Central Limit Theorems for Radial Random Walks
on $p \times q$ Matrices for $p \to \infty$

Abstract

Let $\nu \in M^1([0, \infty[)$ be a fixed probability measure. For each dimension $p \in \mathbb{N}$, let $(X^p_k)_{n \geq 1}$ be i.i.d. $\mathbb{R}^p$-valued radial random variables with radial distribution $\nu$. We derive two central limit theorems for $\|X^p_1 + \ldots + X^p_n\|_2$ for $n, p \to \infty$ with normal limits. The first CLT for $n >> p$ follows from known estimates of convergence in the CLT on $\mathbb{R}^p$, while the second CLT for $n << p$ will be a consequence of asymptotic properties of Bessel convolutions.

Both limit theorems are considered also for $U(p)$-invariant random walks on the space of $p \times q$ matrices instead of $\mathbb{R}^p$ for $p \to \infty$ and fixed dimension $q$.

Keywords: Radial random walks, central limit theorems, random matrices, large dimensions, matrix cones, Bessel convolution, Bessel functions of matrix argument.

Classification: 60F05, 60B10, 60B12, 33C70, 43A62

1 Two central limit theorems

This paper has its origin in the following problem: Let $\nu \in M^1([0, \infty[)$ be a fixed probability measure. Then for each dimension $p \in \mathbb{N}$ there is a unique radial probability measure $\nu_p \in M^1(\mathbb{R}^p)$ with $\nu$ as its radial part, i.e., $\nu$ is the image of $\nu_p$ under the norm mapping $\varphi_p(x) := \|x\|_2$. For each $p \in \mathbb{N}$ consider i.i.d. $\mathbb{R}^p$-valued random variables $X^p_k$, $k \in \mathbb{N}$, with law $\nu_p$, as well as the associated radial random walks

$$(S^p_n := \sum_{k=1}^n X^p_k)_{n \geq 0}$$
on $\mathbb{R}^p$. The aim is to find limit theorems for the $[0, \infty]$-valued random variables $\|S_n\|_2$ for $n, p \to \infty$. In [V1] and [RV] we proved that for all sequences $p_n \to \infty$,

$$\|S_{n}^p\|_2^2/n \to \sigma^2 := \int_0^\infty x^2 \, d\nu(x)$$

under the condition $\sigma^2 < \infty$. Moreover, in [RV] an associated strong law and a large deviation principle were derived under the condition that $p_n$ grows fast enough. In this paper we present two associated central limit theorems (CLTs) under disjoint growth conditions for $p_n$.

The first CLT holds for $p_n \ll n$ and is an obvious consequence of Berry-Esseen estimates on $\mathbb{R}^p$ with explicit constants depending on the dimensions $p$, which are due to Bentkus and Götze [B], [BG2] (for a survey about this topic we also recommend [BGPR]):

1.1 Theorem. Assume that $\nu \in M^1([0, \infty[)$ with $\nu \neq \delta_0$ admits a finite third moment $m_3(\nu) := \int_0^\infty x^3 \, d\nu(x) < \infty$, and that $\lim_{n \to \infty} n/p_n^3 = \infty$. Then

$$\sqrt{p_n} \frac{\|S_n^p\|_2^2 - n\sigma^2}{n\sigma^2}$$

tends in distribution for $n \to \infty$ to the standard normal distribution $N(0,1)$.

Proof. The radial measure $\nu_p$ on $\mathbb{R}^p$ has a covariance matrix $\Sigma^2$ which is invariant under all conjugations w.r.t orthogonal transformations. Therefore, $\Sigma^2 = c_p I_p$ with the identity $I_p$ and some constant $c_p$. As $\sigma^2 = E(\|X^p\|^2_2) = p c_p$, we actually have $\Sigma^2 = (\sigma^2/p) I_p$. Theorem 2 of Bentkus [B] implies after normalization that the distribution function $F_{n,p}$ of $\sqrt{p_n} \|S_n^p\|^2_2$ and the distribution function $F_p$ of the $\chi^2_p$-distribution with $p$ degrees of freedom satisfy

$$\|F_{n,p} - F_p\|_\infty \leq C \cdot \frac{p^{3/2}}{\sqrt{n}}$$

(1.1)

for $n, p \in \mathbb{N}$ with a universal $C = C(\nu)$. Therefore, for $p = p_n$ as in the theorem, we have uniform convergence of distribution functions. Moreover, the classical CLT shows that for $\chi^2_p$-distributed random variables $X_p$ (with $E(X_p) = p$ and $\text{Var}(X_p) = 2p$), the random variables $X_p \frac{p}{\sqrt{2p}}$ tend to the standard normal distribution $N(0, 1)$ for $p \to \infty$. A combination of both results readily implies the theorem.

