We calculate the form factors for weak decays of $B(s)$ and $D(s)$ mesons to light pseudoscalar and vector mesons. To reveal the intimate connection between different decay modes and to be able to perform the calculations in the full physical $q^2$-region we use a relativistic dispersion approach based on the constituent quark picture. This approach gives the form factors as relativistic double spectral representations in terms of the wave functions of the initial and final mesons. The form factors have the correct analytic properties and satisfy general requirements of nonperturbative QCD in the heavy quark limit.

The disadvantages of quark models related to ill-defined effective quark masses and not precisely known meson wave functions are reduced by fitting the quark model parameters to lattice QCD results for the $B \to \rho$ transition form factors at large momentum transfers and to the measured total $D \to (K, K^*)l\nu$ decay rates. This allows us to predict numerous form factors for all kinematically accessible $q^2$ values.

I. INTRODUCTION

The knowledge of the weak transition form factors of heavy mesons is crucial for a proper extraction of the quark mixing parameters, for the analysis of non-leptonic decays and CP violating effects and, related to it, for a search of New Physics.

Theoretical approaches for calculating these form factors are quark models [1–8], QCD sum rules [9–12], and lattice QCD [13–16]. Although in recent years considerable progress has been made, the theoretical uncertainties are still uncomfortably large. An accuracy better than 15% has not been attained. Moreover each of the above methods has only a limited range of applicability, namely:

QCD sum rules are suitable for describing the low $q^2$ region of the form factors. The higher $q^2$ region is hard to get and higher order calculations are not likely to give real progress because of the appearance of many new parameters. The accuracy of the method cannot be arbitrarily improved because of the necessity to isolate the contribution of the states of interest from others.

Lattice QCD gives good results for the high $q^2$ region. But because of the many numerical extrapolations involved this method does not provide for a full picture of the form factors and for the relations between the various decay channels.

Quark models do provide such relations and give the form factors in the full $q^2$ range. However, quark models are not closely related to the QCD Lagrangian (or at least this relationship is not well understood yet) and therefore have input parameters which are not directly measurable and may not be of fundamental significance.

In this situation it becomes evident that a combination of various methods will be fruitful. It is the purpose of this paper to obtain this way reliable predictions for many decay form factors in their full $q^2$ ranges.

To achieve this goal, one needs a general frame for the description of the large variety of processes. This can be only a suitable quark model, because only a quark model can connect different processes through the soft wave functions of the mesons and describes the full $q^2$ range of the form factors. The predictions of this model will be much improved by incorporating the results from the more fundamental QCD based methods.

Historically, constituent quark models have been first to analyse the meson transition form factors. Although a rigorous derivation of this approach as an effective theory of QCD in the nonperturbative regime has not been obtained, relativistic quark models work surprisingly well for the description of the meson spectra and form factors. Moreover, constituent quark models provide so far the only operative method for dealing with excited states.

---

1One of the first steps in combining various approaches in order to obtain predictions for the form factors for all $q^2$ has been done in [14] where a simple lattice-constrained parametrization based on the constituent quark picture of Ref. [17] and pole dominance has been proposed.
1. The physical picture

Constituent quark models are based on the following phenomena expected from QCD:

i) chiral symmetry breaking in the low-energy region provides for the masses of the constituent quarks;

ii) the strong peaking of the soft (nonperturbative) hadronic wave functions in terms of the quark momenta with a width of the order of the confinement scale; and

iii) the dominance of Fock states with the minimal number of constituents, i.e. a $q\bar{q}$ composition of mesons.

An important shortcoming of previous quark model predictions was a strong dependence of the results on the special form of the quark model and on the parameter values.

The goal of this paper is to demonstrate that once (a) a proper relativistic formalism is used for the description of the transition form factors and (b) the numerical parameters of the model are chosen properly (we discuss criteria for such a proper choice below), the quark model yields results in full agreement with existing experimental data and in accord with the predictions of more fundamental theoretical approaches. In addition, our quark model allows to predict many other form factors which have not yet been measured.

2. The formalism

For the description of the transition form factors in their full $q^2$ range and for various initial and final mesons, a fully relativistic treatment is necessary. We therefore choose a formulation of the quark model which is based on the relativistic dispersion approach [13] and thus guarantees the correct spectral and analytic properties.

Within this model, the transition form factors are given by relativistic double spectral representations through the wave functions of the initial and final mesons both in the scattering and the decay regions. These spectral representations obey rigorous constraints from QCD on the structure of the long-distance corrections in the heavy quark limit. Namely, the form factors of the dispersion quark model have the correct heavy-quark expansion at leading and next-to-leading $1/m_Q$ orders in accordance with QCD for transitions between heavy quarks [19,20]. For the heavy-to-light transition the dispersion quark model satisfies the relations between the form factors of vector, axial-vector, and tensor currents valid at small recoil [21]. In the limit of the heavy-to-light transitions at small $q^2$ the form factors obey the lowest order $1/m_Q$ and $1/E$ relations of the Large Energy Effective Theory [24] and provide the pattern of higher-order symmetry-violating effects.

Another important advantage of the dispersion formulation of the quark model is the fact that one directly obtains the form factors in the physical decay region $q^2 > 0$. No numerical extrapolation from space-like values is required.

3. Parameters of the model

In previous applications of quark models the transition form factors turned out to be sensitive to the numerical parameters, such as the quark masses and the slopes of the meson wave functions. As proposed in Ref. [23], the way to control these parameters is to use the results of lattice calculations at large $q^2$ as 'experimental' inputs. In [24] the $b$ and $u$ constituent quark masses and slope parameters of the $B$, $\pi$, and $\rho$ wave functions have been obtained through this procedure.

We now consider in addition the charm and strange mesons. To determine the slope parameters for the charm and strange meson wave functions and the effective mass values $m_c$ and $m_s$ we use here as input the measured total rates for the decays $D \rightarrow (K, K^*)\ell\nu$. By fixing the parameters in this way we overcome important uncertainties inherent in quark model calculations. Indeed, with these few inputs we can give numerous predictions for the form factors for the transitions of the heavy and strange heavy mesons $D$, $D_s$, $B$, and $B_s$ into light mesons which nicely agree at places where data are available.

The paper is organized as follows. Section II briefly presents the main features of the double spectral representations of the form factors. In Section III we determine the numerical parameters of the model and give the predictions of the form factors. Section IV contains our conclusions.

II. MESON TRANSITION FORM FACTORS

The long-distance contribution to meson decays is contained in the relativistic invariant transition form factors of the vector, axial-vector and tensor currents. The amplitudes of the $M_1 \rightarrow M_2$ transition induced by the weak $q_2 \rightarrow q_1$ quark transition through the vector $V_\mu = \bar{q}_1\gamma_\mu q_2$, axial-vector $A_\mu = \bar{q}_1\gamma_\mu\gamma_5 q_2$, tensor $T_{\mu\nu} = \bar{q}_1\sigma_{\mu\nu}q_2$, and pseudotensor $T^3_{\mu\nu} = \bar{q}_1\sigma_{\mu\nu}\gamma_5 q_2$ currents, have the following covariant structure [21].
The initial pseudoscalar meson vertex has the spinorial structure $\Gamma$ of the quark model \[18\]. We start by considering the region $q^2$ structure $\Gamma$ the structure of the heavy quark expansion in the quark model to the structure of the heavy-quark expansion in QCD.

