Abstract. Inflammation serves an important role in the progression of osteoarthritis (OA), and IL-1β may act as a catabolic factor on cartilage, reducing the synthesis of primary cartilage components type II collagen and aggrecan. Aquaporin 1 (AQP1) is a 28-kDa water channel formed of six transmembrane domains on the cell membrane. AQP1 is highly expressed in the anus, gallbladder and liver, and is moderately expressed in the hippocampus, ependymal cells of the central nervous system and articular cartilage. It was hypothesized that AQP1 may be highly expressed in OA cartilage and that it may increase the expression of catabolic factors during inflammatory OA progression. Therefore, the present study evaluated AQP1 functions in human OA articular chondrocytes. Primary chondrocytes were isolated from human hip and knee cartilage tissues, cultured and transfected with AQP1-specific small interfering RNA with or without subsequent IL-1β treatment. In vitro explant culture from hip cartilages were also prepared. Reverse transcription-polymerase chain reaction (RT-PCR) was performed to assess the expression of AQP genes in human articular cartilage, AQP1 immunohistochemistry of the cartilages and explant culture, as well as RT-quantitative PCR, western blotting and immunocytochemistry/immunofluorescence of OA chondrocytes to evaluate the expression of AQP1, and catabolic and anabolic factors. RT-PCR results demonstrated that AQP0, 1, 3, 7, 9, and 11 were expressed in OA chondrocytes. Immunohistochemistry revealed that AQP1 was highly expressed in the superficial to middle zones of OA articular cartilages. Additionally, AQP1 mRNA was significantly higher in OA cartilage and IL-1β treatment significantly increased AQP1 expression in hip explant cartilage. Furthermore, AQP1 downregulation decreased a disintegrin and metalloprotease with thrombospondin motifs (ADAMTS)-4 expression in OA chondrocytes, though it did not affect other associated genes. Immunofluorescence showed that AQP1 and ADAMTS-4 were co-localized. These findings indicated that AQP1 depletion may decrease ADAMTS-4 expression in human OA chondrocytes. Therefore, regulating AQP1 expression may be a strategy to suppress catabolic factors during OA progression.

Introduction

Osteoarthritis (OA) is the most frequently diagnosed musculoskeletal disorder. It is a multifactorial and slowly progressing degenerative joint disease (1). The role of inflammation in OA progression has been previously reported (2-5). IL-1β is an important cytokine in OA progression by acting as a catabolic factor to reduce the synthesis of two primary cartilage components, the type II collagen (COL2A1) and aggrecan (ACAN) (6). Moreover, the level of IL-1β in the synovial fluid, synovial membrane, cartilage, and subchondral bone layer is elevated in patients with OA (7). Previous reports demonstrated that treatment with IL-1β decreases COL2A1 expression (6) and increases MMP-13 expression (8). Therefore, IL-1β plays a critical role during OA progression.

In mammals, the aquaporin (AQP) family consists of thirteen subtypes (AQP0 to 12) and these proteins are expressed in various tissues (9). AQP expression has been previously reported in several animal models. A previous study demonstrated the expression of AQP1 and AQP3 in normal equine articular chondrocytes (10). Another study showed that AQP1, AQP3, and AQP6 were expressed in rat mandibular condylar cartilage, although only AQP3 mRNA was highly upregulated in rat OA cartilage (11). Additionally, an increase in AQP1 expression in meniscus tissue was demonstrated in an experimentally-induced rat OA model (12).

AQP1 is a membrane protein found in the red blood cells (13). It is a 28-kDa water channel formed by six transmembrane domains with N- and C-termini at the inner cytosolic site of the cell membrane (14). AQP1 is highly expressed in the anus, gallbladder, and liver, and it is moderately expressed in the hippocampus and ependymal cells of the central nervous system and articular cartilage. It was moderately expressed in the hippocampus, ependymal cells of the central nervous system and articular cartilage. Therefore, regulating AQP1 expression may be a strategy to suppress catabolic factors during OA progression.

Key words: aquaporin 1, osteoarthritis, ADAMTS-4, chondrocyte, articular cartilage

ADAMTS PerkinElmer, Inc., Foster City, CA, USA). The expression of the genes of interest was assessed by reverse transcription-polymerase chain reaction (RT-PCR). We confirmed that type II collagen was expressed in normal joints, but the expression was upregulated in the inflamed synovium (20). Here, functional analysis was not performed in these previous studies (15,20-23). We hypothesized that AQP1 is highly expressed in OA cartilages, and AQP1 may increase the expression of catabolic factors. Thus, we evaluated AQP1 functions in human OA chondrocytes.