1.2 Remark. The main result of [BG2] suggests that for sufficiently large dimensions $p$ and $\nu \in M^1([0, \infty[)$ with finite fourth moment $m_4(\nu) := \int_0^\infty x^4 \, d\nu(x) < \infty$,

$$\|F_{n,p} - F_p\|_\infty \leq C \cdot \frac{p^2}{n} \quad (n, p \in \mathbb{N})$$

(1.2)
holds (the dependence of the constants is not clearly noted in [BG2] and difficult to verify). If (1.2) is true, then Theorem 1.1 holds under the weaker condition \( \lim_{n \to \infty} n/p_n^2 = \infty \). We also remark that the results of [BG1] indicate that the method of the proof of Theorem 1.1 above cannot go much beyond this condition.

In this paper, we derive the following complementary CLT for \( p_n \gg n \):

**1.3 Theorem.** Assume that \( \nu \in M^1([0, \infty[) \) admits a finite fourth moment \( m_4(\nu) := \int_0^{\infty} x^4 \, d\nu(x) < \infty \), and that \( \lim_{n \to \infty} n^2/p_n = 0 \). Then

\[
\frac{\|S_{p_n}^n\|_2^2 - n\sigma^2}{\sqrt{n}}
\]

tends in distribution for \( n \to \infty \) to the normal distribution \( N(0, m_4(\nu) - \sigma^4) \) on \( \mathbb{R} \).

**1.4 Remark.**

1. Assume that \( \nu \in M^1([0, \infty[) \) admits a finite fourth moment. A simple calculation then yields the moments up to order 4 where in particular

\[
E\left(\left(\|S_{p_n}^n\|_2^2 - n\sigma^2\right)^2\right) = n(m_4(\nu) - \sigma^4) + 2\frac{n(n-1)}{p_n}\sigma^4. \quad (1.3)
\]

These moments up to order 4 lead to the conjecture that the assertion of Theorem 1.1 holds precisely for \( n/p_n \to \infty \), and the assertion of Theorem 1.3 precisely for \( n/p_n \to 0 \). In fact, this was recently proved for measures having all moments by the moment convergence method by Grundmann [G]. He also obtains results for the case \( p_n = nc \).

2. A comparison of Theorems 1.1 and 1.3 has the following possible implication to statistics: Assume that \( \nu \in M^1([0, \infty[) \) is known and that the random variable \( \|S_{p_n}^n\|_2 \) can be observed with a known time parameter \( n \), but an unknown dimension \( p \) which has to be estimated. Then \( p \) can be recovered in a reasonable way for \( n \gg p^3 \) while this is not the case for \( n \ll \sqrt{p} \).

In this paper we shall also derive two generalizations of the preceding CLTs:

The first extension concerns a matrix-valued version: For fixed dimensions \( p, q \in \mathbb{N} \) let \( M_{p,q} = M_{p,q}(\mathbb{F}) \) be the space of \( p \times q \)-matrices over \( \mathbb{F} = \mathbb{R}, \mathbb{C} \) or the quaternions \( \mathbb{H} \) with real dimension \( d = 1, 2 \) or 4 respectively. This is a Euclidean vector space of real dimension \( dpq \) with scalar product \( \langle x, y \rangle = \Re \text{tr}(x^* y) \) where \( x^* := \overline{x^t}, \Re t := \frac{1}{2}(t + \overline{t}) \) is the real part of \( t \in \mathbb{F} \), and \( \text{tr} \) is the trace in \( M_q := M_{q,q} \). A measure on \( M_{p,q} \) is called radial if it is invariant under the action of the unitary group.
Up = Up(F) by left multiplication, Up × M_{p,q} → M_{p,q}, (u, x) ↦→ ux. This action is orthogonal w.r.t. the scalar product above, and, by uniqueness of the polar decomposition, two matrices x, y ∈ M_{p,q} belong to the same Up-orbit if and only if x∗x = y∗y. Thus the space U_{p,q}^U of Up-orbits in M_{p,q} is naturally parameterized by the cone Π_q = Π_q(F) of positive semidefinite q × q-matrices over F. We identify M_{p,q}^U with Π_q via U_qx ∼ (x∗x)^{1/2}, i.e., the canonical projection M_{p,q} → M_{p,q} will be realized as the mapping

ϕ_p : M_{p,q} → Π_q, x ↦→ (x∗x)^{1/2}.

