \(a_i, a_j\) and \(a_k\) be the three vertices of \(T \in \mathcal{T}_c\), ordered so that \(w(a_i) \geq w(a_j) \geq w(a_k)\) with \(w(a_i) > 0\) and \(w(a_k) \leq 0\). Let \(v\) be given by Definition 2.7. Assume there is a constant \(p_T > 0\), for which the constants \(\lambda_0, \Lambda_1\) and \(\Lambda_2\) of \((4.11)\), and \(C_f\) and \(C_g\) of \((4.12)\) and \((4.13)\), satisfy the relation

\[
p_T := \lambda_0 \cos \theta_j - \Lambda_1 C_f - \Lambda_2 C_g > 0.
\]  

(4.17)

1. If \(w(a_j) \leq 0\), namely \(w\) is positive only at the vertex \(a_i\), it holds that

\[
\int_T \int_0^1 \nabla w^T \left( \frac{\partial a}{\partial \xi}(x, u, \nabla z(t)) \right)^T \nabla v \ dt \ dx \\
\geq \frac{1}{2 \sin \theta_j} \left\{ (w(a_i) - w(a_j)) \frac{\gamma_a}{r_T} + (w(a_j) - w(a_k)) p_T \right\}.
\]  

(4.18)

2. If \(w(a_j) \geq 0\), namely \(w\) is positive at both \(a_i\) and \(a_j\), it holds that

\[
\int_T \int_0^1 \nabla w^T \left( \frac{\partial a}{\partial \xi}(x, u, \nabla z(t)) \right)^T \nabla v \ dt \ dx \\
\geq \frac{1}{2 \sin \theta_j} \left\{ (w(a_i) - w(a_j)) p_T + (w(a_j) - w(a_k)) \frac{\gamma_a}{r_T} \right\}.
\]  

(4.19)

**Proof.** First, expand \(\nabla w\) as a linear combination of basis functions as in \((4.16)\). For any \(\nabla z \in \mathbb{R}^2\), abbreviating \(\partial a(x, u, \nabla z)/\partial \xi\) as \((\partial a/\partial \xi)\), and noting the structure of \(a\) implies the symmetry of \(\partial a/\partial \xi\), we have

\[
\nabla w^T \left( \frac{\partial a}{\partial \xi} \right)^T \nabla v = (w(a_i) - w(a_j)) \nabla \varphi_i^T \left( \frac{\partial a}{\partial \xi} \right) \nabla v \\
+ (w(a_k) - w(a_j)) \nabla \varphi_k^T \left( \frac{\partial a}{\partial \xi} \right) \nabla v.
\]  

(4.20)

In the case that \(w\) has one positive vertex, \(\nabla v = \nabla \varphi_i\), and in the case that \(w\) has two positive vertices, \(\nabla v = -\nabla \varphi_k\). In the first case, the ellipticity condition \((1.3)\) implies

\[
(w(a_i) - w(a_j)) \nabla \varphi_i^T \left( \frac{\partial a}{\partial \xi} \right) \nabla v \\
\geq (w(a_i) - w(a_j)) \frac{\gamma_a}{r_T} \frac{|e_i|}{4|T|^2} \\
= (w(a_i) - w(a_j)) \frac{\gamma_a}{r_T} \frac{1}{2|T| \sin \theta_j},
\]  

(4.21)
where $r_T$ defined in (4.5) is used to relate the lengths of edges $e_i$ and $e_k$. In the second case, the same condition implies

$$\begin{align*}
(w(a_k) - w(a_j))\nabla \varphi^T_k \left( \frac{\partial a}{\partial \xi} \right) \nabla v &\geq (w(a_j) - w(a_k)) \gamma_a \nabla \varphi^T_k \nabla \varphi_k \\
&\geq (w(a_j) - w(a_k)) \frac{\gamma_a}{r_T} \frac{1}{2 |T| \sin \theta_j}. \quad (4.22)
\end{align*}$$

The above estimate for each case yields a strictly positive contribution. For the remaining term of (4.20), apply the decomposition of Assumption 4.2

$$\begin{align*}
\nabla \varphi^T_i \left( \frac{\partial a}{\partial \xi} \right) \nabla \varphi_k &= \nabla \varphi^T_i \nabla z \left( \frac{\partial A}{\partial \xi} \right) \nabla \varphi_k + A(x, u, \nabla z) \nabla \varphi^T_i \nabla \varphi_k \\
&= (\nabla \varphi'^T_i \nabla z) \left\{ A_1(x, u) \frac{\partial f}{\partial \xi} (|\nabla z|) + A_2(x) \frac{\partial g}{\partial \xi} (|\nabla z|) \right\} \nabla \varphi_k \\
&\quad + A(x, u, \nabla z) \nabla \varphi^T_i \nabla \varphi_k.
\end{align*}$$

