Abstract

We obtain exact upper and lower bounds on the steady state drift velocity, and kinetic energy of electrons, driven by an external field in a weakly ionized plasma (swarm approximation). The scattering is assumed to be elastic with simplified velocity dependence of the collision cross sections. When the field is large the bounds are close to each other and to the results obtained from the conventional approximation of the Boltzmann equation in which one keeps only the first two terms of a Legendre expansion. The bounds prove rigorously that it is possible to increase the electron mobility by the addition of suitably chosen scatterers to the system as predicted by the Druyvesteyn approximation and found in experiments.

I. Introduction

The behavior of the electron mobility in a gas composed of several species is a subject of continued experimental and theoretical investigations [1-4]. Of particular interest is the fact that the addition of certain types of scatterers, i.e. neutral species, to the gas increases the electron mobility and therefore the electron current in an applied electric field [3,4]. This effect is potentially of practical utility and, as was pointed out by Nagpal and Garscadden [4], can be used to obtain information about scattering cross sections and level structure of different species.

The fact that the mobility can actually increase with the addition of scatterers is at first surprising: it is contrary to the well known Matthiessen rule in metals which states that the total resistivity due to different types of scatterers is the sum of resistivities due
to each of them [5]. A closer inspection shows that Matthiessen’s rule refers to the linear regime of small electric fields while the observations and analysis in gases [3,4] are in the nonlinear high field regime.

This still leaves open the question of the validity of approximations commonly made in calculating the current of weakly ionized plasmas in strong fields. We therefore investigate here rigorously the stationary solutions of the kinetic equation for the electron velocity distribution function in cases where the electron-neutral (e-n) collisions are purely elastic and their cross section is modeled by a simple power dependence on the electron speed. In particular we establish two-sided bounds for the electron mean energy and drift in the presence of an external electric field. These bounds show that the results obtained for the current and energy of the electrons in the usual approximation, which neglects higher order terms in a Legendre polynomial expansion and gives the Druyvesteyn-like distribution for large fields, are qualitatively right and even provide good quantitative answers. In fact they are sufficiently precise to confirm an increase in the current for large (but not for small) fields upon addition of some gases, provided the mass of the added species is smaller than that of the dominant one, e.g. adding Helium to an Xenon gas, and the different cross sections satisfy certain conditions. We believe that our analysis can be extended to include more realistic elastic cross sections and inelastic collisions; these are most important in practice for enhancement of the electron mobility.

II. Kinetic Equation

Our starting point is the commonly used swarm approximation, applicable to gases with a very small degree of ionization, [6-10]. In this approximation only e-n collisions are taken into account in the kinetic equation for the electron distribution function (EDF) \( f(r,v,t) \). The neutrals themselves, which may consist of several species, are assumed to have a Maxwellian distribution with a specified common temperature \( T_n \). Further simplification is achieved if the e-n collisions are assumed to be essentially elastic: the collision integral can then be reduced [1,6] to a differential operator due to the great difference in the masses of the electrons and neutrals. To simplify matters further we consider the case where the scattering is spherically symmetric. The stationary kinetic equation for the normalized EDF, in a spatially uniform system with constant density \( n \) subject to an external electric field \( F \), can then be written in the form [6]

\[
-e \frac{F}{m} \cdot \nabla_v f = \frac{1}{v^2} \frac{\partial}{\partial v} \left[ \frac{\epsilon(v)}{\lambda(v)} \frac{v^4}{\lambda(v)} \left( f_0 + \frac{k T_n}{m v} \frac{\partial f_0}{\partial v} \right) \right] + \frac{v}{\lambda(v)} (f_0 - f),
\]  

(1)

\[
\lambda(v) = \left[ \sum_{i=1}^{S} N_i \sigma_i(v) \right]^{-1}, \quad \epsilon(v) = \lambda(v) m \sum_{i=1}^{S} \frac{N_i \sigma_i(v)}{M_i}.
\]
Here $e, m$ are the electron charge and mass, $\sigma_i$ is the collision cross section with species $i$ whose mass is $M_i$ and number density is $N_i$, $\lambda$ is the mean free path in the e-n collisions, $k$ is Boltzmann’s constant, $f_0$ is the spherically symmetric part of the distribution function,

$$f_0(v) = \frac{1}{4\pi} \int f(v) d\Omega.$$

We note that $\epsilon$ is a small parameter equal to the ratio of the electron mass to the mean mass of neutral scatterers, $\epsilon = m\bar{M}^{-1}$, where $\bar{M}^{-1} = \sum M_i^{-1} N_i \sigma_i / \sum N_i \sigma_i$.