The quark structure of the initial and final mesons is given in terms of the vertices $\Gamma$ For constructing the double spectral representation we must consider a double–cut graph where all intermediate Lorentz structures depending on $\tilde{q}$ induced by the quark transition $\Gamma$. For the quark transition $\Gamma$ we have $s = 2m_1^2 + m_2^2 - q^2$, and $S_{\mu\nu}(\tilde{q},\nu,m)$, $s_{\mu\nu}(\tilde{q},\nu,m)$ are the Pauli–Lubin–Ioffe tensors. We study the form factors within the dispersion formulation of the quark model \[18\]. We start by considering the region $q^2 < 0$ where the form factors may be represented as double spectral representations in the invariant masses of the initial and final $q\bar{q}$ pairs. The form factors corresponding to the decay region $q^2 > 0$ are then derived by performing the analytical continuation.

The transition of the initial meson $q(m_1)\bar{q}(m_3)$ with the mass $M_1$ to the final meson $q(m_1)\bar{q}(m_3)$ with the mass $M_2$ induced by the quark transition $q(m_2) \rightarrow q(m_1)$ through the current $\bar{q}(m_1)O_\mu q(m_2)$ is described by the diagram of Fig.1. For constructing the double spectral representation we must consider a double–cut graph where all intermediate particles go on mass shell but the initial and final mesons have the off–shell momenta $\tilde{p}_1$ and $\tilde{p}_2$ such that $\tilde{p}_1^2 = s_1$ and $\tilde{p}_2^2 = s_2$ with $(\tilde{p}_1 - \tilde{p}_2)^2 = q^2$ kept fixed.

![FIG. 1. One-loop graph for a meson decay.](image)

The quark structure of the initial and final mesons is given in terms of the vertices $\Gamma_1$ and $\Gamma_2$, respectively. The initial pseudoscalar meson vertex has the spinorial structure $\Gamma_1 = i\gamma_5G_1/\sqrt{N_c}$; the final meson vertex has the structure $\Gamma_2 = i\gamma_5G_2/\sqrt{N_c}$ for a pseudoscalar state and the structure $\Gamma_{2\mu} = [A\gamma_\mu + B(k_1 - k_3)\mu]G_2/\sqrt{N_c}$, $A = -1, B = 1/(\sqrt{s_2} + m_1 + m_3)$ for an $S$–wave vector meson.

The double spectral densities $f$ of the form factors are obtained by calculating the relevant traces and isolating the Lorentz structures depending on $\tilde{p}_1$ and $\tilde{p}_2$. These invariant factors $\tilde{f}$ account for the two–particle singularities in the Feynman graph.

For $q^2 < 0$ the spectral representations of the form factors have the form \[18\]

$$f_i(q^2) = \frac{1}{16\pi^2} \int_{(m_1+m_3)^2}^{\infty} ds_2 \varphi_2(s_2) \int_{s_1^{-}(s_2,q^2)}^{s_1^{+}(s_2,q^2)} ds_1 \varphi_1(s_1) \tilde{f}_i(s_1,s_2,q^2) \lambda^{1/2}(s_1,s_2,q^2),$$  \hspace{1cm} (2)

where the wave function $\varphi_1(s_1) = G_1(s_1)/(s_1 - M_1^2)$ and

$$s_1^{\pm}(s_2,q^2) = \frac{s_2(m_1^2 + m_2^2 - q^2) + q^2(m_1^2 + m_2^2) - (m_1^2 - m_2^2)(m_1^2 - m_3^2)}{2m_1^2} \pm \frac{\lambda^{1/2}(s_2,m_3^2,m_1^2)\lambda^{1/2}(q^2,m_1^2,m_2^2)}{2m_1^2}$$

and $\lambda(s_1,s_2,s_3) = (s_1 + s_2 - s_3)^2 - 4s_1s_2$ is the triangle function \[1\]. The analytical continuation of the expression \[2\]

\[2\]The spectral densities $\tilde{f}$ include proper subtraction terms. These subtraction terms have been determined in \[18\] by matching the structure of the heavy quark expansion in the quark model to the structure of the heavy-quark expansion in QCD

---

3
to the region $q^2 > 0$ gives the form factor at $q^2 \leq (m_2 - m_1)^2$. Explicit expressions of the double spectral densities of all the form factors in [6] and more details can be found in [18].

The soft wave function of a meson $M \{q(m_q)\bar{q}(m_{\bar{q}})\}$ can be written as follows

$$
\varphi(s) = \frac{\pi}{\sqrt{2}} \frac{\sqrt{s^2 - (m_2 - m_3)^2}}{w(k^2)} \frac{1}{s^{3/2}}
$$

with $k^2 = \lambda(s, m_2^2, m_3^2)/4s$. Here the ground-state radial $S$-wave function $w(k^2)$ is normalized as $\int w^2(k^2)k^2 dk = 1$.

As demonstrated in [18] the form factors develop the correct structure of the long-distance corrections in accordance with QCD in the leading and next-to-leading order, if the radial wave functions $w(k^2)$ are localized in a region of the order of the confinement scale, $k^2 \lesssim \Lambda^2$. We assume a simple Gaussian parametrization of the radial wave function

$$
w(k^2) \propto \exp(-k^2/2\beta^2),
$$

which satisfies the localization requirement for $\beta \simeq \Lambda_{QCD}$.

The leptonic decay constant of the pseudoscalar meson $f_P$ is given in terms of its wave function by the spectral representation [18]

$$
f_P = \sqrt{N_c(m_q + m_{\bar{q}})} \int ds \varphi(s) \frac{\chi^{1/2}(s, m_q^2, m_{\bar{q}}^2)}{8\pi^2 s} \frac{s - (m_q - m_{\bar{q}})^2}{s}.
$$

### III. PARAMETERS OF THE MODEL AND NUMERICAL RESULTS

#### A. Parameters of the model

We consider the slope parameter $\beta$ of the meson wave function [6] and the constituent quark masses as fit parameters. The relevant values for the $B$, $\rho$, and $\pi$ mesons have already been determined in [24] from a fit to the lattice results on the form factors $T_2(q^2)$ and $A_1(q^2)$ (see Eq. (7) below) at $q^2 = 19.6$ and 17.6 GeV$^2$ [14]. Thereby, use has been made of the spectral representation of the leptonic decay constant [6], and the double spectral representations [6] of the form factors. The values obtained for $m_b$, $m_u$, and $\beta_B$, $\beta_{\rho}$, $\beta_\pi$ are displayed in Table [6].

A few comments on these numbers are in order:

- The quark model double spectral representations take into account long-range QCD effects but not the short-range perturbative corrections. However, by fitting the wave functions and masses to reproduce the lattice points, these corrections are effectively taken care of: Corrections to the quark propagators correspond to the appearance of the effective quark masses. Corrections to the vertices at the relevant values of the recoil variable $\omega = (M_B^2 + m_q^2 - q^2)/2M_Bm_q$ should be small as found in form factors of other meson transitions [20].