The Jacobian of $f(|\xi|)$ (respectively, $g(|\xi|)$) has the form

$$\frac{\partial f}{\partial \xi} (|\xi|) = f'(|\xi|)|\xi|^{-1} \xi^T.$$ 

The first term on the right-hand side of (4.23) then satisfies

$$\begin{align*}
(\nabla \varphi'^T_i \nabla z) A_1(x, u) \frac{\partial f}{\partial \xi} (|\nabla z|) \nabla \varphi_k &\leq A_1 (|\nabla \varphi'^T_i \nabla z|) |f'(|\nabla z|)||\nabla \varphi_k| \\
&\leq A_1 |\nabla \varphi_i|||\nabla \varphi_k||f'(|\nabla z|)||\nabla z| \\
&\leq A_1 C_f |\nabla \varphi_i|||\nabla \varphi_k|.
\end{align*}$$

where the last inequality follows from (4.12). Similarly for the second term on the right-hand side of (4.23), it holds

$$\begin{align*}
(\nabla \varphi'^T_i \nabla z) A_2(x) \frac{\partial g}{\partial \xi} (|\nabla z|) \nabla \varphi_k &\leq A_2 C_g |\nabla \varphi_i|||\nabla \varphi_k|. \quad (4.25)
\end{align*}$$

With the Assumption 4.2, it is clear that $A(x, u, \nabla z) \geq \lambda_0$. Therefore the third term on the right-hand side of (4.23) satisfies

$$\begin{align*}
A(x, u, \nabla z) \nabla \varphi'^T_i \nabla \varphi_k &= -A(x, u, \nabla z) \frac{|e_i||e_k| \cos \theta_j}{4|T|^2} \\
&\leq -\lambda_0 \frac{|e_i||e_k| \cos \theta_j}{4|T|^2}. \quad (4.26)
\end{align*}$$

Applying (4.24), (4.25) and (4.26) to (4.23), we obtain

$$\begin{align*}
-\nabla \varphi'^T_i \left( \frac{\partial a}{\partial \xi} \right) \nabla \varphi_k &\geq \frac{|e_i||e_k|}{4|T|^2} (\lambda_0 \cos \theta_j - \Lambda_1 C_f - \Lambda_2 C_g) = \frac{p_T}{2|T| \sin \theta_j}, \quad (4.27)
\end{align*}$$

where the sign on the left-hand side agrees with $(w(a_k) - w(a_j))$ in the case of one positive vertex where $\nabla v = \nabla \varphi_i$; and $-(w(a_j) - w(a_k))$, in the case of two positive vertices, where $\nabla v = -\nabla \varphi_k$. For the case of one positive vertex, putting (4.20) together with (4.21) and (4.27) and integrating, yields

$$\int_T \int_0^1 \nabla w^T \left( \frac{\partial a}{\partial \xi} \right) \nabla v \, dt \, dx \geq \frac{1}{2 \sin \theta_j} \left\{ (w(a_i) - w(a_j)) \frac{\gamma_a}{r_T} + (w(a_j) - w(a_k)) p_T \right\},$$

establishing (4.18). The inequality (4.19) follows similarly, replacing (4.21) with (4.22). \(\square\)
The next corollary shows the corresponding result if the condition on $g$, (4.13), is replaced by (4.14), in Assumption 4.2.

**Corollary 4.6.** Let Assumptions 1.1, 4.1 and 4.2 hold, with $g$ satisfying (4.14). Let $w, u \in V$, and $z(t) \in V$, $0 \leq t \leq 1$. Let $a_i$, $a_j$ and $a_k$ be the three vertices of $T \in T_c$, ordered so that $w(a_i) \geq w(a_j) \geq w(a_k)$ with $w(a_i) > 0$ and $w(a_k) \leq 0$. Let $v$ be given by Definition 2.7. Assume there is a constant $p_T > 0$, for which the constants $\lambda_0$ and $\Lambda_1$ of (4.11), and $C_f$ of (4.12), satisfy the relation

$$p_T := \lambda_0 \cos \theta_j - \Lambda_1 C_f > 0.$$  

(1) If $w(a_j) \leq 0$, namely $w$ is positive only at the vertex $a_i$, it holds that

$$\int_T \int_0^1 \nabla w^T \left( \frac{\partial a}{\partial \xi}(x, u, \nabla z(t)) \right)^T \nabla v \, dt \, dx \geq \frac{1}{2 \sin \theta_j} \left\{ (w(a_i) - w(a_j)) \lambda_0 \frac{r_T}{r_T} + (w(a_j) - w(a_k)) p_T \right\}. \quad (4.30)$$