### A. Velocity independent cross sections

We shall consider first the case where $\sigma_i(v)$ is independent of $v$ so $\lambda = \text{const}$ and $\epsilon = \text{const}$. Taking the electric field parallel to the z-axis Eq.(1) can be written in the following dimensionless form

$$-E \frac{\partial f}{\partial u_z} = \epsilon \frac{1}{u^2} \frac{\partial}{\partial u} \left[ u^4 \left( f_0 + T \frac{\partial f_0}{\partial u} \right) \right] + u(f_0 - f),$$

where

$$u = \gamma v, \quad u = \sqrt{u_x^2 + u_y^2 + u_z^2},$$

$$\gamma = \sqrt{\frac{m}{kT_0}}, \quad T = \frac{T_n}{T_0}, \quad E = \frac{e\lambda|\mathbf{F}|}{kT_0}$$

with some fixed $T_0$ specifying the units of the temperature. We normalize $f$ so that

$$\frac{1}{4\pi} \int f(u) d^3u = \int_0^\infty u^2 f_0 du = 1, \quad (3)$$

When $E = 0$ the stationary distribution is the Maxwellian with temperature $T$,

$$f = f_0 = M(u) = \sqrt{\frac{2}{\pi T^3}} \exp \left( -\frac{u^2}{2T} \right), \quad (4)$$

$M(u)$ is the unique solution of (2) for $E = 0$, $\epsilon \neq 0$. When $E \neq 0$ the situation is more complicated. Only for $E$ small compared to $\epsilon$ can we expect the stationary EDF to be close to $M(u)$. But in the physically interesting regimes it is $\epsilon$ which is small compared to $E$. On the other hand if $\epsilon \simeq 0$ the collisions almost do not change the electron energy so it is difficult for the electrons to get rid of the energy they acquire from the field. The limit $\epsilon \to 0$ is therefore singular. In particular there is no well defined reference stationary state for $\epsilon = 0$ about which to expand the solution of (2).

### B. Legendre Expansion
The usual method [8] of solving (2) is to expand \( f(u) \) in terms of the Legendre polynomials \( P_l \),

\[
f(u) = \sum_{l=0}^{\infty} f_l(u) P_l(\cos \theta), \quad f_l(u) = \frac{2l+1}{4\pi} \int f(u) P_l(\cos \theta) d\Omega_u,
\]

(5)

where \( \theta \) is the angle between \( u \) and the field \( \mathbf{F} \): \( \cos \theta = u_z/u \). Substituting (5) into (2) we obtain an infinite set of coupled ordinary differential equations for \( l \geq 0 \), \( u \geq 0 \). These have the form

\[
-\frac{E}{3} \left( \frac{df_1}{du} + \frac{2}{u} f_1 \right) = \epsilon \frac{1}{u^2} \frac{d}{du} \left[ u^4 \left( f_0 + \frac{T df_0}{u du} \right) \right], \quad l = 0,
\]

(6)

and

\[
E \left[ \frac{l}{2l-1} \left( \frac{df_{l-1}}{du} - \frac{l-1}{u} f_{l-1} \right) + \frac{l+1}{2l+3} \left( \frac{df_{l+1}}{du} + \frac{l+2}{u} f_{l+1} \right) \right] = u f_l, \quad l = 1, 2, \ldots
\]

(7)

Eq. (6) can be integrated to give,

\[
f_1 = -\frac{3\epsilon}{E} u^2 \left( f_0 + \frac{T df_0}{u du} \right),
\]

(8)

where the arbitrary constant of integration was taken to be 0, using reasonable assumptions on the behavior of \( f \) as \( u \to 0 \) and \( u \to \infty \).