- The value obtained for the $b$-quark mass $m_b = 4.85$ GeV is close to the one-loop pole mass which in fact is the relevant mass for quark model calculations.

We now need to fix the parameters describing the strange and charmed mesons. The charm quark mass can be determined from the well-known $1/m_Q$ expansion of the heavy meson mass in terms of the heavy quark mass and the hadronic parameters $\Lambda$, $\lambda_1$ and $\lambda_2$. Using the recent estimates of these parameters [27] one finds

$$
m_b - m_c \simeq 3.4 \text{ GeV}.
$$

This provides $m_c \simeq 1.45$ GeV. For $m_s$ one expects $m_s \simeq 350 - 370$ MeV taking into account that $m_u = 230$ MeV.
A stringent way to constrain the parameters $m_s$, $\beta_K$, $\beta_{K^*}$, and $\beta_D$ is provided by the measured integrated rates of the semileptonic decays $D \to (K, K^*)\ell\nu$. In addition we apply the relation (3) which connects $\beta_K$ with $m_s$ by using the known value of the $K$-meson leptonic decay constant $f_K = 160 \text{MeV}$. The parameter values found this way are displayed in Table III. The corresponding form factors and decay rates are given in Tables IV and V.

The polarization of the $K^*$ in the $D \to K^*\ell\nu$ decays turns out to be in good agreement with the experimental result (Table VI), and the calculated $D$ meson decay constant $f_D = 200 \text{MeV}$ corresponds to the expectation for the magnitude of this quantity.

The parameter $\beta_D^*$ cannot be found this way, but it should be close to $\beta_D$ because of the heavy quark symmetry requirements. We therefore set $\beta_D^* = \beta_D$.

Also listed in Table III are the parameters which describe strange heavy mesons. They are discussed in subsection D.

The knowledge of the wave functions and the quark masses allows the calculation of the form factors in Eq. (4). It is however more convenient to present our results in terms of the dimensionless form factors $F_+, F_0, f_T, V, A_0, A_1, A_2, T_1, T_2, T_3$ [3] which are the following linear combinations of the form factors given in Eq. (3):

$$
F_+ = f_+, \quad F_0 = f_+ + \frac{q^2}{Pq} f_-, \quad F_T = -(M_1 + M_2)s, \\
V = (M_1 + M_2)g, \quad A_1 = \frac{1}{M_1 + M_2} f, \quad A_2 = -(M_1 + M_2) a_+, \quad A_0 = \frac{1}{2M_2} (f + q^2 \cdot a_- + Pq \cdot a_+), \\
T_1 = -g_-, \quad T_2 = -g_+ - \frac{q^2}{Pq} g_-, \quad T_3 = g_+ - \frac{Pq}{2} \cdot g_0.
$$

The form factors (7) are defined such that they involve only contributions of resonances in the $q^2$ channel with the same spin, whereas some of the form factors defined by the Eq. (4) contain contributions of resonances with different spins. The form factors $F_+, F_T, V, T_1$ contain a pole at $q^2 = M_V^2 \equiv M_{1^+}^2$, and $A_0$ contains a pole at $q^2 = M_B \equiv M_{0^-}^2$ (more details are given in the Appendix).

The remaining form factors, $F_0, A_1, A_2, T_2$ and $T_3$, do not contain contributions of the lowest lying negative parity states (for instance, $F_0$ contains a contribution of the $0^+$ state, and $A_1$ contains that of the $1^+$ which have considerably higher masses). As a result they have a rather flat $q^2$ behaviour in the decay region, whereas the form factors $F_+, F_T, V, T_1, A_0$ are rising more steeply.

From the spectral representations (3) together with the parameter values of Table I the form factors are obtained numerically. For the applications it is convenient, however, to represent our results by simple fit formulas which interpolate these numerical values within a 1% accuracy for all $q^2$ values in the region $0 < q^2 < (m_2 - m_1)^2$. Also, they should be appropriate for a simple extrapolation to the resonance region.

---

4 In [23] a different set of the parameters was used which also provided a good description of the available experimental data on semileptonic $B$ and $D$ decays. However, the corresponding form factors have a rather flat $q^2$-dependence and do not match the lattice results at large $q^2$. 

---

5
Let us start with the form factors $F_+, F_T, V, T_1, A_0$. If we interpolate the results of the calculation with the simple three-parameter fit formula

$$f(q^2) = \frac{f(0)}{(1 - q^2/M^2)(1 - q^2/(\alpha M)^2)},$$

(8)

the least-$\chi^2$ interpolation procedure leads in all cases to a value of the parameter $M$ which is within 3% equal to the lowest resonance mass. We consider this fact to be an important indication for the proper choice of the quark-model parameters and for the reliability of our calculations. We therefore prefer to fix the pole mass $M$ to its physical value. The fit functions (8) represent the results now with an accuracy of less than 2%. To achieve the accuracy of less than 1% in all cases we take the form $[24]$:

$$f(q^2) = \frac{f(0)}{(1 - q^2/M^2)[1 - \sigma_1 q^2/M^2 + \sigma_2 q^4/M^4]},$$

(9)

where $M = M_P$ for the form factor $A_0$ and $M = M_V$ for the form factors $F_+, F_T, V, T_1$. In the Tables below we quote numerical values of $\sigma_2$ only if an accuracy of better than 1% cannot be achieved with $\sigma_2 = 0$, and take $\sigma_2 = 0$ if this accuracy can already be achieved with the two parameters $f(0)$ and $\sigma_1$. A two-parameter fit was discussed in $[28]$. For the heavy-to-light meson transitions the masses of the lowest resonances are not very much different from the highest $q^2$ values in the decay. Eq. (9) then allows an estimate of the residues of these poles. These residues can be expressed in terms of products of weak and strong coupling constants (see Appendix). The errors for these constants induced by changing $\sigma_1$ and $\sigma_2$ in our fitting procedure (keeping to the 1% requirement) do not exceed 10%. Moreover, the residues of the form factors at the meson pole are not independent and satisfy certain constraint (see Eq. (18) in the Appendix), which provides a consistency check of the extrapolations. The mismatch in (18) is always below 10%, and in most of the cases much lower.

For the form factors $F_0, A_1, A_2, T_2$ and $T_3$ the contributing resonances (0+, 1+, etc) lie farther away from the physical decay region and the effect of any particular resonance is smeared out. For these form factors the interpolation formula taken is:

$$f(q^2) = f(0)/[1 - \sigma_1 q^2/M_V^2 + \sigma_2 q^4/M_V^4].$$

(10)

If setting $\sigma_2 = 0$ allows us to describe the calculation results with better than 1% accuracy for all $q^2$, a simple monopole two-parameter formula is used.

The values of $f(0)$, $\sigma_1$, and $\sigma_2$ are given for each decay mode in the relevant subsections.