The square root is used here in order to ensure for q = 1 and F = R that the setting above with Π_1 = [0, ∞] and ϕ_p(x) = ||x|| appears. By taking images of measures, ϕ_p induces a Banach space isomorphism between the space M_{p,q}^U of all bounded radial Borel measures on M_{p,q} and the space M_b(Π_q) of bounded Borel measures on the cone Π_q.

As in the case q = 1, we now consider for each p ∈ N i.i.d. M_{p,q}-valued random variables X_p^k, k ∈ N, with law ν_p and the associated radial random walks (S_p^n := ∑_{k=1}^n X_p^k)_{n≥0}.

1.5 Definition. We say that ν ∈ M^1(Π_q) admits a k-th moment (k ∈ N) if

m_k(ν) := \int_{Π_q} ||s||^k dν(s) < ∞

where ||s|| = (tr s^2)^{1/2} is the Hilbert-Schmidt norm. If the second moment exists, the second moment of ν is defined as the matrix-valued integral

σ^2 := σ^2(ν) := \int_{Π_q} s^2 dν(s) ∈ Π_q.

With these notions, the following generalizations of Theorems 1.1 and 1.3 hold:

1.6 Theorem. Assume that m_4(ν) < ∞. Moreover, let lim_{n→∞} n/p_n^4 = ∞. Then

\sqrt[p_n]{\frac{m_4(ν)}{n}} (ϕ_{p_n}(S_{p_n}^n)^2 - nσ^2)

tends in distribution to some normal distribution N(0, T^2) on the vector space H_q of hermitian q × q-matrices over F (with a covariance matrix T^2 = T^2(σ^2) described in the proof below for F = R).

Proof. We regard M_{p,q} = M_{p,q}(F) as F^p ⊗ F^q. The radial measure ν_p on M_{p,q} has a covariance matrix Σ_p^2 which is invariant under all
uniformly in all convex sets $L$.

Moreover, Theorem 1 of Bentkus [B] implies after normalization that there is an universal constant $C > 0$ with

$$|P(\frac{\sqrt{n}}{p} S_n^p \in K) - N(0, \Sigma^2(K))| \leq C \cdot \frac{p^2}{\sqrt{n}}$$

for all convex sets $K \subset M_{p,q}$ and all $n, p$. Therefore, for $p = p_n$ as in the theorem,

$$|P(\frac{p_n}{\sqrt{n}} S_n^{p_n} \in K) - N(0, \Sigma^2(K))| \to 0 \quad \text{for} \quad n \to \infty$$

uniformly in all convex sets $K \subset M_{p,q}$. Using the projections $\varphi_p : M_{p,q} \to \Pi_q$, we obtain

$$|P(\frac{p_n}{\sqrt{n}} \cdot \varphi_{p_n}(S_n^{p_n})^2 \in L) - W_{p_n}(L)| \to 0 \quad \text{for} \quad n \to \infty$$

uniformly in all convex sets $L \subset \Pi_q$ where the measures $W_{p_n} := \varphi_{p_n}(N(0, \Sigma^2))$ are certain Wishart distributions on $\Pi_q$ with $p_n$ degrees of freedom. By definition, the $W_{p_n}$ appear as the distribution of a $p_n$-fold sum of iid $W_1$-distributed random variables on the vector space $H_q$ with expectation $\sigma^2$ and some covariance matrix $T^2 = T^2(\sigma^2)$ described below. A combination of Eq. (1.4) and the classical CLT on $H_q$ then readily implies the theorem.