In the conventional [8-10] approximation scheme only two terms of expansion (5) are kept. This is equivalent to assuming \( f_l(v) \equiv 0 \) for \( l \geq 2 \). One then adds to (8) one more differential equation, obtained from (7), for \( l = 1 \)

\[
E \frac{df_0}{du} = u f_1.
\]

(9a)

Substituting (8) into (9) then yields an equation for \( f_0 \)

\[
\left( 1 + \frac{3\epsilon T}{E^2 u^2} \right) \frac{df_0}{du} + \frac{3\epsilon}{E^2} u^3 f_0 = 0,
\]

(9b)

whose solution is

\[
f_0 = C \exp \left( -\int_0^u \frac{x^3 dx}{T x^2 + E^2/3\epsilon} \right).
\]

(9c)

This \( f_0 \) becomes the Maxwellian \( M(u) \), (4), when \( E = 0 \) and the Druyvesteyn [11] distribution \( f^D \) when \( T = 0 \):

\[
f_0 = f^D = C \exp \left( -\frac{3\epsilon u^4}{4E^2} \right), \quad C = \sqrt{2} \left( \frac{3\epsilon}{E^2} \right)^{3/4} / \Gamma \left( \frac{3}{4} \right),
\]

(10a)

4
where $\Gamma$ is the gamma function. Using (9) and (10a) one can find $f_1$:

\[
 f_1 = -C \frac{3\epsilon u^2}{E} \exp \left( - \frac{3\epsilon u^4}{4E^2} \right). \tag{10b}
\]

For $T > 0$, $f_0$ in (9c) will always have a Maxwellian form for $u >> \left( \frac{E^2}{T \epsilon} \right)^{1/2}$.

The first two harmonics are sufficient to find the mean energy per particle $W$ and mean speed (drift) $w$ of the electrons which are physically the most important properties of the stationary state,

\[
 W = \frac{m}{8\pi} \int v^2 f(v) d^3v = \frac{m}{2\gamma^2} \int_0^\infty u^4 f_0 du, \quad w = \frac{-1}{4\pi\gamma^2} \int u z f d^3u = \frac{-1}{3\gamma} \int_0^\infty u^3 f_1 du. \tag{11}
\]

We shall now study the properties of these moments without the approximations made for explicitly solving Eq.(2).

III. Moments of the Distribution Function

We assume that moments

\[
 M_k^{(l)} = \int_0^\infty u^k f_l(u) du \tag{12}
\]

exist at least for $0 \leq k \leq 9$. Multiplying (7) by a positive power $k$ of $u$ and integrating over $u$ yields the equations

\[
 E \left[ -i \frac{l + k - 1}{2l - 1} M_k^{(l-1)} + \frac{(l + 1)(l + 2 - k)}{2l + 3} M_k^{(l+1)} \right] = M_k^{(l)} + 1, \tag{13}
\]

In terms of these moments $w$ and $W$ can be written, using (11) and (8), as

\[
 w = \frac{\epsilon}{E\gamma} \left[ M_5^{(0)} - 4T M_3^{(0)} \right], \quad W = \frac{m}{2\gamma^2} M_4^{(0)}. \tag{14}
\]

We will now construct estimates of $w$ and $W$ by using (8) and (13) to get relations between the $M_k^{(0)}$.