### B. Charmed meson decays

#### 1. $D \rightarrow K, K^*$

The $D \rightarrow K, K^*$ decays are induced by the charged current $c \rightarrow s$ quark transition. As described in the previous section, the measured total rates of these decays are used for a precise fit of the parameters of our model. With the parameters of Table I we obtain the form factors listed in Table IV. Table V compares the form factors at $q^2 = 0$ with the results of other approaches and Table VI presents the decay rates.

| $D \rightarrow K$ | $D \rightarrow K^*$ |
|------------------|---------------------|
| $f(0)$ | $F_+$ | $F_0$ | $F_T$ | $V$ | $A_0$ | $A_1$ | $A_2$ | $T_1$ | $T_2$ | $T_3$ |
| 0.78 | 0.78 | 0.75 | 1.03 | 0.76 | 0.66 | 0.49 | 0.78 | 0.78 | 0.45 |
| $\sigma_1$ | 0.24 | 0.38 | 0.27 | 0.27 | 0.17 | 0.30 | 0.67 | 0.25 | 0.02 | 1.23 |
| $\sigma_2$ | 0.46 | 0.27 | 0.27 | 0.27 | 0.20 | 0.16 | 1.80 | 0.34 |

One should note that the parameters $\sigma_1$ and $\sigma_2$ in the fit formula $[11]$ for the form factors $F_0, A_1, A_2, T_2$, and $T_3$ are introduced in a different way than in the fit formula $[10]$ for the form factors $F_+, F_T, V, T_1$, and $A_0$. 

---

5 One should note that the parameters $\sigma_1$ and $\sigma_2$ in the fit formula $[11]$ for the form factors $F_0, A_1, A_2, T_2$, and $T_3$ are introduced in a different way than in the fit formula $[10]$ for the form factors $F_+, F_T, V, T_1$, and $A_0$. 

---

Extrapolating the form factors to $q^2 = M_{D^*}^2$, (or $q^2 = M_D^2$ for $A_0$) gives the following estimates of the coupling constants (see the Appendix for the relevant formulas):

$$\frac{g_{D^*DK} f_V^{(D^*)}}{2M_{D^*}} = 1.05 \pm 0.05,$$

$$\frac{g_{D^*DK} f_T^{(D^*)}}{2M_{K^*}} = 1.7 \pm 0.1,$$

$$\frac{f_V^{(D^*)}}{f_T^{(D^*)}} = 0.95 \pm 0.05,$$

$$\frac{g_{D^*DK^*}}{g_{D^*DK}} = 1.1 \pm 0.1.$$

2. $D \to \pi, \rho$

These decays are induced by the $c \to d$ charged current. Since all the necessary parameters have already been fixed, this mode allows for parameter-free predictions. Table VII presents the results of our calculations. In Tables VIII and IX we compare our results with different approaches and with experimental data. The form factors at $q^2 = 0$ are close to the predictions of the relativistic quark model of Ref. [4], but the $q^2$ dependence is different such that our model and [4] predict different decay rates. Although the experimental errors are very large and nearly all theoretical results agree with experiment, we notice perfect agreement of our decay rates with the central values.

TABLE VII. The calculated $D \to \pi, \rho$ transition form factors. $M_V = M_{D^*} = 2.01$ GeV, $M_P = M_D = 1.87$ GeV. For the form factors $F_+, F_T, V, A_0, T_1$ the fit formula Eq. (9) is used, for the other form factors - Eq. (10).

|       | $D \to \pi$ | $D \to \rho$ |

| This work     | 0.95                          | 0.42                          | 0.45                        | 1.16                |
| WSB [1]       | 0.68                          | 0.67                          | 1.0                         | 0.91                |
| Jaus’96 [2]   | 0.8                           | 0.33                          | 0.41                        | 1.22                |
| SR [3]        | 0.39(8)                       | 0.12(4)                       | –                           | 1.31(11)            |
| Melikhov’97 [25] | 0.62                     | 0.26                          | 0.41                        | 1.27                |
| Exp [32]      | 0.92(45)                      | 0.45(22)                      | 0.50(35)                    | –                   |

For the coupling constants we get the following relations:

$$\frac{g_{D^*D\pi} f_V^{(D^*)}}{2M_{D^*}} = 1.05 \pm 0.05,$$

$$\frac{g_{D^*D\rho} f_P^{(D)}}{2M_\rho} = 2.1 \pm 0.2,$$

$$\frac{f_T^{(D^*)}}{f_V^{(D^*)}} = 0.9 \pm 0.1,$$

$$\frac{g_{D^*D\rho}}{g_{D^*D\pi}} = 1.3 \pm 0.2.$$

Taking $f_V^{(D^*)} \approx 220$ MeV, we find

$$g_{D^*D\pi} = 18 \pm 3$$

in perfect agreement with a calculation of $g_{D^*D\pi}$ based on combining PCAC with the dispersion approach [35].

**C. Beauty meson decays**

1. $B \rightarrow D, D^*$

These decays arise from the heavy-quark $b \rightarrow c$ transition. Here one has rigorous predictions for the expansion of the form factors in terms of the heavy-quark mass $m_b$ [20]. Namely, the main part of the form factors can be expressed through the universal form factor - the Isgur-Wise function. However, different models provide different $q^2$-dependences of the Isgur-Wise function as well as different subleading $1/m_Q$ corrections.

We recall that our spectral representations of the form factors explicitly respect the structure of the long-distance QCD corrections in the leading and the subleading orders of the heavy-quark expansion. Thus, we expect reliable predictions for the form factors. Our numerical results are summarized in Tables X, XI, and XII.

**TABLE X.** The calculated $B \rightarrow D, D^*$ transition form factors. $M_V = M_{B^*} \approx M_{D^*} = M_{B_c} = 6.4$ GeV. For the form factors $F_+, F_T, V, A_0, T_1$ the fit formula Eq. (9) is used, for the other form factors - Eq. (10).

For the coupling constants we find

$$\frac{g_{B^*BD}f^{(B^*_0)}}{2M_{B^*_0}} = 1.56 ± 0.15, \quad \frac{g_{B^*BD}f^{(B_s)}}{2M_{D^*_s}} = 3.3 ± 0.3, \quad \frac{f_T^{(B^*_0)}}{f_V^{(B^*_0)}} = 0.9 ± 0.1, \quad \frac{g_{B^*BD}}{g_{B^*DD}} = 1.05 ± 0.05.$$

2. $B \to K, K^*$

These decays are induced by the $b \to s$ Flavor Changing Neutral Current (FCNC). We recall that the $B \to \pi, \rho$ form factors at large $q^2$ have been used to fix the parameters of the model. Thus we expect that the predictions for the $B \to K, K^*$ form factors which in fact differ from the former mode only by SU(3) violating effects should be particularly reliable. Table XIII presents the calculated form factors and Fig. 2 exhibits our predictions together with the available lattice results at large $q^2$. The good agreement shows that the size and the sign of the SU(3) violating effects are correctly accounted for.

TABLE XIII. The calculated $B \to K, K^*$ transition form factors. $M_V = M_{B^*_0} = 5.42$ GeV, $M_P = M_{B^*_s} = 5.37$ GeV. For the form factors $F_+, F_T, V, A_0, T_1$ the fit formula Eq. (9) is used, for the other form factors - Eq. (10).