Materials and methods

Human cartilage samples. OA cartilage tissues were obtained from the cartilage of lateral femoral condyles of patients with end-stage varus-type OA during total knee arthroplasty surgery (n=31). The diagnosis of OA was based on clinical, laboratory, and radiographic evaluations. These patients showed apparent macroscopic OA progression. As a control, normal chondrocytes (as determined macroscopically) were obtained from the hip cartilage of patients that underwent surgery for femoral neck fracture with no recorded tumor complication (n=12). All primary cartilage samples were obtained in accordance with the World Medical Association Declaration of Helsinki (-4). We have used OA chondrocytes isolated from the knee cartilage tissues and cultured. Previously, Macaluso et al (15) showed that the expression of AQP1 is restricted to the choroid plexus (16), but it is expressed in the microvascular endothelia and reactive astrocytes of brain tumors where it is thought to play a role in the development of vasogenic edema (17). Recently, enhanced AQP1 expression was observed in several diseases (18-20). AQP1 expression is increased in patients with autoimmune and alcoholic pancreatitis (18), Alzheimer’s disease (19), and rheumatoid and psoriatic arthritis (20).

Several studies have demonstrated the expression of AQP1 and AQP3 in human articular cartilage (15,20-23). Mobasheri et al (15) showed that AQP1 expression in chondrocytes residing in the deep zone of the articular cartilage, adjacent to the subchondral bone in normal human femoral head articular cartilage. They also reported AQP1 expression in the synovial microvessels and synoviocytes in normal joint, but the expression was upregulated in the inflamed synovium of patients with RA, suggesting that edema formation and synovial fluid accumulation in RA joints may be a consequence of elevated AQP1 expression in the synovium (20). However, functional analysis was not performed in these previous studies (15,20-23). We hypothesized that AQP1 is highly expressed in OA cartilages, and AQP1 may increase the expression of catabolic factors. Thus, we evaluated AQP1 functions in human OA chondrocytes.

RNA isolation and RT-PCR. To evaluate the expression of different AQP genes, OA chondrocytes (n=4) were cultured in 6-well plates with DMEM for 12 h, and RNA was extracted using the QIA shredder and RNeasy Mini kit (Qiagen, Hilden, Germany) according to the manufacturer’s instructions. For RT-PCR, 1 µg of total RNA was reverse transcribed to first-strand complementary DNA (cDNA) using 1.25 µM oligo-dT primers in 40 µl PCR buffer II containing 2.5 mM MgCl2, 0.5 mM dNTP mix, 0.5 U RNase inhibitor, and 1.25 U MuLV reverse transcriptase (PerkinElmer, Inc., Foster City, CA, USA) at 42˚C for 60 min. The cDNA amplification was performed under the following PCR conditions: 94˚C for 5 min; followed by 35 cycles of 94˚C for 30 sec, 55˚C for 30 sec, and 72˚C for 30 sec; and a final extension at 72˚C for 2 min using AmpliTaq Gold DNA Polymerase (cat. no. N8080241; Thermo Fisher Scientific, Inc., Rockford, IL, USA) and specific primers (Table I). The amplicons, along with the TrackIt 50 bp DNA ladder (cat. no. 10488-043; Thermo Fisher Scientific, Inc.), were resolved using 3% polyacrylamide gel electrophoresis, and the signals were visualized using the LAS-3000 mini system (FujiFilm, Tokyo, Japan).

RT-quantitative PCR (RT-qPCR). The relative mRNA levels of human AQP1, matrix metalloproteinase (MMP)-3, MMP-13, a disintegrin and metalloprotease with thrombospondin motifs (ADAMTS)-4, ADAMTS-5, COL2A1, and ACAN in OA chondrocytes (n=19) and normal hip chondrocytes (n=4) were analyzed by SYBR-Green real-time PCR using the ABI prism 7500 sequence-detection system (Applied Biosystems, Foster City, CA, USA). The expression of the genes of interest was normalized against that of the GAPDH housekeeping gene using the comparative quantification cycle (Cq)-value method. The difference between the mean Cq values of the gene of interest and those of the housekeeping gene was denoted as ΔCq, and the difference between the ΔCq of unknown samples and that of the calibrated sample was denoted as ΔΔCq. The relative value of gene expression was calculated as the 2^−ΔΔCq (27). Sequences of the primers used for detection are listed in Table I.