i) Taking $l = 1$ and $k = 3$ in (13) and substituting (8) for the calculation of $M_4^{(1)}$ gives

\[
 M_2^{(0)} = 1 = \frac{\epsilon}{E^2} (M_6^{(0)} - 5T M_4^{(0)}). \tag{15}
\]

ii) For $l = 1, k = 6$, Eqs. (13) and (8) yield

\[
 M_5^{(0)} + \frac{1}{5} M_5^{(2)} = \frac{\epsilon}{2E^2} (M_9^{(0)} - 8T M_7^{(0)}). \tag{16}
\]
iii) The set \( l = 2, \ k = 4 \) allows us to find \( M^{(2)}_5 \):

\[
M^{(2)}_5 = -\frac{10}{3}EM^{(1)}_3 = 10\epsilon(M^{(0)}_5 - 4TM^{(0)}_3)
\]

and eliminate it from (16) to obtain,

\[
(1 + 2\epsilon)M^{(0)}_5 - 8T\epsilon M^{(0)}_3 = \frac{\epsilon}{2E^2}(M^{(0)}_9 - 8TM^{(0)}_7).
\] (17)

Further calculation using different \( l \) and \( k \) will give additional equations for the \( M^{(0)}_j \) which might improve the estimates, but we shall use here only (15) and (17).

Exploiting now general bounds on moments of the nonnegative density \( f_0(u) \) derived in the Appendix we obtain two-sided bounds for \( M^{(0)}_3, \ M^{(0)}_4, \ M^{(0)}_5 \), which determine, by (14), the electron drift \( w \) and mean energy \( W \).

**Inequalities**

The upper bounds on \( M_j, \ j = 3, 4, 5, \) (we have dropped the superscript zero) can be calculated from (15) using (A5):

\[
M_4 \leq M^{1/2}_6 => 1 \geq \frac{\epsilon}{E^2} (M^2_4 - 5TM_4) => M^2_4 - 5TM_4 - \frac{E^2}{\epsilon} \leq 0.
\]

By solving the last inequality one gets

\[
M_4 \leq a, \ a = \frac{5T}{2} + \sqrt{\frac{E^2}{\epsilon} + \left(\frac{5T}{2}\right)^2}.
\] (18)

The same technique using bounds,

\[
M_3 \leq (M_6)^{1/4}, \ M_5 \leq (M_6)^{3/4}
\]

gives

\[
M_3 \leq a^{1/2}, \ M_5 \leq a^{3/2}, \ M_6 \leq a^2, \ \frac{M_6}{M_4} \geq a.
\] (19)

The derivation of lower bounds via (15) and (17) is more intricate. Keeping in mind that \( \epsilon \) is small, we use (17) in the form of an inequality

\[
\frac{2E^2}{\epsilon} (1 + 2\epsilon) > \frac{M_9}{M_5} - 8T \frac{M_7}{M_5} \geq \sqrt{\frac{M_9}{M_5}} \left(\sqrt{\frac{M_9}{M_5} - 8T}\right),
\]

where we have used \( M_7 \leq \sqrt{M_5M_9} \) in virtue of (A5). Using now (A6) with \( j = 5, \ n = 1, \ s = 4 \) we obtain

\[
\frac{M_9}{M_5} \geq \left(\frac{M_6}{M_5}\right)^4
\]

6
and a quadratic inequality for $M_6/M_5$ whose solution is
\[ \frac{M_6}{M_5} \leq b^{1/2}, \quad b = 4T + \sqrt{(4T)^2 + \frac{2E^2(1 + 2\epsilon)}{\epsilon}} \] (20).

We repeat now in (20) the use of (A6) with $i = 6$, $k = 1$, $s = 2$ and $i = 6$, $k = 2$, $s = 3/2$ with the results
\[ \frac{M_6}{M_4} \leq b, \quad \frac{M_6}{M_3} \leq b^{3/2}. \] (21)

One can solve (15) for $M_6$ in terms of $M_4$ and using (21) obtain the inequality
\[ M_4 = \frac{M_4}{M_6} M_6 = \frac{M_4}{M_6} \left( \frac{E^2}{\epsilon} + 5T M_4 \right) \geq b^{-1} \left( \frac{E^2}{\epsilon} + 5T M_4 \right). \]

Its solution is
\[ \frac{M_4}{M_6} \geq \frac{E^2}{\epsilon(b - 5T)}. \] (22)