FIG. 2. Form factors of the $B \to K^*$ transition vs the lattice results.
For the coupling constants we obtain

\[
\frac{g_{B^*}B^*f_{V(0)}^{(B^*)}}{2M_{B^*}} = 0.65 \pm 0.05, \quad \frac{g_{B^*}B^*f_{P(0)}^{(B^*)}}{2M_{B^*}} = 1.65 \pm 0.1, \quad \frac{f_T^{(B^*)}}{f_V^{(B^*)}} = 0.95 \pm 0.05, \quad \frac{g_{B^*}B^*}{g_{B^*}B^*} = 1.15 \pm 0.05.
\]

3. $B \to \pi, \rho$

The $B \to \rho$ transition has been used for determining the parameters of our quark model in the $u, d$ and $b$ sectors by fitting the quark-model form factors to available lattice results on $T_2$ and $A_1$ at large $q^2$ in [24]. The corresponding form factors and the decay rates have been calculated in this article. We present the results of [24] in terms of parametrizations for the form factors of the set (8) (see Table XV) which have not been given in that paper. The only difference of the results presented here with the results of [24] occurs for the $B \to \pi$ form factors $F_+$ and $F_0$ at $q^2 \geq 20$ GeV$^2$. In [24] these quantities are not calculated directly but extrapolated from the region $q^2 \leq 20$ GeV$^2$. The parametrizations of $f_+$ and $f_-$ in [24] correspond to $g_{B^*\pi} \approx 50$. The parametrization given here, on the other hand, corresponds to $g_{B^*\pi} \approx 32$ which is in agreement with recent analyses of this quantity [15,11]. At $q^2 \leq 20$ GeV$^2$ both parametrizations describe the results of the numerical calculation well and agree with the available results from lattice QCD at $q^2 \leq 22$ GeV$^2$ [10]. For these reasons, the earlier result $\Gamma(B \to \pi\nu) = 8.3|V_{ub}|^2$ ps$^{-1}$ calculated with the parametrization of the form factor $F_+$ from Table XV remains practically unchanged compared to [24].

The form factor $F_0$ at large $q^2$ lies below the central lattice values but nevertheless agrees with lattice results within the given error bars. Notice however that in our model the form factor $F_0$ is calculated as a difference of $f_+$ and $f_-$ and at large $q^2$ turns out to be much more sensitive to the subtle details of the pion wave function, than $f_+$ and $f_-$ separately. A simple Gaussian wave function which works quite well for $f_+$ and $f_-$, might not be sufficiently accurate for $F_0$.

TABLE XV. The calculated $B \to \pi, \rho$ transition form factors. $M_V = M_{B^*} = 5.32$ GeV, $M_P = M_{B^*} = 5.27$ GeV. For the form factors $F_+, F_-, V, A_0, T_1$ the fit formula Eq. (3) is used, for the other form factors - Eq. (10).

|       | $B \to \pi$         | $B \to \rho$         |
|-------|---------------------|---------------------|
|       | $F_0$ | $F_0$ | $F_0$ | $V$ | $A_0$ | $A_0$ | $A_0$ | $T_1$ | $T_2$ | $T_3$ |
| $f(0)$ | 0.29  | 0.29  | 0.29  | 0.31 | 0.30  | 0.26  | 0.24  | 0.27  | 0.27  | 0.19  |
| $\sigma_1$ | 0.48  | 0.76  | 0.48  | 0.59 | 0.54  | 0.73  | 1.40  | 0.60  | 0.74  | 1.42  |
| $\sigma_2$ | 0.28  | 0.28  | 0.28  | 0.26 | 0.26  | 0.26  | 0.26  | 0.22  | 0.37  | 0.29  |

Table XVI compares the results obtained from the quark model of Ref. [24] with results from the quark model of Jaus [11] and latest light-cone sum rule (LCSR) results [11]. One observes very good agreement between the quark model of Jaus, LCSRs, and our approach. The only visible difference with the LCSR method occurs in the form factor $A_0(0)$, which is caused by small differences of the two methods in $A_1(0)$ and $A_2(0)$ (recall that $A_0(0) = ((M_1 + M_2)A_1(0) - (M_1 - M_2)A_2(0))/2M_2$). This discrepancy exceeds the 15% error bar quoted for the LCSR results only marginally. If the LCSR results at small $q^2$ and lattice results at large $q^2$ are correct, our approach surely provides a realistic description of the form factors at all kinematically accessible $q^2$ values.

TABLE XVI. Comparison of the results of different approaches on weak $B \to \pi, \rho$ form factors at $q^2 = 0$.

| Ref.       | $F_0(0)$ | $F_T(0)$ | $V(0)$ | $A_0(0)$ | $A_0(0)$ | $A_0(0)$ | $T_1(0)$ | $T_2(0)$ | $T_3(0)$ |
|------------|----------|----------|--------|----------|----------|----------|----------|----------|----------|
| This work  | 0.29     | 0.28     | 0.31   | 0.26     | 0.24     | 0.29     | 0.27     | 0.19     |
| Jaus ’96   | 0.27     | -        | 0.35   | 0.26     | 0.24     | -        | -        | -        |
| LCSR ’98   | 0.305    | 0.296    | 0.34   | 0.26     | 0.22     | 0.37     | 0.29     | 0.20     |
| Lat [10]   | 0.28[4]  | 0.28(7)  | -      | -        | -        | -        | -        | -        |

Extrapolating the form factors to the poles, we obtain

\[
\frac{g_{B^*\pi f_{V(0)}^{(B^*)}}}{2M_{B^*}} = 0.6 \pm 0.05, \quad \frac{g_{B^*\pi f_{P(0)}^{(B^*)}}}{2M_{B^*}} = 1.4 \pm 0.2, \quad \frac{f_T^{(B^*)}}{f_V^{(B^*)}} = 0.97 \pm 0.03, \quad \frac{g_{B^*\pi}}{g_{B^*\pi}} = 1.2 \pm 0.1.
\]

Using $f_V^{B^*} \approx 200$ MeV gives the estimate

\[
g_{BB^*\pi} = 32 \pm 5, \quad \hat{g} = \frac{f_{B^*}}{2\sqrt{M_B M_{B^*}}} g_{BB^*\pi} = 0.4 \pm 0.06
\] (11)
The latter value is in good agreement with the lattice result \( \hat{g} = 0.42 \pm 0.04 \pm 0.08 \) \cite{44} and is only slightly smaller than \( \hat{g} = 0.5 \pm 0.02 \) \cite{33} based on combining PCAC with our dispersion approach.

Summing up our results on the decays of the nonstrange heavy mesons, we found no disagreement neither with the existing experimental data nor with the available results of the lattice QCD or sum rules in their specific regions of validity. The only exception is the form factor \( F \) existing experimental data nor with the available results of the lattice QCD or sum rules in their specific regions of \( q^2 \) lying slightly below the lattice points. However, this disagreement can be related to a strong sensitivity of \( f_0^\pi \) and \( f_0^\pi \), can change the form factor \( F_0 \), but such subtle effects are beyond the scope of our present analysis.

In the next section we apply our model to the decays of strange heavy mesons for which a few new parameters have to be introduced which are specific to the description of weak decays of strange heavy mesons to light mesons.