We finally compute $T^2$ for $F = \mathbb{R}$. Let $X = (X_1, \ldots, X_q)$ be a $\mathbb{R}^q$-valued, standard normal distributed random variable, and $\sigma \in \Pi_q$ the positive semidefinite root of $\sigma^2$. Then $Y := X\sigma$ is $\mathbb{R}^q$-valued with distribution $N(0, \sigma^2)$, and the $H_q$-valued random variable $Y^* Y = X^* \sigma^2 X$ has the distribution $W_1$. We notice that $E(X_i^2) = 3$, $E(X_i^2 X_j^2) = 1$ for $i \neq j$, and that $E(X_i X_j X_k X_l) = 0$ whenever at least one index appears only once in $\{i, j, k, l\}$. This implies

$$(T^2)_{(i,j), (k,l)} = \text{Kov}(Y_i Y_j, Y_k Y_l) = E(Y_i Y_j Y_k Y_l) - E(Y_i Y_j)E(Y_k Y_l)$$

$$= \sum_{a,b,c,d=1}^{q} \sigma_{a,i} \sigma_{b,j} \sigma_{c,k} \sigma_{d,l} E(X_a X_b X_c X_d) - \left(\sum_{a=1}^{q} \sigma_{a,i} \sigma_{a,j}\right) \left(\sum_{a=1}^{q} \sigma_{a,k} \sigma_{a,l}\right)$$

$$= \sum_{a,b=1}^{q} \left(\sigma_{a,i} \sigma_{a,k} \sigma_{b,j} \sigma_{b,l} + \sigma_{a,i} \sigma_{a,l} \sigma_{b,j} \sigma_{b,k}\right)$$

$$= (\sigma^2)_{i,k} (\sigma^2)_{j,l} + (\sigma^2)_{i,l} (\sigma^2)_{j,k}.$$  \hspace{1cm} (1.5)

The computation for $F = \mathbb{C}, \mathbb{H}$ is similar.

Notice that the proof is analog to that of Theorem [1.1]. The slightly stronger condition is required as here certain convex sets in $M_{p,q}$ instead of balls are used, where only weaker convergence results form [B].
are available. As for $q = 1$, we expect that Theorem 1.6 remains true under slightly weaker conditions than $n/p_n \to \infty$.

**1.7 Theorem.** Assume that $m_4(\nu) < \infty$ and $\lim_{n \to \infty} n^2/p_n = 0$. Then

$$\frac{1}{\sqrt{n}}(\varphi_{p_n}(S_n))^2 - n\sigma^2$$

tends in distribution to the normal distribution $N(0, \Sigma^2)$ on $H_q$ where $\Sigma^2$ is the covariance matrix of $\varphi_{p_n}(X^{p_n})$ (which is independent of $p_n$).

Notice that for $q = 1$, Theorem 1.7 completely agrees with 1.3. Theorem 1.7 will appear in Section 3 below as a special case of the even more general CLT 3.8.

We next turn to this generalization: Consider again the Banach space isomorphism $\varphi_p : M_b^{\nu}(M_{p,q}) \to M_b(\Pi_q)$. The usual group convolution on $M_{p,q}$ induces a Banach-$*$-algebra-structure on $M_b(\Pi_q)$ such that this becomes a probability-preserving Banach-$*$-algebra isomorphism. The space $\Pi_q$ together with this new convolution becomes a so-called commutative orbit hypergroup; see [J], [BH], and [R]. Moreover, for $p \geq 2q$, Eq. (3.5) and Corollary 3.2 of [R] show that the convolution of point measures on $\Pi_q$ induced from $M_{p,q}$ is given by

$$\langle \delta_r * \mu \delta_s(f) \rangle := \frac{1}{\kappa_{\mu}} \int_{D_q} f(\sqrt{r^2 + s^2 + se r + rv^*s}) \Delta(I - vv^*)^{\mu - \rho} \, dv$$

(1.6)

with $\mu := pd/2$, $\rho := d(q - \frac{1}{2}) + 1$,

$$D_q := \{ v \in M_q : v^*v < I \}$$

(where $v^*v < I$ means that $I - v^*v$ is positive definite), and with the normalization constant

$$\kappa_{\mu} := \int_{D_q} \Delta(I - v^*v)^{\mu - \rho} \, dv.$$  (1.7)

The convolution on $M_b(\Pi_q)$ is just given by bilinear, weakly continuous extension.