Similarly expressing $M_5$ and $M_3$ through $M_5/M_6$ and $M_3/M_6$ respectively and using (15), (20)-(22) we find the lower bounds. Together with (19) they allow us to write down two-sided bounds for $M_j$, $(j = 3, 4, 5)$ in the form
\[ a j^{-1/2} \geq M_j \geq b j^{-2-2} \frac{E^2}{\epsilon(b - 5T)}. \] (23)

These are sufficient, by (14), for the estimation of $w$ and $W$. One can write immediately
\[ \frac{ma}{2\gamma^2} \geq W \geq \frac{mE^2}{2\gamma^2\epsilon(b - 5T)}. \] (24a)

Using the definition (14) and the inequality (A5) we obtain
\[ \frac{\epsilon}{E\gamma} M_5 \geq w \geq \frac{\epsilon}{E\gamma} M_5^{1/3} (M_5^{2/3} - 4T), \] (24b)

which can be combined with (23) for $j = 5$ to get explicit bounds on $w$.

The lower bounds in (23) are useless when $E \rightarrow 0$ and the solution of (2) approaches the Maxwellian. Generally, the inequalities (23) become more useful the larger $E$ is.

IV. Comparison with the Druyvesteyn Approximation

When the background temperature $T$ is small compared with $E\epsilon^{-1/2}$ it can be neglected in (18),(20) and the bounds (24) look simpler:
\[ \frac{\epsilon^{1/4}\sqrt{E}}{\gamma} \geq w \geq \frac{\epsilon^{1/4}\sqrt{E}}{\gamma[2(1 + 2\epsilon)]^{1/4}}, \quad \frac{mE}{2\gamma^2\sqrt{\epsilon}} \geq W \geq \frac{mE}{2\gamma^2\sqrt{2\epsilon(1 + 2\epsilon)}}. \] (25)
These bounds specify the electron drift and mean energy as functions of the electric field and gas parameters within errors of about ±20% for the mean energy and ±8% for the drift uniformly in $E$ and $\epsilon$. For comparison $w$ and $W$ obtained from the Druyvesteyn distribution [10a] are

$$w \approx 0.897 \frac{E^{1/2}}{\gamma}, \quad W \approx 0.854 \frac{mE}{2\gamma^2 \sqrt{\epsilon}}$$

in good agreement with (25) when $\epsilon << 1$.

Experimentalists also measure sometimes the transversal $D_t$ and longitudinal $D_L$ diffusion constants for the electron swarm. While $D_L$ cannot generally be expressed [2,9] in terms of the velocity moments,

$$D_t = D = \frac{\bar{\lambda}}{3\gamma} M_3$$

is just the isotropic diffusion constant, where $\bar{\lambda}$ is the mean free path of electrons ($\bar{\lambda} = \lambda$ here). When $T$ can be neglected we obtain

$$\frac{\lambda}{3\gamma} \left[ \frac{E^2}{\epsilon} \right]^{1/4} \geq D \geq [2(1 + 2\epsilon)]^{-3/4} \frac{\lambda}{3\gamma} \left[ \frac{E^2}{\epsilon} \right]^{1/4}$$

(27).

For comparison

$$D \approx 0.759 \frac{\lambda}{3\gamma} \left( \frac{E^2}{\epsilon} \right)^{1/4}$$

in the Druyvesteyn approximation.

**V. Mobility in Binary Mixtures**

The increase of electron mobility $w/F$ in a plasma upon the addition of a small amount of a new gas has been observed in [3]. It was calculated in [4] within the two-term approximation (8), (9) for binary mixtures of a heavy noble Ramsauer gas and Helium addition. We shall show here rigorously that this effect exists even with constant collision cross sections. Using (11) gives

$$w = -\frac{1}{3\gamma} M^{(1)}_3$$

(28)

and for $l = 1$ Eq.(13) reads

$$M^{(1)}_{k+1} = E \left( -k M^{(0)}_{k-1} + \frac{3-k}{5} M^{(2)}_{k-1} \right).$$

(29)
When $E \to 0$ we may neglect the second term in (29) and obtain

$$w \approx \frac{2E}{3\gamma}M_1^{(0)} \approx \frac{4E}{3\gamma\sqrt{2\pi T}} = \frac{2}{3} \sqrt{\frac{2}{\pi}} \frac{eF\lambda}{\sqrt{mkT}},$$

(30)

using (4) and the initial notation. The resistivity $F/enw$ is here proportional to $\sum N_i\sigma_i$, which is just Matthiessen’s rule.