Histological evaluation of cartilage degeneration. The femoral condyles (n=5) and femoral head (n=5) were fixed in 4% paraformaldehyde for 24 h, dehydrated in graded
alcohol solutions, decalcified with 14% EDTA for 7 days, and embedded in paraffin wax. Histological sections were obtained at 10-µm intervals.

**Immunohistochemistry.** Deparaffinized sections were digested with proteinase (Dako, Glostrup, Denmark) for 10 min and treated with 3% hydrogen peroxide (Wako Pure Chemical, Ltd., Industries, Osaka, Japan) to block endogenous peroxidase activity. The sections were treated with a 1:50 dilution of anti-AQP1 antibody (Santa Cruz Biotechnology, Inc., Dallas, TX, USA) at 4˚C overnight, and subsequently treated with peroxidase-labeled anti-mouse immunoglobulin (Histofine Simple Stain MAX PO; Nichirei Bioscience, Tokyo, Japan) at room temperature for 30 min. The signal was developed as brown-reaction products using a peroxidase substrate 3,3’-diaminobenzidine (Histofine Simple Stain DAB solution; Nichirei Bioscience), and the sections were examined under a microscope. Hematoxylin stain was used as a counter stain. Numbers of AQP1-positive cells were counted in five areas of high-magnification fields at both the superficial and deep zones of the cartilage tissue by triple-blinded observers. The average percentage of AQP1-positive cells from the total cell count was calculated. Positive cells superior of the tidemark were included in the assessment.

**Explant culture.** Normal hip cartilages (n=3) were harvested under sterile conditions and explant pieces were placed in a culture dish containing DMEM with or without IL-1β. Forty-eight h after stimulation, the explants were fixed in 4% paraformaldehyde for 24 h, decalcified with 14% EDTA for 7 days, dehydrated in graded alcohol solutions, and embedded in paraffin wax. Histological sections were obtained at 10-µm intervals.

**IL-1β stimulation.** Chondrocytes were cultured in 6-well plates with or without stimulation with 10 ng/ml recombinant human IL-1β/IL-1F2 (cat. no. 201-LB; R&D Systems) for 12 h.

**Small interfering RNA (siRNA) transfection.** OA chondrocytes (n=7) were placed onto 6-well plates at a density of 2.0x10⁶ cells/well in DMEM supplemented with 10% FBS and 100 U/ml of penicillin-streptomycin. After subculturing at 37°C for 24 h under 5% CO₂, the medium was replaced with fresh serum-free medium, and chondrocytes were transfected with 0.5 nM of non-specific control siRNA (negative control no. 2 siRNA; cat. no. AM4613; Thermo Fisher Scientific, Inc.) or AQP1-specific siRNA (cat. no. 4390824, assay ID: s1515 or s1516) using the Lipofectamine RNAiMAX transfection reagent (cat. no. 13778150) (both from Invitrogen; Thermo Fisher Scientific, Inc.).

### Table I. Sequence of primers used in reverse transcription- and reverse transcription-quantitative polymerase chain reaction.

| Gene   | Forward | Reverse |

AQP, aquaporin; MMP, matrix metalloproteinase; ADAMTS, a disintegrin and metalloprotease with thrombospondin motifs; COL2A1, cartilage components type II collagen; ACAN, aggrecan.
Fisher Scientific, Inc., Waltham, MA, USA). Twelve hours after transfection, the cells were treated with IL-1β.

Western blot analysis. OA chondrocytes (n=3) were lysed in a buffer containing 25 mM Tris, 1% Nonidet P-40, 150 mM NaCl, 1.5 mM EDTA, and a protease/phosphatase inhibitor mix (Roche Diagnostics, Basel, Switzerland). The lysates were centrifuged to remove cellular debris. The supernatants were collected, mixed with 4X electrophoresis sample buffer, electrophoresed on a 7.5-15% polyacrylamide gradient gel (Biocraft, Tokyo, Japan), and transferred onto a blotting membrane (GE Healthcare Life Sciences, Little Chalfont, UK). Membranes were incubated with antibodies against AQP1 or α-tubulin (cat. no. T9026; Sigma-Aldrich). Horseradish peroxidase (HRP)-conjugated goat anti-mouse immunoglobulin G antibody (IgG Ab) was used as a secondary antibody and proteins were visualized using the ECL plus reagent (GE Healthcare Life Sciences) in a Chemilumino Analyzer LAS-3000 mini (Fujifilm). Protein expression was determined by semi-quantification of digitally captured images using the NIH ImageJ software (http://imagej.nih.gov/ij/). Three different samples were analyzed.