It was observed in [R] that Eq. (1.6) defines a commutative hypergroup $(\Pi_q, *_{\mu})$ for all indices $\mu \in \mathbb{R}$ with $\mu > \rho - 1$, where $0 \in \Pi_q$ is the identity and the involution is the identity mapping. These hypergroups are closely related with a product formula for Bessel functions $J_\mu$ on the cone $\Pi_q$ and are therefore called Bessel hypergroups. For details we refer to [FK], [H], and in particular [R]. For general indices $\mu$, these Bessel hypergroups $(\Pi_q, *_{\mu})$ have no group interpretation as in the cases $\mu = pd/2$ with integral $p$, but nevertheless the notion of random walks on these hypergroups is still meaningful. For $q = 1$, such structures and associated random walks were investigated by Kingman [K] and many others; see [BH].
1.8 Definition. Fix $\mu > p - 1$ and a probability measure $\nu \in M^1(\Pi_q)$. A Bessel random walk $(S_n^\mu)_{n \geq 0}$ on $\Pi_q$ of index $\mu$ and with law $\nu$ is a time-homogeneous Markov chain on $\Pi_q$ with $S_0^\mu = 0$ and transition probability

$$P(S_{n+1}^\mu \in A | S_n^\mu = x) = (\delta_x * \mu \nu)(A)$$

for $x \in \Pi_q$ and Borel sets $A \subset \Pi_q$.

This notion has its origin in the following well-known fact for the orbit cases $\mu = pd/2$, $p \in \mathbb{N}$: If for a given $\nu \in M^1(\pi_q)$ we consider the associated radial random walk $(S_n^p)_{n \geq 0}$ on $M_{p,q}$ as above, then $(\varphi_p(S_n^p))_{n \geq 0}$ is a random walk on $\Pi_q$ of index $\mu = pd/2$ with law $\nu$.

We shall derive Theorem 1.7 in Section 3 in this more general setting for $\mu \in \mathbb{R}$, $\mu \geq 2q$, as the proof is precisely the same as in the group case. The proof will rely on facts on these Bessel convolutions which we recapitulate in the next section.

We finally mention that it seems reasonable that at least for $q = 1$, Theorem 1.1 may be also generalized to Bessel random walks with arbitrary indices $\mu \in \mathbb{R}$ with $\mu \to \infty$. A possible approach might work via explicit Berry-Esseen-type estimates for Hankel transforms similar as in [PV] with a careful investigation of the dependence of constants there on the dimension parameter.

2 Bessel convolutions on matrix cones

In this section we collect some known facts mainly from [R] and [V2].

Let $F$ be one of the real division algebras $\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$ with real dimension $d = 1, 2$ or $4$ respectively. Denote the usual conjugation in $F$ by $t \mapsto \overline{t}$, the real part of $t \in F$ by $\text{Re} t = \frac{1}{2}(t + \overline{t})$, and by $|t| = (t\overline{t})^{1/2}$ its norm.

For $p, q \in \mathbb{N}$ we denote by $M_{p,q}$ the vector space of all $p \times q$-matrices over $F$ and put $M_q := M_q(F) := M_{q,q}(F)$ for abbreviation. Let further $H_q = \{x \in M_q : x = x^*\}$ the space of Hermitian $q \times q$-matrices. All these spaces are real Euclidean vector spaces with scalar product $\langle x, y \rangle := \text{Re} tr(x^*y)$ and norm $||x|| = \langle x, x \rangle^{1/2}$. Here $x^* := x^T$ and $tr$ denotes the trace. Let further

$$\Pi_q := \{x^2 : x \in H_q\} = \{x^*x : x \in H_q\}$$

be the cone of all positive semidefinite matrices in $H_q$. Bessel functions $J_\mu$ on these matrix cones with a parameter $\mu > 0$ (and suppressed parameters $F$ and $q$) were studied from different points of view by numerous people; we here only mention [H], [FK], [R], and [RV] which are relevant here. As we do not need details, we do not recapitulate the complicated definition here and refer to these references. We only
mention that for \( q = 1 \), and \( F = \mathbb{R} \), we have \( \Pi_q = [0, \infty[ \), and the Bessel function \( J_\mu \) satisfies

\[
J_\mu\left(\frac{x^2}{4}\right) = j_{\mu - 1}(x)
\]

where \( j_\kappa(z) = {}_0F_1(\kappa + 1; -z^2/4) \) is the usual modified Bessel function in one variable.