Let us consider now the case of a strong field, $kT_0 << eF\lambda/\sqrt{\epsilon}$, for a binary mixture $i = 1, 2$ and use the two-term ansatz (8), (9). We then have the Druyvesteyn distribution (10) with the moments (26). Using (14) and the notation

$$\alpha = \frac{N_2}{N_1+N_2}, \quad \mu = \frac{M_1}{M_2}, \quad \theta = \frac{\sigma_2}{\sigma_1},$$

we can write explicit expressions for the drift and mean electron energy

$$w = 0.897\sqrt{\frac{eF}{(N_1+N_2)^2\sigma_1\sqrt{mM_1}}} (1-\alpha+\alpha\theta\mu)^{1/4},$$

(31)

$$W = 0.427\frac{eF}{(N_1+N_2)^2}\sqrt{\frac{M_1}{m}}[(1-\alpha+\alpha\theta)(1-\alpha+\alpha\theta\mu)]^{-1/4}. (32)$$

Both the current and energy of electrons increase, but the mobility $w/F$ decreases, as the field $F$ increases.

Let us now keep the total gas density $N_1 + N_2$ constant and vary the relative concentration of components by changing $\alpha$. A simple analysis of (31) shows that $w$ can be non-monotone when both $\theta$ and $\mu$ are larger than 1. For example, if $\theta = 5$, $\mu = 20$ then considering $w$ as a function of $\alpha$, $w = w(\alpha)$, we have

$$\frac{w(\alpha_m)}{w(0)} \approx 1.41, \quad \frac{w(1)}{w(0)} \approx 0.95$$

Here $w(\alpha_m)$ is the maximum value of $w$ obtained for $\alpha_m \approx 0.11$. The drift speed is almost the same in the pure species 1 and 2, but it is noticeably larger in a mixture. The mean energy of electrons changes more: when the lighter component substitutes for the heavier one it goes down:

$$\frac{W(\alpha_m)}{W(0)} \approx 0.46, \quad \frac{W(1)}{W(0)} \approx 0.21.$$  

There is even a more striking situation, when one just adds the lighter gas keeping the density $N_1$ of the heavier component constant. In this case

$$w(\delta) \sim \frac{(1+\delta\theta\mu)^{1/4}}{(1+\delta\theta)^{3/4}}, \quad W(\delta) \sim (1+\delta)^{-1/2}(1+\delta\theta)^{-1/4}(1+\delta\theta\mu)^{-1/4},$$

(33)
where $\delta = N_2/N_1$. Increasing $\delta$ we increase the density of scatterers, but for $\delta = \delta_m = 8.5\%$

$$\frac{w(\delta_m)}{w(0)} \approx 1.4,$$

while the electron energy decreases: $W(\delta_m) \approx 0.5W(0)$.

We obtained these results approximately - by truncating the series (5). However comparing (26) with the bounds (24) we see that the drift velocity and mean energy for the Druyvesteyn approximation cannot differ from the exact solution by more than about $+12, -6\%$ and $\pm 17\%$ respectively. Hence the non-monotone dependence of the electron mobility on the density of the light species holds for the exact solution of the kinetic equation (2). When we had $w_{\text{max}} \approx 1.40w(0)$ (within the approximation) a possible exaggeration of $w_{\text{max}}$ by 12% and underestimation of $w(0)$ at most in 6% could reduce their ratio from 1.40 to 1.16 but the effect is clearly there without approximations.