(2) If $w(a_j) \geq 0$, namely $w$ is positive at both $a_i$ and $a_j$, it holds that

$$\int_T \int_0^1 \nabla w^T \left( \frac{\partial a}{\partial \xi}(x, u, \nabla z(t)) \right)^T \nabla v \, dt \, dx \geq \frac{1}{2 \sin \theta_j} \left\{ (w(a_i) - w(a_j)) p_T + (w(a_j) - w(a_k)) \lambda_0 \frac{r_T}{r_T} \right\}. \quad (4.31)$$

The proof is similar to Lemma 4.5 and the differences are summarized below.

**Proof.** The estimates (4.20)-(4.24) remain unchanged, and (4.25) is replaced by

$$(\nabla \varphi_i^T \nabla z) A_2(x) \frac{\partial g}{\partial \xi}(|\nabla z|) \nabla \varphi_k \leq A_2(x) g'(|\nabla z|) \nabla \varphi_i^T \nabla z \nabla z^T \nabla \varphi_k |\nabla z|^{-1} \leq A_2(x) g'(|\nabla z|) |\nabla z| \nabla \varphi_i^T \left( \frac{\nabla z \nabla z^T}{\nabla z^T \nabla z} \right) \nabla \varphi_k \leq A_2(x) \tilde{C}_g g(|\nabla z|) \frac{|e_i||e_k|}{4|T|^2}. \quad (4.32)$$

The bound (4.26) is now replaced by

$$A(x, u, \nabla z) \nabla \varphi_i^T \nabla \varphi_k = -A(x, u, \nabla z) \frac{|e_i||e_k| \cos \theta_j}{4|T|^2} \leq -(\lambda_0 + A_2(x)g(|\nabla z|)) \frac{|e_i||e_k| \cos \theta_j}{4|T|^2}. \quad (4.33)$$

Using (4.32) and (4.33) in place of (4.25) and (4.26), in (4.27) yields

$$-\nabla \varphi_i^T \left( \frac{\partial a}{\partial \xi} \right) \nabla \varphi_k \geq \frac{|e_i||e_k|}{4|T|^2} \left( \lambda_0 \cos \theta_j - \Lambda_1 C_f + A_2(x) g(|\xi|) (\cos \theta_j - \tilde{C}_g) \right) \geq \frac{|e_i||e_k|}{4|T|^2} \left( \lambda_0 \cos \theta_j - \Lambda_1 C_f \right) = \frac{p_T}{2|T| \sin \theta_j}, \quad (4.34)$$

under assumption (4.14). The remainder of the proof remains unchanged. □

The second term of (4.9) is bounded by the estimates of Lemma 4.7. These are similar to the ones found in [22], where a Lipschitz assumption replaces the bound on the derivative $\partial A/\partial \eta$. The key idea is to write $|w|$ as a multiple of $\delta_T(w) = w(a_i) - w(a_k)$, which can then be factored out of each term in the expansion (4.9). The positive part is given
by the results of Lemma 4.5 and the parts that may not be positive are controlled by the variance in the coefficients of $u_2$, which functions as a measurable control as found in Lemma 4.7 and, by the meshsize in the lower order term as given in Lemma 4.8.

**Lemma 4.7.** Let Assumptions $\{1.1, 4.1\}$ hold. Let $w, u \in \mathcal{V}$, and $z(t) \in \mathcal{V}$, $0 \leq t \leq 1$. Let $a_i, a_j$ and $a_k$ be the three vertices of $T \in \mathcal{T}_c$, ordered so that $w(a_i) \geq w(a_j) \geq w(a_k)$ with $w(a_i) > 0$ and $w(a_k) \leq 0$. Let $v$ be given by Definition 2.7. Then, it holds that

$$\int_{T} \int_{0}^{1} \frac{\partial A}{\partial \eta}(x, z(t), \nabla u)w \nabla u^T \nabla v \, dt \, dx \geq \frac{-\delta_T(w)\delta_T(u)}{2\sin \theta_j} \frac{7K_\eta}{6} (1 + r_T^{-1}).$$  