\section*{D. Decays of the strange mesons \( D_s \) and \( B_s \)}

Before dealing with these decays, we must first specify the slope parameters of the \( B_s \) and the \( D_s \) wave function. We obtain these parameters by applying (9) and using \( f_{B_0}/f_B = 1.1 \) and \( f_{D_0}/f_D = 1.1 \) in agreement with the lattice estimates for these quantities \cite{33}. The resulting values of the slope parameters are listed in Table \ref{table:v}. Since all other parameters have already been fixed the calculation of the form factors is straightforward. The only exceptions are the decays into the \( \eta, \eta' \), final states. For these decays we need to know the \( \phi \) wave function, the mixing angle and the slope of the radial wave function of the \( s\bar{s} \) component in \( \eta \) and \( \eta' \). Our procedure of fixing these parameters are discussed in the relevant subsection.

\subsection*{1. \( D_s \to K, K^\ast \)}

These meson transition are driven by the charged-current \( c \to d \) quark transition. The results of the calculation are given in Table \ref{table:x}. The predictions for the semileptonic decay rates are displayed in Table \ref{table:y}.

\begin{table}[h]
\centering
\caption{The calculated \( D_s \to K, K^\ast \) transition form factors. \( M_V = M_{D^\ast} = 2.01 \text{ GeV} \), \( M_P = M_D = 1.87 \text{ GeV} \). For the form factors \( F_s, F_T, V, A_0, T_1 \) the fit formula Eq. (9) is used, for the other form factors - Eq. (10).}

\end{table}

For the coupling constants we obtain

\[
\frac{g_{D^\ast D, K}f^{(D^\ast)}_V}{2M_{D^\ast}} = 0.95 \pm 0.05, \quad \frac{g_{D D, K^\ast}f^{(D)}_P}{2M_{K^\ast}} = 1.85 \pm 0.15, \quad \frac{f^{(D^\ast)}_T}{f^{(D^\ast)}_V} = 0.9 \pm 0.1, \quad \frac{g_{D^\ast D, K}}{g_{D^\ast D, K}} = 1.15 \pm 0.15.
\]
2. \( D_s \rightarrow \eta, \eta', \phi \)

These decay modes are induced by the charged current \( c \rightarrow s \) quark transition. The pseudoscalar mesons \( \eta \) and \( \eta' \) are mixtures of the nonstrange and the strange components with the flavour wave functions \( \eta_n = \frac{u_d + d_s}{\sqrt{2}} \) and \( \eta_s = \bar{s}s \), respectively,

\[
\eta = \cos(\varphi) \eta_n - \sin(\varphi) \eta_s \\
\eta' = \sin(\varphi) \eta_n + \cos(\varphi) \eta_s,
\]

with the angle \( \varphi \approx 40^\circ \). The decay rates of interest are

\[
\Gamma(D_s \rightarrow \eta l\nu) = \sin^2(\varphi) \Gamma(D_s \rightarrow \eta_s(M_{\eta})) l\nu \\
\Gamma(D_s \rightarrow \eta' l\nu) = \cos^2(\varphi) \Gamma(D_s \rightarrow \eta_s(M_{\eta'})) l\nu.
\]

Let us give a brief explanation of these formulas: The semileptonic decay rates are determined by the form factor \( f_+ \) with the angle \( \varphi \). On the other hand, the phase-space volume of the decay process is determined by the Hamiltonian and does not have a definite mass. This means that for the \( \bar{s}s \) component of both \( \eta \) and \( \eta' \) we have to deal with the same form factor, which can be expressed through the radial wave function of this component. Of the other hand, the phase-space volume of the decay process is determined by the physical meson masses, as indicated in Eq. (13). It should be clear, however, that the \( \eta_s \) is not an eigenstate of the Hamiltonian and does not have a definite mass.

Assuming universality of the wave functions of the ground state pseudoscalar \( 0^- \) nonet, the radial wave function of the nonstrange component \( \Psi_{\eta_n} \) coincides with the pion radial wave function. The radial wave function \( \Psi_{\eta_s} \) should be determined independently. From the analysis of a broad set of processes the leptonic decay constant of the nonstrange component \( \eta_n \), has been found to lie in the interval \( f_\pi = (1.36 \pm 0.04)f_\pi \). This allows us to determine the slope parameter \( \beta_{\eta_n} = 0.45 \). For the slope parameter \( \beta_\phi \) of the wave function of the \( \phi \)-meson, which is the vector \( \bar{s}s \) state, we expect a value close to \( \beta_{\eta_n} \).

In fact, \( \beta_\phi = 0.45 \) GeV leads to the \( B_s \rightarrow \phi \) transition form factors which agrees well with the LCSR results at \( q^2 = 0 \) (see subsection 4). With all other quark model parameters fixed from the description of the nonstrange heavy meson decays and by taking a simple Gaussian form of the radial wave function, the decay rate \( \Gamma(D_s \rightarrow \phi l\nu) \) is a function of \( \beta_\phi \). This function has a minimum at the value \( \beta_\phi = 0.45 \) GeV; nevertheless, the corresponding value of the decay rate is \( 1\sigma \) above the central experimental value.

The results of our calculations are given in Tables XIX and XX.

**TABLE XIX.** The calculated \( D_s \rightarrow \eta, \phi \) transition form factors. \( M_V = M_{D_s} = 2.11 \) GeV, \( M_P = M_{D_{s'}} = 1.97 \) GeV. For the form factors \( F_F, F_T, V, A_0, A_1, A_2, T_1, T_2, T_3 \) the fit formula Eq. (10) is used, for the other form factors - Eq. (11).

| \( D_s \rightarrow \eta(M_{\eta}) \) | \( D_s \rightarrow \eta(M_{\eta'}) \) | \( D_s \rightarrow \phi \) |
|---|---|---|
| \( f(0) \) | \( f_0 \) | \( f_0 \) | \( f_0 \) | \( f_T \) | \( f_T \) | \( V \) | \( A_0 \) | \( A_1 \) | \( A_2 \) | \( T_1 \) | \( T_2 \) | \( T_3 \) |
| 0.78 | 0.78 | 0.80 | 0.78 | 0.94 | 1.10 | 0.73 | 0.64 | 0.47 | 0.77 | 0.77 | 0.46 |
| \( \sigma_1 \) | 0.23 | 0.33 | 0.24 | 0.21 | 0.24 | 0.26 | 0.10 | 0.29 | 0.63 | 0.25 | 0.02 | 1.34 |

**TABLE XX.** The \( D_s \rightarrow (\eta, \eta', \phi) l\nu \) decay rates in \( 10^{10} \) s\(^{-1} \), \( |V_{cs}| = 0.975 \). The experimental rates are obtained from the corresponding branching ratios using the \( D_s \) lifetime \( \tau_{D_s} = 0.495 \pm 0.013 \) ps from the 1999 update [31].

| Ref | \( \Gamma(D_s \rightarrow \eta) \) | \( \Gamma(D_s \rightarrow \eta') \) | \( \Gamma(D_s \rightarrow \phi) \) |
|---|---|---|---|
| This work | 5.0 | 1.85 | 5.1 |
| Exp [31] | 5.2±1.3 | 2.0±0.8 | 4.04±1.01 |