The explanation of such unusual behavior of the electron drift in the nonlinear regime is quite simple. When $M_2 < M_1$ the addition of species 2 makes the energy transfer from the electrons to atoms easier in the elastic collisions. Consequently the mean electron energy $W$ will drop leading to a net increase of the mean free time $\tau(v) \sim \lambda/v$. The competition of $\lambda$ and $v$ is shown by formulas (31) and (33) where $\alpha, \delta$ represent the concentration of the lighter species and $\mu$ is proportional to its relative effectiveness in the energy transfer. Adding about 10% of a component with atoms of mass $m_2 \sim 0.05m_1$ the mean electron energy decreases by about 1/2 implying the increase of $w$ by about 40%.

This rise of the electron mobility can be stronger [4] in the case when the collision cross section of the main (heavy) component is energy dependent and decreases with the electron energy.

VI. Simple velocity dependent collision cross sections

We consider here a one-species plasma with the atoms of mass $M$ and generalize the bounds (24) for e-n collision cross section of the form

$$\sigma(v) = \sigma_0 \left( \frac{v}{v_0} \right)^p,$$

where the exponent $p$ can be positive or negative in a certain range. Setting

$$v_0^2 = \frac{eF}{mN\sigma_0}, \quad t = \epsilon^{1/2} \frac{kT_n}{mv_0^2}, \quad \epsilon = \frac{m}{M},$$

we can rewrite (1) as

$$-\epsilon^\frac{p+2}{2} \frac{\partial f}{\partial y_z} = \epsilon \frac{1}{y^2} \frac{d}{dy} \left[ y^{p+4} \left( f_0 + \frac{t}{y} \frac{df_0}{dy} \right) \right] + y^{p+1} (f_0 - f),$$

(35)
where \( v = \epsilon^{-1/4} v_0 y \) and we have in mind situations with “strong” electric field \( t << 1 \). Using the Legendre series expansion (5) for \( f(y) \) we again obtain the infinite set of coupled equations for harmonics \( f_l(y) \)

\[
\epsilon^{-\frac{p+2}{4}} y^{1+p} f_l = \frac{l}{2l+1} \left( \frac{df_{l-1}}{dy} - \frac{l-1}{y} f_{l-1} \right) + \frac{l+1}{2l+3} \left( \frac{df_{l+1}}{dy} + \frac{l+2}{y} f_{l+1} \right)
\]

(36)

for \( l = 1, 2, 3, \ldots \) and one more equation

\[
f_1 = -3 \epsilon^{-1/4} y^{p+2} \left( f_0 + \frac{t}{y} \frac{df_0}{dy} \right),
\]

(37)
corresponding to (8).

Methods similar to those in the Section 2 allow us to derive the pair of equations for moments, which generalize (16) and (17):

\[
\mathcal{M}(2p+6) = \epsilon^{p/2} \mathcal{M}(2), \quad \mathcal{M}(3p+9) = \epsilon^{p/2} c \mathcal{M}(p+5),
\]

(38)

where

\[
c = \frac{1}{3} [p + 6 + 4 \epsilon(p + 3)], \quad \mathcal{M}(k) = \int_0^\infty f_0(y) y^k dy
\]

and the background temperature parameter \( t \) is neglected for simplicity. In terms of these moments, which clearly satisfy (A2), we have for the electron drift and mean energy

\[
w = \epsilon^{\frac{1-p}{4}} v_0 \mathcal{M}(p+5), \quad W = \epsilon^{-1/2} \frac{m v_0^2}{2} \mathcal{M}(4).
\]

(39)

A calculation similar to that described in Section 2 and Appendix shows that Eqs(38),(39) yield the following upper (U) and lower (L) bounds for for \( w \) and \( W \):

\[
w_L \leq w \leq w_U, \quad W_L \leq W \leq W_U,
\]

\[
w_L = v_0 \left( \frac{\epsilon}{c} \right)^{\frac{p+4}{2p+4}}, \quad w_U = v_0 \epsilon^{\frac{p+1}{2p+4}}, \quad W_L = \frac{m v_0^2}{2} e^{-\frac{1}{p+2} c^{\frac{p+1}{p+2}}}, \quad W_U = \frac{m v_0^2}{2} e^{-\frac{1}{p+2}},
\]

(40)

which give (24) for the velocity independent cross section \( p = 0 \) when \( T << \epsilon^{-1/2} E \).