Immunocytochemistry/immunofluorescence (ICC/IF). OA chondrocytes (n=3) were placed onto a glass-based dish (Iwaki, Tokyo, Japan) at a density of 2.0x10⁵ cells/well in DMEM. Chondrocytes were transfected with non-specific control (0.5 nM) (Qiagen) or AQP1-specific siRNA-1 (0.5 nM) using the Lipofectamine RNAiMAX transfection reagent. Twelve hours after transfection, the cells were left untreated or stimulated with 10 ng/ml of recombinant human IL-1β/IL-1F2 (R&D Systems) for 12 h. After stimulation, the chondrocytes were fixed with 4% paraformaldehyde at room temperature for 30 min and permeabilized with 0.25% Triton X-100 (Nacalai Tesque, Kyoto, Japan) for 30 min. Fixed chondrocytes were then incubated with human anti-AQP1 mouse monoclonal antibody (1:50 dilution; Santa Cruz Biotechnology, Inc.) and mouse anti-ADAMTS-4 rabbit polyclonal antibody (1:500 dilution; Thermo Fisher Scientific, Inc.) in Can Get Signal immunostain Solution A (Toyobo, Osaka, Japan) overnight at 4°C. After the primary antibody incubation, the chondrocytes were incubated with goat anti-mouse immunoglobulin Alexa Fluor Plus 555 (1:200 dilution) and goat anti-rabbit immunoglobulin Alexa Fluor Plus 488 (1:200 dilution) (both from Thermo Fisher Scientific, Inc.) as the secondary antibodies for 60 min at room temperature. The nuclei were stained with DAPI (Nacalai Tesque), and images were viewed and captured using a BZ-X700 microscope (Keyence, Osaka, Japan). Numbers of AQP1-positive cells, ADAMTS-4-positive cells, and DAPI-stained nuclei were counted in four areas of high-magnification fields by triple-blinded observers. The average percentage of AQP1-positive cells and ADAMTS-4-positive cells from the total nuclei count was calculated.

Statistical analysis. The Mann-Whitney U test for comparisons between two groups and one-way analysis of variance with Tukey-Kramer’s post hoc test were applied to analyze differences between time points or between culture conditions. P-values <0.05 indicated statistically significant differences. Results are presented as mean values ± standard error (SE) with 95% confidence intervals (CI). Data analysis was performed using the Bell Curve for Excel software (Social Survey Research Information Co., Ltd., Tokyo, Japan).

Results

AQP1 was highly expressed in human OA chondrocytes. The expression of various AQP genes was examined in OA chondrocytes from four patients with knee OA. Representative electrophoresis results with PCR products showed that AQP0, 1, 3, 7, 9 and 11 were expressed in OA chondrocytes (Fig. 1A). The average AQP1 mRNA expression in OA chondrocytes was significantly higher than that in normal chondrocytes from hip cartilage of four individuals (P=0.014) (Fig. 1B). Immunohistochemistry results showed that surface layer of the articular cartilage was clearly degenerated in the OA group compared to that in the normal hip cartilage group. AQP1 was expressed in the superficial to middle layers in both OA (n=5) and hip (n=5) cartilage tissues (Fig. 2A), and the percentage of AQP1-positive cells was significantly higher in OA cartilages than in normal hip cartilages (AQP1-positive cell percentage: OA, 33.5%; normal hip, 13.4%; P=0.046) (Fig. 2B). Furthermore, AQP1 was expressed in the superficial layers in hip explant cartilages with or without IL-1β treatment (Fig. 2C). The percentage of AQP1-positive cells was significantly higher in explant cartilages treated with IL-1β than in those without IL-1β (AQP1-positive cell percentage: With IL-1β, 26.9%; without IL-1β, 8.2%; P=0.0209) (Fig. 2D). Together, these results indicated that AQP1 was highly expressed in human OA cartilage.
chondrocytes, and the expression levels were increased in response to IL-1β.