\(^6\) Another procedure of taking into account the SU(3) breaking effects to obtain \( \Psi_{\eta_s} \) from \( \Psi_{\eta_n} \) has been proposed in [12].
For the coupling constants we obtain
\[ \frac{g_{D_0,D_0} f^{(D_0^*)}_V}{2M_{D_0^*}} = 1.0 \pm 0.1, \quad \frac{g_{D_0,D_F} f^{(D_F)}_V}{2M_{D_F}} = 1.6 \pm 0.3, \quad \frac{f^{(D_0^*)}_V}{f^{(D_F)}_V} = 0.93 \pm 0.03, \quad \frac{g_{D_0,D_0} f^{(D_F)}_V}{g_{D_0,D_0} f^{(D_0^*)}_V} = 1.08 \pm 0.04. \]

3. \( B_s \to K, K^* \)

This mode is driven by the \( b \to u \) charged current transition. The only additional new parameter needed here is the slope of the \( B_s \) wave function. We obtain it by using (3) and taking \( f_{B_2}/f_B = 1.1 \). The results of our calculation are given in Table XXI.

| \( B_s \to K \) | \( B_s \to K^* \) |
|----------------|----------------|
| \( f(0) \)     | 0.31           |
| \( \sigma_1 \) | 0.63           |
| \( \sigma_2 \) | 0.33           |

These form factors lead to the following relations
\[ \frac{g_{B^*B,K} f^{(B^*)}_V}{2M_{B^*}} = 0.44 \pm 0.04, \quad \frac{g_{BB,K} f^{(B)}_V}{2M_{B^*}} = 1.3 \pm 0.1, \quad \frac{f^{(B^*)}_V}{f^{(B)}_V} = 0.95 \pm 0.05, \quad \frac{g_{B^*B,K^*}}{g_{B^*B,K}} = 1.2 \pm 0.1. \]

The form factors at \( q^2 = 0 \) are compared with the LCSR predictions in Table XXII. We observe some disagreement between our predictions and the LCSR calculation which gives smaller values for all the form factors. A closer look at the origin of this discrepancy shows that its source is the strength and sign of the SU(3)-breaking effects. They lead to opposite corrections in the two approaches.

| \( B_s \to K^* \) |
|----------------|
| \( f(0) \)     | 0.38           |
| \( \sigma_1 \) | 0.29           |
| \( \sigma_2 \) | 0.29           |

To discuss these SU(3) breaking effects, let us start with \( B \to \rho \), which in fact differs from the \( B_s \to K^* \) only by the flavour of the spectator quark, and move to \( B_s \to K^* \) by accounting for the SU(3) violating effects:

Within the LCSR method there are two changes which affect the form factors: first, the change \( f_{B_2} \to f_B \) leads to an increase of the \( B_s \to K^* \) form factors; second, the change of the symmetric twist-two distribution amplitude of the \( \rho \)-meson to the asymmetric one of the \( K^* \) meson leads to a decrease of the form factors. The second effect turns out to be much stronger than the first one with the result of an overall decrease of the form factors.

In the quark model, the same SU(3) breaking effects take place: The change of the spectator mass (it determines the increase of \( f_{B_2}/f_B \)) and the change of the \( K^* \) meson wave function (due to the change of both the quark mass and the slope parameter of the light meson wave function). Here the influence of the slope of the heavy meson wave function upon the form factor is only marginal. Therefore, the resulting effect of these changes leads to an increase of the form factors.

We want to point out that the difference between the results of the two approaches does not arise from specific effects (higher twists, higher radiative corrections etc) which are present in the LCSRs but absent in the quark model. The observed difference is only due to the different strength of the SU(3) violating effects at the level of the twist-2 distribution amplitude. As was discussed in [20], this distribution amplitude can be expressed through the radial soft wave function of the meson. The change of the quark-model wave function caused by SU(3) violating effects does not induce a strong asymmetry in the leading twist-2 distribution amplitude.

In view of the discrepancy between our results and the LCSR it would be interesting to have independent calculations of the \( B_s \to K^* \) form factors at small \( q^2 \) from the 3-point sum rules, as well as a lattice calculation for large \( q^2 \).
4. $B_s \to \eta, \eta', \phi$

These weak meson transitions are induced by the FCNC $b \to s$ quark transition. The results of the form factor calculation are given in Table XXIII and compared with the LCSR predictions at $q^2 = 0$ in Table XXIV. The agreement between the two values is satisfactory at least within the declared 15\% accuracy of the LCSR predictions. This allows us to expect that also the $D_s \to \phi, \eta, \eta'$ form factors and the corresponding decay rates (given earlier in subsection 2) are calculated reliably.

TABLE XXIII. The calculated $B_s \to \eta, \phi, \eta'$ transition form factors. $M_V = M_{B_s} = 5.42$ GeV, $M_P = M_{B_s} = 5.37$ GeV. For the form factors $F_1, F_T, V, A_0, A_1$ the fit formula Eq. (9) is used, for the other form factors - Eq. (10).

| $B_s \to \eta_s(M_s)$ | $B_s \to \eta_s(M_{s'})$ | $B_s \to \phi$ |
|----------------------|------------------------|---------------|
| $F_0$                | $F_0$                  | $F_0$         |
| $F_1$                | $F_1$                  | $F_T$         |
| $F_T$                | $V$                    | $A_0$         |
| $A_1$                | $A_2$                  | $T_1$         |
| $A_2$                | $T_2$                  | $T_3$         |

TABLE XXIV. Comparison of the QM and LCSR results on the $B_s \to \phi$ form factors at $q^2 = 0$.

| Ref.      | $V(0)$ | $A_1(0)$ | $A_2(0)$ | $A_0(0)$ | $T_1(0)$ | $T_2(0)$ |
|-----------|--------|----------|----------|----------|----------|----------|
| This work | 0.44   | 0.34     | 0.31     | 0.42     | 0.38     | 0.25     |
| LCSR’98 [11] | 0.433 | 0.296    | 0.255    | 0.382    | 0.35     | 0.25     |

For the coupling constants we obtain

\[
\frac{g_{B_s B_s \eta_s} f_V^{(B_s^*)}}{2M_{B_s^*}} = 0.6 \pm 0.05, \quad \frac{g_{B_s B_s \phi} f_{T_s}^{(B_s^*)}}{2M_{\phi}} = 1.5 \pm 0.1, \quad \frac{f_T^{(B_s^*)}}{f_V^{(B_s^*)}} = 0.95 \pm 0.05, \quad \frac{g_{B_s B_s \phi}}{g_{B_s B_s \eta_s}} = 1.13 \pm 0.06.
\]

IV. CONCLUSION

We have calculated numerous form factors of heavy meson transitions to light mesons which are relevant for the semileptonic (charged current) and penguin (flavor-changing neutral current) decay processes. Our approach is based on evaluating the triangular decay graph within a relativistic quark model which has the correct analytical properties and satisfies all known general requirements of QCD.

The model connects different decay channels in a unique way and gives the form factors for all relevant $q^2$ values. The disadvantage of the constituent quark model connected with its dependence on ill-defined parameters such as the effective constituent quark masses, have been reduced by using several constraints: the quark masses and the slope parameters of the wave functions are chosen such that the calculated form factors reproduce the lattice results for the $B \to \rho$ form factors at large $q^2$ and the observed integrated rates of the semileptonic $D \to K, K^*$ decays.