We can find the approximate solution of (35)

\[
f_0^D(y) = C \exp \left[ -3 \int_0^y \frac{x^{2p+3} dx}{\epsilon^{p/2} + 3 t x^{2+2p}} \right],
\]

(41)

using the two-term ansatz which leads to the Druyvesteyn function (9c) for \( p = 0 \). Computing the moments in (39) with the help of (41) yields the explicit formulas

\[
w_D = \epsilon^{\frac{p+4}{2p+4}} v_0 \left[ \frac{2p+4}{3} \right]^{\frac{p+3}{2p+4}} \Gamma \left( \frac{p+6}{2p+4} \right) / \Gamma \left( \frac{3}{2p+4} \right),
\]

\[
11
\]
\[ W_D = \epsilon^{\frac{1}{p+2}} \frac{mv_0^2}{2} \left[ \frac{2p + 4}{3} \right]^{\frac{1}{p+2}} \Gamma \left( \frac{5}{2p + 4} \right) / \Gamma \left( \frac{3}{2p + 4} \right). \] (42)

The bounds in (40) for the drift and energy as functions of the parameter \( p \) are shown in Fig.1 in the form \( w_B/w_D - 1, W_B/W_D - 1 \) respectively with the Druyvesteyn result (42) for comparison (we use the subscript "B" for both "L" and "U"). The accuracy of two-term approximation for our models is quite good.

**Appendix**

The moments \( \mathcal{M}_k \) involved in (15), (17)-(24) are the integrals of the non-negative function \( f_0(u) \):

\[ f_0(u) = \frac{1}{2} \int_0^\pi f(u) \sin \theta d\theta. \]

We can easily show that \( \ln \mathcal{M}(k) \) is a concave function if one treats \( k \) as a continuous variable:

\[ \frac{d^2}{dk^2} \ln \mathcal{M} \geq 0. \] (A1)

(A1) is equivalent to the inequality

\[ \mathcal{M} \frac{d^2 \mathcal{M}}{dk^2} \geq \left( \frac{d\mathcal{M}}{dk} \right)^2, \] (A2)

which can be written using (12) as

\[ \int_0^\infty x^k f_0(x)dx \cdot \int_0^\infty y^k \ln^2(y) f_0(y)dy - \left( \int_0^\infty x^k \ln x f_0(x)dx \right)^2 = \]

\[ \frac{1}{2} \int_0^\infty \int_0^\infty x^k y^k \ln^2 \left( \frac{x}{y} \right) f_0(x) f_0(y) dxdy \geq 0. \]

The concavity implies obviously

\[ \frac{\ln \mathcal{M}_k - \ln \mathcal{M}_i}{k - i} \leq \frac{\ln \mathcal{M}_n - \ln \mathcal{M}_m}{n - m}, \quad k > i \geq 0, \quad n > m \geq i, \quad n \geq k. \] (A3)

Taking \( k - i = n - m, \ n - k = j \) we obtain

\[ \frac{\mathcal{M}_k}{\mathcal{M}_i} \leq \frac{\mathcal{M}_{k+j}}{\mathcal{M}_{i+j}}, \quad k > i, \quad j > 0. \] (A4)
For the case $k = m$ (A3) yields inequality

\[(\mathcal{M}_k)^{j-i} \leq (\mathcal{M}_i)^{j-k}(\mathcal{M}_j)^{k-i}, \quad 0 \leq i < k < j,\]  \hspace{1cm} (A5)

which is equivalent to the following useful set:

\[\left(\frac{\mathcal{M}_{j+n}}{\mathcal{M}_j}\right)^s \leq \frac{\mathcal{M}_{j+sn}}{\mathcal{M}_j}, \quad \left(\frac{\mathcal{M}_i}{\mathcal{M}_{i-k}}\right)^s \geq \frac{\mathcal{M}_i}{\mathcal{M}_{i-sk}},\]  \hspace{1cm} (A6)

where $i, j, n, k \geq 0$, $s \geq 1$ and $i \geq sk$.