Hypergroups are convolution structures which generalize locally compact groups insofar as the convolution product of two point measures is in general not a point measure again, but just a probability measure on the underlying space. More precisely, a hypergroup \((X, *)\) is a locally compact Hausdorff space \(X\) together with a convolution \(*\) on the space \(M_b(X)\) of regular bounded Borel measures on \(X\), such that \((M_b(X), *)\) becomes a Banach algebra, and \(*\) is weakly continuous, probability preserving and preserves compact supports of measures. Moreover, one requires an identity \(e \in X\) with \(\delta_e \ast \delta_x = \delta_x \ast \delta_e = \delta_x\) for \(x \in X\), as well as a continuous involution \(x \mapsto \bar{x}\) on \(X\) such that for all \(x, y \in X\), \(e \in \text{supp}(\delta_x \ast \delta_y)\) is equivalent to \(x = \bar{y}\), and \(\delta_x \ast \delta_{\bar{y}} = (\delta_y \ast \delta_x)^{-}\). Here for \(\mu \in M_b(X)\), the measure \(\mu^{-}\) is given by \(\mu^{-}(A) = \mu(A^{-})\) for Borel sets \(A \subset X\). A hypergroup \((X, *)\) is called commutative if and only if so is the convolution \(*\). Thus for a commutative hypergroup \((X, *)\), \(M_b(X)\) is a commutative Banach-*-algebra with identity \(\delta_e\). Due to weak continuity, the convolution of measures on a hypergroup is uniquely determined by convolution products of point measures.

On a commutative hypergroup \((X, *)\) there exists a (up to a multiplicative factor) unique Haar measure \(\omega\), i.e. \(\omega\) is a positive Radon measure on \(X\) satisfying

\[
\int_X \delta_x \ast \delta_y(f)d\omega(y) = \int_X f(y)d\omega(y) \quad \text{for all} \; x \in X, f \in C_c(X).
\]

The decisive object for harmonic analysis on a commutative hypergroup is its dual space

\[
\hat{X} := \{ \varphi \in C_b(X) : \varphi \neq 0, \varphi(\bar{x}) = \overline{\varphi(x)}, \delta_x \ast \delta_y(\varphi) = \varphi(x)\varphi(y) \quad \text{for all} \; x, y \in X \}.
\]

Its elements are called characters. As for LCA groups, the dual of a commutative hypergroup is a locally compact Hausdorff space with the topology of locally uniform convergence and can be identified with the symmetric spectrum of the convolution algebra \(L^1(X, \omega)\). For more details on hypergroups we refer to [J] and [BH].

The following theorem contains some of the main results of [R].

**2.1 Theorem.** Let \( \mu \in R \) with \( \mu > \rho - 1 \). Then
(a) The assignment
\[
(\delta_r \ast_{\mu} \delta_s)(f) := \frac{1}{\kappa_{\mu}} \int_{D_q} f(\sqrt{r^2 + s^2 + s\langle vr, s \rangle}) \Delta(I-vr^*)^{\mu - \rho} \, dv
\]
for \(f \in C(\Pi_q)\) with \(\kappa_{\mu}\) as in (1.7), defines a commutative hypergroup structure on \(\Pi_q\) with neutral element \(0 \in \Pi_q\) and the identity mapping as involution. The support of \(\delta_r \ast_{\mu} \delta_s\) satisfies
\[
\text{supp}(\delta_r \ast_{\mu} \delta_s) \subseteq \{ t \in \Pi_q : \| t \| \leq \| r \| + \| s \| \}.
\]

(b) A Haar measure of \((\Pi_q, \ast_{\mu})\) is given by
\[
\omega_{\mu}(f) = \frac{\pi_{q\mu}}{\Gamma_{q\mu}(\mu)} \int_{\Omega_q} f(\sqrt{r}) \Delta(r)^{\gamma} \, dr \quad \text{with} \quad \gamma = \mu - \frac{d}{2} \left( q - 1 - 1 \right).
\]

(c) The dual space of \(\Pi_{q, \mu}\) is given by \(\hat{\Pi}_{q, \mu} = \{ \varphi_s : s \in \Pi_q \}\) with
\[
\varphi_s(r) := J_{\mu} \left( \frac{1}{4} rs^2 r \right) = \varphi_r(s).
\]
The hypergroup \(\Pi_{q, \mu}\) is self-dual via the homeomorphism \(s \mapsto \varphi_s\). Under this identification of \(\Pi_{q, \mu}\) with \(\hat{\Pi}_{q, \mu}\), the Plancherel measure on \(\Pi_{q, \mu}\) is \((2\pi)^{-2\mu q} \omega_{\mu}\).