**Proof.** In the case that $w$ has one positive vertex, $\nabla v = \nabla \varphi_i$. Applying expansion (4.16) to $\nabla u$, followed by (4.5), one finds

$$\nabla u^T \nabla v = (u(a_i) - u(a_j)) \nabla \varphi_i^T \nabla \varphi_i + (u(a_k) - u(a_j)) \nabla \varphi_k^T \nabla \varphi_i$$

$$\leq \delta_T(u) \frac{|e_i| |e_k|}{4|T|^2} (1 + r_T^{-1})$$

$$= \frac{\delta_T(u)}{2|T| \sin \theta_j} (1 + r_T^{-1}).$$  

In the case that $w$ has two positive vertices, $\nabla v = -\nabla \varphi_k$, leading to the same result.

$$\nabla u^T \nabla v = -(u(a_i) - u(a_j)) \nabla \varphi_i^T \nabla \varphi_i - (u(a_k) - u(a_j)) \nabla \varphi_k^T \nabla \varphi_k$$

$$\leq \frac{\delta_T(u)}{2|T| \sin \theta_j} (1 + r_T^{-1}).$$  

Applying the bound (1.4) on $(\partial A/\partial \eta)$, then yields

$$\int_{T} \int_{0}^{1} \frac{\partial A}{\partial \eta}(x, z(t), \nabla u)w \nabla u^T \nabla v \, dt \, dx \leq \frac{K_\eta \delta_T(u)}{2|T| \sin \theta_j} (1 + r_T^{-1}) \int_{T} |w| \, dx. \tag{4.38}$$

As shown in [22], and repeated here for convenience, the integral over $T$ of $|w|$, can be bounded in terms of $\delta_T(w)$ making use of $\varphi_i + \varphi_j + \varphi_k = 1$, and the ordering $w(a_i) \geq w(a_j) \geq w(a_k)$.

$$|w| = |w(a_i)\varphi_i + w(a_j)\varphi_j + w(a_k)\varphi_k|$$

$$= |(w(a_i) - w(a_j))\varphi_i + (w(a_k) - w(a_j))\varphi_k + w(a_j)(\varphi_i + \varphi_j + \varphi_k)|$$

$$\leq (w(a_i) - w(a_j))\varphi_i + (w(a_j) - w(a_k))\varphi_k + (w(a_j) - w(a_k))$$

$$= (w(a_i) - w(a_j))\varphi_i + (w(a_j) - w(a_k))(1 + \varphi_k).$$

Applying $\int_{T} \varphi_i \, dx = \int_{T} \varphi_k \, dx = |T|/6$, demonstrates

$$\int_{T} |w| \, dx \leq (w(a_i) - w(a_j)) \frac{|T|}{6} + (w(a_j) - w(a_k)) \frac{7|T|}{6} \leq \delta_T(w) \frac{7|T|}{6}. \tag{4.39}$$

Putting together (4.38) and (4.39), yields the desired result. 

Finally, we consider a bound on the third term of (4.9).

**Lemma 4.8.** Let Assumptions $\{1.1, 4.1\}$ hold. Let $w, u \in \mathcal{V}$, and $z(t) \in \mathcal{V}$, $0 \leq t \leq 1$. Let $a_i, a_j$ and $a_k$ be the three vertices of $T \in \mathcal{T}_c$, ordered so that $w(a_i) \geq w(a_j) \geq w(a_k)$. Suppose $w(a_k) \leq 0$. Let $v$ be given by Definition 2.7. Then, it holds that

$$\int_{T} \int_{0}^{1} \frac{\partial b}{\partial \eta}(x, z(t))wv \, dx \, dt \geq -\delta_T(w) \frac{7B_\eta |T|}{6}. \tag{4.40}$$
Proof. Applying the condition (1.5) bounding \((\partial b/\partial \eta)\), and (4.39) bounded \(|w|\), reveals
\[
\int_T \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t))wv \, dx \, dt \geq -B_\eta \int_T |w| \, dx \geq -\delta_T(w)\frac{7B_\eta|T|}{6}.
\]

Notably, (4.40) can be controlled by the area \(|T|\) in the numerator, rather than \(\delta_T(u)\) as in the result of Lemma 4.7. Effectively, this introduces a global meshsize condition as in the 1D case if the lower order term \(b(x, u)\) appears in (1.1).

4.4. Comparison theorem in two dimensions. We are now ready to combine the results of Lemmas 4.5, 4.7 and 4.8 to prove a discrete comparison theorem.