**IL-1β increased the expression of AQP1 and catabolic factors in OA chondrocytes.** RT-qPCR analysis showed that the level of AQP1 mRNA was significantly higher in OA chondrocytes treated with 10 ng/ml IL-1β than in untreated chondrocytes. At 4 h after IL-1β stimulation, the level of AQP1 mRNA was 5-fold higher than that of the control (0 h; not treated with IL-1β) (Fig. 3A). The mRNA levels of MMP-3, MMP-13, ADAMTS-4, and ADAMTS-5 were increased significantly following treatment with 10 ng/ml of IL-1β (Fig. 3B-E). The mRNA levels of MMP-3 and MMP-13 were increased in a time-dependent manner until 24 h after stimulation (Fig. 3B and C). The level of ADAMTS-4 mRNA was increased at 12 h after stimulation, but it decreased at 24 h after stimulation (Fig. 3D). The level of ADAMTS-5 mRNA was increased at 12 and 24 h after stimulation (Fig. 3E). In contrast, the levels of COL2A1 and ACAN mRNAs were significantly decreased at 12 and 24 h after stimulation (Fig. 3F and G). These results indicated that IL-1β stimulation increased the expression of AQP1 and catabolic factors, but decreased the expression of anabolic factors in OA chondrocytes. It is important to note that although AQP1 mRNA expression peaked 4 h after IL-1β treatment, the level was still significantly higher than that of the control at 12 h after treatment. At 12 h post-IL-1β treatment, we also observed the peak of ADAMTS-4 and ADAMTS-5 mRNA expression, while that of COL2A1 and ACAN decreased. Thus, we investigated changes in mRNA expression at 12 h after stimulation in subsequent experiments.

**Downregulation of AQP1 decreased ADAMTS-4 expression in OA chondrocytes.** To investigate the functions of AQP1 in chondrocytes, two AQP1-specific siRNAs were used to transfect the OA chondrocytes with or without IL-1β stimulation. IL-1β stimulation significantly increased the level of AQP1 mRNA in OA chondrocytes (Fig. 4A). However, the level of AQP1 mRNA was significantly decreased in chondrocytes transfected with AQP1-specific siRNAs (Fig. 4A). The knockdown efficiency of AQP1 using AQP1 siRNA-1 (s1515) and -2 (s1516) with IL-1β stimulation was 94.3 and 88.5%, respectively relative to the expression in the non-specific siRNA group with IL-1β stimulation (Fig. 4A). Western blot results
verified that AQP1 siRNA-1 and -2 significantly decreased AQP1 expression at the protein level in chondrocytes with or without IL-1β stimulation when compared to the level in cells transfected with non-specific siRNA (Fig. 4B and C). These results indicated that the AQP1-specific siRNAs downregulated AQP1 at both the mRNA and protein levels. The level of ADAMTS-4 mRNA was also significantly decreased to 64.2 and 65.8% using AQP1 siRNA-1 and -2, respectively under IL-1β stimulation (Fig. 4F). However, the mRNA levels of MMP-3, MMP-13, ADAMTS-5, COL2A1, and ACAN were not significantly changed by the AQP1-specific siRNA transfection (Fig. 4D and E, and G-I). These results indicated that AQP1 downregulation decreased ADAMTS-4 expression in OA chondrocytes, but did not affect the expression of other related genes.

AQP1 and ADAMTS-4 were co-localized in chondrocytes. To investigate the relationship between AQP1 and ADAMTS-4, we assessed AQP1 and ADAMTS-4 expression with or without IL-1β stimulation in human articular chondrocytes using immunofluorescence. Representative single-color images showing DAPI, AQP1, and ADAMTS-4 staining, as well as merged images are shown (Fig. 5A). The results showed that in the absence of IL-1β stimulation, AQP1 was expressed, while ADAMTS-4 was not. Following IL-1β stimulation, the expression of both AQP1 and ADAMTS-4 was increased and the two molecules co-localized. However, AQP1 and ADAMTS-4 expression was decreased with AQP1-specific siRNA transfection. The results showed that AQP1-specific siRNA transfection reduced the percentage of AQP1 and ADAMTS-4 co-localization and ADAMTS-4 expression in OA chondrocytes (Fig. 5B and C).