The most important informal observation at this point is that the convolution (2.1) converges for \(\mu \to \infty\) to the semigroup convolution
\[
(\delta_r \bullet \delta_s)(f) := f(\sqrt{r^2 + s^2}), \quad r, s \in \Pi_q
\]
associated with the semigroup operation \(r \bullet s := \sqrt{r^2 + s^2}\) on \(\Pi_q\). We next shall make this convergence more precise, as this is the main ingredient for the proof of Theorem 1.7.

3 The central limit theorem for \(\mu_n \gg n\)

We here derive a generalization of Theorem 1.7 for general parameters \(\mu\). We begin with some unusual notion which is needed below:

3.1 Definition. A function \(f : \Pi_q \to \mathbb{C}\) is called root-Lipschitz continuous with constant \(L\), if for all \(x, y \in \Pi_q\),
\[
|f(\sqrt{x}) - f(\sqrt{y})| \leq L \|x - y\|.
\]

3.2 Lemma. There is a constant \(C = C(q)\) such that for all \(r, s \in \Pi_q\), all \(\mu \geq 2\rho\), and all root-Lipschitz continuous functions \(f\) on \(\Pi_q\) with constant \(L\),
\[
|\delta_r \ast_{\mu} \delta_s(f) - \delta_r \bullet \delta_s(f)| \leq CL \|r\| \cdot \|s\| / \sqrt{\mu}.
\]
Proof. We first recapitulate from Lemma 3.1 of [RV] that for \( \mu > \rho \) and \( v \in \sqrt{\mu} \cdot D_q \subset M_q \),

\[
0 \leq e^{-(v,v)} - \Delta(I - \frac{1}{\mu}vv^*)^\mu \leq \frac{1}{\mu} \text{tr}((vv^*)^2) \cdot e^{-(v,v)}.
\]  

(3.1)

As all norms on \( \Pi_q \) are equivalent, we conclude from the first inequality that for \( r, s > 0 \) and suitable constants \( C_i \),

\[
|\delta_r^\mu \delta_s(f) - \delta_r \cdot \delta_s(f)| 
\leq \frac{1}{\kappa_\mu} \int_{D_q} \left| f(\sqrt{r^2 + s^2 + svr + rv^*s}) - f(\sqrt{r^2 + s^2}) \right| \cdot \Delta(I - vv^*)^{\mu - \rho} \text{d}v 
\leq \frac{L}{\kappa_\mu} \int_{D_q} \|svr + rv^*s\| \cdot \Delta(I - vv^*)^{\mu - \rho} \text{d}v 
\leq \frac{C_1 L \|r\| \cdot \|s\|}{\kappa_\mu} \int_{D_q} \|v\| \cdot \Delta(I - vv^*)^{\mu - \rho} \text{d}v 
\leq \frac{C_1 L \|r\| \cdot \|s\|}{\kappa_\mu (\mu - \rho)^{(dq^2 + 1)/2}} \int_{M_q} \|v\| \cdot e^{-(v,v)} \text{d}v 
\leq C_2 \frac{L \|r\| \cdot \|s\|}{\kappa_\mu (\mu - \rho)^{(dq^2 + 1)/2}}
\]

(3.2)

Moreover, the second inequality in (3.1) yields that for sufficiently large \( \mu \),

\[
\kappa_\mu = \int_{D_q} \Delta(I - v^*v)^{\mu - \rho} \text{d}v 
\geq \frac{1}{(\mu - \rho)^{dq^2/2}} \int_{\sqrt{\mu - \rho} \cdot D_q} \Delta(I - \frac{1}{\mu - \rho}vv^*)^{\mu - \rho} \text{d}v 
\geq \frac{1}{(\mu - \rho)^{dq^2/2}} \int_{\sqrt{\mu - \rho} \cdot D_q} \left(1 - \frac{\text{tr}((vv^*)^2)}{\mu - \rho}\right) e^{-(v,v)} \text{d}v 
\geq C_3 (\mu - \rho)^{-dq^2/2}
\]

and thus \( \kappa_\mu \geq C_4 (\mu - \rho)^{-dq^2/2} \) for all \( \mu \geq 2\rho \) and some constant \( C_3 \). The lemma is now a consequence of Eq. (3.2).

\[ \square \]