**Theorem 4.9** (Two dimensional comparison theorem). Let \(u_1 \in \mathcal{V}\) be a subsolution of (2.1) as in (2.2), and let \(u_2 \in \mathcal{V}\) be a supersolution of the same problem, as in (2.3). Let \(w = u_1 - u_2 \in \mathcal{V}\). Let Assumptions I.1, 4.1 and 4.2 hold, with \(g\) satisfying (4.13). Assume \(\lambda_0, \Lambda_1, \Lambda_2\) and \(C_f, C_g\) of Assumption 4.2, and \(c_{\min}\) of (4.2) satisfy the relation
\[
\lambda_0c_{\min} - \Lambda_1C_f - \Lambda_2C_g > 0. \tag{4.41}
\]

Define the positive constant for each \(T \in \mathcal{T}\)
\[
p_T^* := \min\{\lambda_0c_T - \Lambda_1C_f - \Lambda_2C_g, \gamma_a/r_T\}, \tag{4.42}
\]
with \(\gamma_a\) from (1.1), \(c_T\) from (4.3) and \(r_T\) from (4.6). Then, the satisfaction of the condition
\[
\min_{T \in \mathcal{T}} \left\{ p_T^* - \delta_T(u_2)\frac{7K\eta(1 + r_T^{-1})}{6} - \frac{7B_\eta|T|s_T}{3} \right\} > 0, \tag{4.43}
\]
with \(s_T\) from (4.4), implies that \(u_1 \leq u_2\) in \(\Omega\).

Proof. Assume \(w = u_1 - u_2\) is positive somewhere in \(\Omega\). This implies \(w(a) > 0\) for some vertex \(a \in \mathcal{D}\). Let the test function \(v \in \mathcal{V}^+\) be given by Definition 2.1. Then, from (2.11), it holds that
\[
\sum_{T \in \mathcal{T}_c} \int_T \int_0^1 \left( \frac{\partial a}{\partial \xi}(x, u_1, \nabla z(t)) \nabla w \right) \cdot \nabla v + \left( \frac{\partial A}{\partial \eta}(x, z(t), \nabla u_2) w \right) \nabla u_2 \cdot \nabla v
\]
\[+ \frac{\partial b}{\partial \eta}(x, z(t))wv \, dt \, dx \leq 0, \tag{4.44}
\]
where \(\mathcal{T}_c\) defined in (2.9) is the set of all elements \(T\) where \(w\) is positive on either one or two vertices. The hypothesis (4.41) together with Lemma 4.5 implies for any \(T \in \mathcal{T}_c\), it holds that
\[
\int_T \int_0^1 \left( \frac{\partial a}{\partial \xi}(x, u_1, \nabla z(t)) \nabla w \right) \cdot \nabla v \, dt \, dx \geq \frac{\delta_T(w)}{2 \sin \theta_{T,j}} p_T^*, \tag{4.45}
\]
where \(\theta_{T,j}\) refers to \(\theta_j\) of triangle \(T\) with respect to the local indexing, where \(a_i, a_j\) and \(a_k\) are the three vertices of \(T\), ordered so that \(w(a_i) \geq w(a_j) \geq w(a_k)\).

Lemma 4.8, together with the inequality \(\sin \theta_j \leq s_T\), where \(s_T\) is the sine of the maximum angle of \(T\) as in (4.4), shows for any \(T \in \mathcal{T}_c\) that
\[
\int_T \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t))wv \, dt \, dx \geq - \left( \frac{\delta_T(w)}{2 \sin \theta_{T,j}} \right) \frac{7B_\eta|T|s_T}{3}. \tag{4.46}
\]
Putting (4.45) and (4.46) and the result of Lemma 4.7 together into (2.11) yields
\[\int_{\Omega} (a(x, u_1, \nabla u_1) - a(x, u_2, \nabla u_2)) \cdot \nabla v + (b(x, u_1)v - b(x, u_2)v) \, dx \]
\[\geq \sum_{T \in \mathcal{T}_c} \frac{\delta_T(v)}{2 \sin \theta_{T,j}} \left\{ p^*_T - \delta_T(u_2) \frac{7K_\eta(1 + r^{-1}_T)}{6} - \frac{7B_\eta |T| s_T}{3} \right\} > 0. \tag{4.47} \]
The positivity of (4.47) is in direct contradiction to the nonpositivity from (4.44), repeated from (2.11). This demonstrates that under the hypotheses of the theorem, the function \(v\) must be nowhere positive, which requires \(u_1 \leq u_2\) in \(\Omega\). \(\square\)

Replacing Lemmas 4.5 with Corollary 4.6 and 4.8 allows us to prove a second comparison result.