Our main results are as follows:

- In spite of the rather different masses and properties of mesons involved in weak transitions, all existing data on the form factors, both from theory and experiment, can be understood in our quark picture. Namely, all the form factors are essentially described by the few degrees of freedom of constituent quarks, i.e. their wave functions and their effective masses. Details of the soft wave functions are not crucial; only the spatial extension of these wave functions of order of the confinement scale is important. In other words, only the meson radii are essential.

- The calculated transition form factors are in all cases in good agreement with the results available from lattice QCD and from sum rules in their specific regions of validity. The only exception is a disagreement with the LCSR results for the $B_s \to K^*$ transition where we predict larger form factors. This disagreement is caused by a different way of taking into account the SU(3) violating effects when going from $B \to \rho$ to $B_s \to K^*$ and is not related to specific details of the dynamics of the decay process. We suspect that the LCSR method overestimates the SU(3) breaking in the long-distance region but this problem deserves further clarification.
We have estimated the products of the meson weak and strong coupling constants by using the fit formulas for the form factors for the extrapolation to the meson pole. The error of such estimates connected with the errors in the extrapolation procedure is found to be around 5-10%.

We cannot provide for definite error estimates of our predictions for the form factors because of the approximate character of the constituent quark model. However from the fine agreement obtained in cases where checks are possible, we believe that the actual accuracy of our predictions for the form factors is around 10%. Since some parameters have been fixed by using lattice results and have also been tested using the sum rule predictions, further improvements of the accuracy of our predictions will follow if these approaches attain smaller errors. Of course, each precisely measured decay will also allow a more accurate determination of the parameters of the model and thus can be used to diminish the errors at least for closely related decays.

V. ACKNOWLEDGMENTS

We dedicate this paper to Franz Wegner on the occasion of his 60-th birthday. We are grateful to D. Becirevic, M. Beyer, Th. Feldmann, A. Le Yaouanc, N. Nikitin, O. Pène, and S. Simula for helpful and interesting discussions. One of us (DM) gratefully acknowledges the financial support of the Alexander von Humboldt Stiftung.

VI. APPENDIX: WEAK AND STRONG MESON COUPLING CONSTANTS

We provide here definitions of the coupling constants which determine the behavior of the form factors at \( q^2 \) near the resonance poles (beyond the decay region). We consider as an example the case of the \( B \to \pi, \rho \) transition.

1. Weak decay constants

Weak decay constants of mesons are determined by the following relations

\[
\langle B(q)|\bar{b}(0)\gamma_\mu q(0)|0\rangle = i f^{(B)}_P q_\mu,
\]

\[
\langle B^*(q)|\bar{b}(0)\gamma_\mu q(0)|0\rangle = \epsilon^{(B^*)}_\mu M_B f^{(B^*)}_V,
\]

\[
\langle B^*(q)|\bar{b}(0)\sigma_{\mu\nu} q(0)|0\rangle = i(\epsilon^{(B^*)}_\mu q_\nu - \epsilon^{(B^*)}_\nu q_\mu) f^{(B^*)}_T,
\]

where \( \epsilon^{(B^*)}_\mu \) is the \( B^* \) polarization vector. In the heavy quark limit one has \( f^{(B)}_P = f^{(B^*)}_V = f^{(B^*)}_T \).

2. Strong coupling constants

Strong coupling constants are connected with the three-meson amplitudes as follows

\[
\langle \pi(p_2)B(p_1)|B^*(q)\rangle = \frac{1}{2} g_{B^*B\pi} P_\mu \epsilon^{(B^*)}_\mu,
\]

\[
\langle \rho(p_2)B(p_1)|B^*(q)\rangle = \frac{1}{2} \epsilon_\alpha \epsilon_\beta \epsilon^{(B^*)}_\alpha \epsilon^{(B^*)}_\beta P_\mu q_\nu \frac{g_{B^*B\rho} M_B}{M_B^*},
\]

\[
\langle \rho(p_2)B(p_1)|B^*(q)\rangle = \frac{1}{2} g_{B^*B\rho} P_\mu \epsilon^{(\rho)}_\mu,
\]

where \( q = p_1 - p_2 \), \( P = p_1 + p_2 \) and \( \epsilon_\mu \) is the polarization vector of the vector meson.

In the heavy quark limit \( g_{B^*B\rho} = g_{BB\rho} \).

3. Form factors

The form factors \( F_+, F_T, V, T_1 \) contain pole at \( q^2 = M_{B^*}^2 \) due to the contribution of the intermediate \( B^* (1^-) \) state in the \( q^2 \) channel. The residue of this pole is given in terms of the product of the weak and strong coupling constants such that in the region \( q^2 \approx M_{B^*}^2 \) the form factors read
\[ F_+ = \frac{g_{B^* B \pi} f_{V}^{(B^*)}}{2M_B^*} \frac{1}{1 - q^2/M_B^{2*}} + ..., \]

\[ F_T = \frac{g_{B^* B \pi} f_{T}^{(B^*)}}{2M_B^*} \frac{M_B + M_\pi}{M_B^*} \frac{1}{1 - q^2/M_B^{2*}} + ..., \]

\[ V = \frac{g_{B^* B \rho} f_{V}^{(B^*)}}{2M_B^*} \frac{M_B + M_\rho}{M_B^*} \frac{1}{1 - q^2/M_B^{2*}} + ..., \]

\[ T_1 = \frac{g_{B^* B \rho} f_{T}^{(B^*)}}{2M_B^*} \frac{1}{1 - q^2/M_B^{2*}} + ... \]

(16)

Here \( ... \) stand for the terms non-singular at \( q^2 = M_B^{2*} \).

Similarly, \( A_0 \) contains the contribution of the \( B (0^-) \) state. In the region of \( q^2 \approx M_B^{2*} \) it can be represented as follows:

\[ A_0 = \frac{g_{B B \rho} f_{V}^{(B)}}{2M_B} \frac{M_B}{2M_\rho} \frac{1}{1 - q^2/M_B^{2*}} + ... \]

(17)

First let us notice that the residues of the form factors are not all independent and are connected with each other as follows:

\[ \frac{Res(F_T)Res(V)}{Res(F_+)Res(T_1)} = \frac{M_B + M_\rho}{M_B^*} + \frac{M_B + M_\pi}{M_B^*}. \]

(18)

This relation can be used as a cross-check of the consistency of the extrapolation for the form factors.

The coupling constants are related to the residues of the form factors according to the relations

\[ \frac{g_{B^* B \pi} f_{V}^{(B^*)}}{2M_B^*} = Res(F_+), \quad \frac{g_{B B \rho} f_{V}^{(B)}}{2M_B} = 2Res(A_0), \]

\[ \frac{f_{T}^{(B^*)}}{f_{V}^{(B^*)}} = \frac{Res(F_T)}{Res(F_+)} \frac{M_B^*}{M_B + M_\pi}, \quad \frac{g_{B^* B \rho}}{g_{B^* B \pi}} = \frac{Res(V)}{Res(F_+)} \frac{M_B^*}{M_B + M_\rho}. \]

[32] The rates for the $D \to \pi$ and $D \to \rho$ are obtained by combining the values for the $D \to K$ and $D \to K^*$ with the measurements of the ratios of the branching fractions $D \to \pi/D \to K$ by CLEO [53] and $D \to \rho/D \to K^*$ by E653 [54].