Discussion

Geyer et al (21) showed that the increase in AQP1 expression in damaged tissues was restricted to chondrocytes in the superficial areas, while non-lesional regions of human OA of the knee displayed lack of AQP1 expression. Hagiwara et al (23) suggested that AQP1 is expressed in the articular cartilage of the knee in human, and the expression is localized in chondrocytes in both intact and early degenerative cartilage.
regions. In this study, we demonstrated that AQP1 was highly expressed in the superficial to middle zones of OA articular cartilages, and in the superficial zone of hip explant cartilages treated with IL-1β. The regions where AQP1 is expressed may be related to progression of OA. We also observed that OA chondrocytes had significantly higher levels of AQP1 mRNA compared to those in normal chondrocytes from hip cartilage.

Recent reports have also described various AQP1 functions other than its role in water-dependent homeostasis (28-30). Meng et al (30) demonstrated that AQP1 enhances the migration of bone marrow mesenchymal stem cells by regulating the focal adhesion kinase and β-catenin. Another study found enhanced MMP-2 and -9 expression upon AQP1 downregulation in LTEP-A2 and LLC lung cancer cell lines (29). In the present study, we demonstrated that the AQP1 downregulation decreased ADAMTS-4 expression in OA chondrocytes, but did not affect the expression of other catabolic genes. Further, we observed that AQP1 and ADAMTS-4 co-localized and the expression of ADAMTS-4 was decreased upon AQP1 downregulation in OA chondrocytes. Based on these results, AQP1 may directly affect ADAMTS-4 expression in OA chondrocytes.

ACAN is the principal cartilage extracellular matrix proteoglycan that gives cartilage its characteristic compressibility, while ADAMTS is a family of proteases (31). A previous study showed that downregulation of ADAMTS-5 expression protects mice from arthritis-induced ACAN degradation (32). In vitro, downregulation of ADAMTS-4 and ADAMTS-5 was associated with ACAN cleavage prior to collagen degradation by MMP-13 (33,34). ADAMTS-4 is predominantly expressed in OA cartilage, while ADAMTS-5 is constitutively expressed in both OA cartilage and normal hip cartilage. Further, the active form of ADAMTS-4 is overexpressed in OA chondrocytes, which directly correlates with the degradation of cartilage tissue (34). MMP and ADAMTS proteases cleave ACAN at different sites within the protein core (35). These findings supported our
results that AQP1 knockdown suppressed IL-1β-induced ADAMTS-4, but not ADAMTS-5, MMP-3, and MMP-13 expression.

Recently, Graziano et al (36) demonstrated a relationship between AQP1 and cartilage differentiation. However, we showed that AQP1 silencing did not affect MMP-13 expression in OA chondrocytes. Substantial phenotypic differences between differentiated chondrocytes used by Graziano et al (36) and OA chondrocytes in our study may explain the discrepancy. Cai et al (37) showed that AQP4 over-expression exacerbated the severity of adjuvant-induced arthritis in rat articular cartilages. This report supported our findings that AQP1 may control ADAMTS-4 expression in inflammatory chondrocytes. Nevertheless, further studies are needed to clarify the mechanism of IL-1β-induced ADAMTS-4 regulation by AQP1.

Our study had several limitations. First, synovial fluid is produced in the synovium, and AQP is known to function in water metabolism in tissues. However, AQP1 functions in the synovial tissue were not assessed in the present study and should be addressed in a future study. Second, a previous report showed that AQP1 expression positively correlated with caspase-3 expression and activity, suggesting that AQP1 promoted caspase-3 activation and thereby contributed to chondrocyte apoptosis and the development of OA (28). Thus, AQP1 roles in chondrocyte apoptosis should also be evaluated in future studies.

In conclusion, we demonstrated that AQP1 was highly expressed in the superficial to middle zones of OA articular cartilages, and the level of AQP1 mRNA was significantly higher in OA than in normal chondrocytes from hip cartilages. Further, AQP1 downregulation decreased ADAMTS-4 expression in OA chondrocytes, but did not change the expression of other catabolic and anabolic genes evaluated. We also observed the co-localization of AQP1 and ADAMTS-4 in OA chondrocytes. Our results indicated that AQP1 may play a role in maintaining the homeostasis of cartilage tissues; thus, catabolic factors may be suppressed by regulating AQP1 expression during OA progression.