**Corollary 4.10.** Let \(u_1 \in \mathcal{V}\) be a subsolution of (2.1) as in (2.2), and let \(u_2 \in \mathcal{V}\) be a supersolution of the same problem, as in (2.3). Let \(w = u_1 - u_2 \in \mathcal{V}\). Let Assumptions 1.1, 4.1, and 4.2 hold, with \(g\) satisfying (4.14). Assume \(\lambda_0, \Lambda_1\) and \(C_f\) of Assumption 4.2 and \(c_{\min}\) of (4.2) satisfy the relation
\[\lambda_0 c_{\min} - \Lambda_1 > 0.\]
Define the positive constant for each \(T \in \mathcal{T}\)
\[p^*_T := \min\{\lambda_0 c_T - \Lambda_1 C_f, \gamma_a / r_T\}, \tag{4.48}\]
with \(\gamma_a\) from (4.1), \(c_T\) from (4.3), and \(r_T\) from (4.6). Then, the satisfaction of the condition
\[\min_{T \in \mathcal{T}} \left\{ p^*_T - \delta_T(u_2) \frac{7K_\eta(1 + r^{-1}_T)}{6} - \frac{7B_\eta |T| s_T}{3} \right\} > 0, \]
with \(s_T\) from (4.4), implies that \(u_1 \leq u_2\) in \(\Omega\).

**Proof.** The proof follows directly by replacing Lemma 4.5 by Corollary 4.6 in (4.45) of the proof of Theorem 4.9. \(\square\)

**Remark 4.11** (Uniqueness of finite element solutions). An important consequence of the comparison theorem is the uniqueness of solutions to (2.1), which as demonstrated holds in two dimensions under the hypotheses of Theorem 4.9 under the condition
\[\min_{T \in \mathcal{T}} \left\{ p^*_T - \delta_T(u) \frac{7K_\eta(1 + r^{-1}_T)}{6} - \frac{7B_\eta |T| s_T}{3} \right\} > 0, \]
with \(p^*_T\) given either by (4.42) or (4.48). The quantities involved to verify this condition consist of global constants bounding the problem data and local quantities characterizing the triangulation and the computed solution \(u\). The global constants are \(\lambda_0, \Lambda_1, \Lambda_2\) and \(C_f, C_g\) or \(\tilde{C}_g\) of Assumption 4.2 and \(\gamma_a, K_\eta, B_\eta\) of Assumption 1.1. The necessary triangulation data describes the area \(|T|\) and the smallest and largest angles of each element \(T \in \mathcal{T}\): \(c_T, r_T\) and \(s_T\) of (4.3)–(4.5). Finally, it is required to check the greatest difference between nodal values of the computed solution on each element, \(\delta_T(u)\). All these quantities can be easily and efficiently computed in practice.

Notably, the global meshsize condition comes only from the lower order term, and solutions to the pure diffusion problem can be demonstrated unique without a globally small meshsize. Essentially, the meshsize needs to be small where the gradient is large.
5. A SEMILINEAR PROBLEM

In this section, we consider the discrete comparison principle for a special case of the problem class (1.1), the semilinear problem:

$$-\Delta u + b(x, u) = 0 \quad \text{in} \quad \Omega \subset \mathbb{R}^d, \quad u = 0 \quad \text{on} \quad \partial \Omega. \tag{5.1}$$

For simplicity, we consider the homogeneous Dirichlet problem in one and two dimensions. The nonlinearity $b(x, u)$ is assumed to satisfy the requirements of Assumption 1.1. The discrete version of problem (5.1) is: Find $u \in \mathcal{V}$ such that

$$\int_{\Omega} \nabla u^T \nabla v + b(x, u)v \, dx = 0, \quad \text{for all} \quad v \in \mathcal{V}. \tag{5.2}$$

Based on the previous sections, we can obtain the following discrete comparison result for (5.2), which is a simplified version of Theorem 3.1 and Theorem 4.9 in the semilinear case. However, we find this technique leads to a suboptimal mesh condition. We improve the condition with a linear algebra argument in Theorem 5.3. While the techniques of Theorem 5.3 do not apply to the quasilinear problem (1.1), they suggest sharper criteria for comparison theorems and uniqueness may be attainable. We include both approaches for the semilinear problem (5.1) for completeness.

**Theorem 5.1.** Let $u_1 \in \mathcal{V}$ be a subsolution of (5.2), and let $u_2 \in \mathcal{V}$ be a supersolution of (5.2). Let $w = u_1 - u_2 \in \mathcal{V}$. Let $b(x, u)$ satisfy the Assumption 1.1 and for the 2D problem, let the partition satisfy Assumption 1.1. Under the respective conditions for the 1D and 2D problems:

$$h_k^2 < \frac{2}{B_q}, \quad k = 1, 2, \ldots, n, \quad \text{for} \quad d = 1, \tag{5.3}$$

$$|T| < \frac{3}{7B_q} \min_{k=1,2,3} \cot \theta_{T,k}, \quad \text{for each} \quad T \in \mathcal{T}, \quad \text{for} \quad d = 2, \tag{5.4}$$

it holds that $u_1 \leq u_2$ in $\Omega$.

**Proof.** We proceed by contradiction. Assume $w = u_1 - u_2$ is positive on at least one vertex of $\mathcal{T}$. Then $w$ changes signs on each $T \in \mathcal{T}_c$, which must be nonempty. Let $v$ be defined as in Definition 2.1.

In the 1D case, similar to Theorem 3.1 on each $I_k \in \mathcal{T}_c$, the product $w'v' = |w(a_k) - w(a_{k-1})|/h_k^2$. Thus by condition (5.3) we have

$$\int_{I_k} w'v' + (b(x, u_1) - b(x, u_2))v \, dx \geq |w(a_k) - w(a_{k-1})| \left( \frac{1}{h_k} - \frac{B_q h_k}{2} \right) > 0.$$

This contradicts the condition that $u_1$ and $u_2$ are sub- and supersolutions of (5.2).

In the 2D case, on each $T \in \mathcal{T}_c$, label the vertices $a_i$, $a_j$ and $a_k$ such that $w(a_i) \geq w(a_j) \geq w(a_k)$. Then with the Assumption 4.1 it holds for the case $w(a_j) \leq 0$, that

$$\int_T \nabla w \nabla v \, dx = (w(a_i) - w(a_j)) \int_T \nabla \varphi_i^T \nabla \varphi_i \, dx + (w(a_k) - w(a_j)) \int_T \nabla \varphi_k^T \nabla \varphi_i \, dx$$

$$= \frac{1}{2} (w(a_i) - w(a_j)) (\cot \theta_i + \cot \theta_j) + \frac{1}{2} (w(a_j) - w(a_k)) \cot \theta_j$$

$$\geq \frac{1}{2} (w(a_i) - w(a_k)) \cot \theta_j$$

$$= \frac{1}{2} \delta_T(w) \cot \theta_j.$$
As in Lemma 4.5, the case \( w(a_j) > 0 \) follows similarly. By Lemma 4.8 and (5.4), we have
\[
\int_T \nabla w \nabla v \, dx + \int_T (b(x, u_1) - b(x, u_2)) v \, dx \geq \frac{1}{2} \delta_T(w) \left( \cot \theta_j - \frac{7B_n|T|}{3} \right) > 0.
\]
Under (5.4) this yields a contradiction, establishing the result. \( \square \)

A more direct linear algebraic approach to determine a discrete comparison principle which implies the uniqueness of (5.2) is next demonstrated. We can derive the discrete comparison principle by considering a discrete maximum principle for the difference \( w = u_1 - u_2 \), where \( u_1 \in V \) is a subsolution of (5.2), and \( u_2 \in V \) is a supersolution of (5.2). Similarly to (2.7), the piecewise linear equation would induce a nonsymmetric matrix.

Let \( n_{dof} \) be the cardinality of \( D \), the number of interior vertices of \( T \). The approximation \( w \in V \) is a linear combination of basis functions given by \( w = \sum_{i=1}^{n_{dof}} W_i \phi_i \), with \( W = (W_1, \ldots, W_{n_{dof}})^T \) the corresponding vector of coefficients. The discrete form of the problem (5.2) is recovered by the solution to the linear algebra system
\[
AW = F, \quad \text{with} \quad A = S + M, \quad A = (a_{ij}), \quad M = (m_{ij}), \quad F = (f_j), \quad (5.6)
\]
for stiffness matrix \( S \) and mass matrix \( M \) defined entrywise by
\[
s_{ij} = s_{ji} = \sum_{T \in \mathcal{T}} \int_T \nabla \phi_i^T \nabla \phi_j \, dx,
\]
\[
m_{ij} = m_{ji} = \sum_{T \in \mathcal{T}} \int_T \int_0^1 \frac{\partial b}{\partial \eta}(x, z(t)) \phi_i \phi_j \, dt \, dx. \quad (5.7)
\]
The load vector is given by \( f_j = \sum_{T \in \mathcal{T}} \int_T f_\delta \phi_j \, dx \). Each \( f_j \) is nonpositive, from (5.5).

From (5.6), it is sufficient to show that \( A^{-1} \) is entrywise nonnegative, to establish that each \( W_j \) is nonpositive, from which it follows that \( w \leq 0 \) and \( u_1 \leq u_2 \). This is established by showing \( A \) is a Stieltjes matrix, meaning \( A \) is symmetric positive definite with nonpositive off-diagonal entries (see for example [25, Definition 3.23]).

**Remark 5.2.** As mentioned in [7, §3.1], it is easier to show \( A \) is a Stieltjes matrix than an \( M \) matrix, as it is not necessary to show irreducibility. It also makes the current argument unsuitable for the full quasilinear problem (1.1), as the resulting linearized equation would induce a nonsymmetric matrix.

The next theorem is a restatement of [7, Theorem 3.7], reframed in the present context.

**Theorem 5.3.** Let \( u_1 \in V \) be a subsolution of (5.2), and let \( u_2 \in V \) be a supersolution of (5.2). Let \( w = u_1 - u_2 \in V \). Let \( b(x, u) \) satisfy the Assumption \([7.1]\) and for the
2D problem, let the partition satisfy Assumption 4.7. Then $T$ as given in (5.6)-(5.7) is a Stieltjes matrix, under the respective conditions for the 1D and 2D problems.

$|T| \leq \frac{6}{B_{\eta}} \min_{k=1,2,3} \cot \theta_{T,k}, \text{ for each } T \in \mathcal{T}, \text{ for } d = 2,$

$h_k^2 \leq \frac{6}{B_{\eta}}, k = 1,2,\ldots,n, \text{ for } d = 1.$

Proof. In $d$ dimensions $\int_{T} \varphi_i \varphi_j \, dx = |T|/(d+1)(d+2)$ for $i \neq j$, so the summands of the off-diagonal entries of $M$ satisfy

$\int_{T} \int_{0}^{1} \frac{\partial b(x,z(t)) \varphi_i \varphi_j}{\partial \eta} \, dt \, dx \leq \frac{B_{\eta}|T|}{(d+1)(d+2)}, i \neq j,$

and the diagonal entries of $M$ are nonnegative. By (4.8) in 2D (trivially in 1D). The diagonal entries of $S$ are positive. The off-diagonal entries of $S$ constructed by (5.7), satisfy $\int_{T} \nabla \varphi^T \nabla \varphi_j \, dx = -\cot \theta_{T,i,j}/2$ in 2D, where $\theta_{T,i,j}$ is the angle of triangle $T$ between between edges $e_i$ and $e_j$. In the 1D case, $\int_{I_k} \varphi'_k \varphi'_{k-1} \, dx = -1/h_k$.

Under the conditions (5.8) (respectively, (5.9)), and the construction (5.6)-(5.7), the matrix $A$ is symmetric positive definite with positive diagonal and nonpositive off-diagonal entries. Hence it is a Stieltjes matrix.

It follows directly from Theorem 5.3 and (5.5) that the solution $W$ to $A W = F$ is nonpositive, so that $w = u_1 - u_2 \leq 0$. This method of proof is preferred for the semilinear problem (5.1), as it gives an improved constant in the mesh condition. While it does not apply directly to the quasilinear problem (1.1), a variant using an $M$-matrix or otherwise nonsymmetric monotone matrix may be applicable.

6. Conclusion

In this paper, we proved comparision theorems in 1D and 2D for elliptic quasilinear diffusion problems discretized by standard $P_1$ finite elements, significantly extending the results of [22]. We found the discrete comparision principles hold based on conditions relating the given problem data, information about the area and angles of the mesh, and the variance of the computed solution over each mesh element. The proofs are more complicated than the comparison theorem for the continuous problem, the main setback being the positive part in the difference of two solutions does not lie in the finite element space. There remains a significant gap between the class of problems for which comparison principles hold for the PDE and for the corresponding discrete problem. For the class of problems investigated here, the discrete comparison principle implies the uniqueness of the solution to the discrete problem, based on efficiently computable conditions. These results are useful for $h$-adaptive algorithms, where the mesh presumably remains coarse away from steep gradients in the solution or (near) singularities in the data.