3.3 Lemma. There is a constant \( C = C(q) \) such that for all root-Lipschitz continuous functions \( f \) on \( \Pi_q \) with constant \( L \), all \( \nu_1, \nu_2 \in M^1(\Pi_q) \) with \( m_1(\nu_1) < \infty \), and all \( \mu \geq 2\rho \),

\[
|\nu_1^\mu \nu_2(f) - \nu_1 \cdot \nu_2(f)| \leq CL \cdot m_1(\nu_1) \cdot m_1(\nu_2) / \sqrt{\mu}.
\]

10
Proof. By Lemma 3.2

\[ |(\nu_1 \ast_{\mu} \nu_2) \ast_{\nu} \nu_3(f) - \nu_1 \ast_{\nu} \nu_2 \ast_{\nu} \nu_3(f)| \]
\[ \leq \int_{\Pi_q} \int_{\Pi_q} |\delta_r \ast_{\mu} \delta_s(f) - \delta_r \ast_{\nu} \delta_s(f)| \, d\nu_1(r) \, d\nu_2(s) \]
\[ \leq \frac{CL}{\sqrt{\mu}} \int_{\Pi_q} \int_{\Pi_q} \|r\| \cdot \|s\| \, d\nu_1(r) \, d\nu_2(s) = CL \frac{m_1(\nu_1)m_1(\nu_2)}{\sqrt{\mu}}. \]

\[ \square \]

3.4 Lemma. There is a constant \( C = C(q) \) such that for all root-
Lipschitz continuous functions \( f \) on \( \Pi_q \) with constant \( L \), all \( \nu_1, \nu_2, \nu_3 \in M^1(\Pi_q) \) with \( m_1(\nu_1) < \infty \), and all \( \mu \geq 2\rho \),

\[ |(\nu_1 \ast_{\mu} \nu_2) \ast_{\nu} \nu_3(f) - (\nu_1 \ast_{\nu} \nu_2) \ast_{\nu} \nu_3(f)| \leq CL \cdot m_1(\nu_1) \cdot m_1(\nu_2) / \sqrt{\mu}. \]

Proof. For \( y \in \Pi_q \), consider the function \( f_y(x) := f(x \cdot y) \) on \( \Pi_q \).
By the definition of \( \ast \) and our definition of root-Lipschitz continuity,
these \( f_y \) are also root-Lipschitz continuous with the same constant \( L \).
Therefore, by Lemma 3.3

\[ \left| (\nu_1 \ast_{\mu} \nu_2) \ast_{\nu} \nu_3(f) - (\nu_1 \ast_{\nu} \nu_2) \ast_{\nu} \nu_3(f) \right| \]
\[ \leq \int_{\Pi_q} \left| \int_{\Pi_q} f_y(x) \, d(\nu_1 \ast_{\mu} \nu_2)(x) - \int_{\Pi_q} f_y(x) \, d(\nu_1 \ast_{\nu} \nu_2)(x) \right| \, d\nu_3(y) \]
\[ \leq CL \cdot m_1(\nu_1) \cdot m_1(\nu_2) / \sqrt{\mu}. \]

\[ \square \]

For \( \nu \in M^1(\Pi_q) \) and \( n \in N \), we denote the \( n \)-fold convolution powers of \( \nu \) w.r.t. the convolutions \( \ast_{\mu} \) and \( \ast \) by \( \nu^{(n, \ast_{\mu})} \) and \( \nu^{(n, \ast)} \) respectively.

3.5 Lemma. For all \( \nu \in M^1(\Pi_q) \) with \( m_2(\nu) < \infty \), and all \( n \in N \), \( \mu > \rho - 1 \),

\[ m_1(\nu^{(n, \ast_{\mu})}) \leq \sqrt{n \cdot m_2(\nu)}. \]

Proof. By the definition of the convolution \( \ast_{\mu} \), the function \( m_2 \) satisfies

\[ \delta_r \ast_{\mu} \delta_s(m_2) = m_2(r) + m_2(s) + \frac{1}{\kappa_{\mu}} \int_{D_q} tr(rvsv^*r) \cdot \Delta(I - vv^*)^{\mu - \rho} \, dv \]
for \( r, s \in \Pi_q \) where the symmetry of the integrand and the substitution \( v \mapsto -v \) immediately yield that the integral is equal to 0. Therefore,

\[ \delta_r \ast_{\mu} \delta_s(m_2) = m_2(r) + m_2(s). \]
Therefore, by the Cauchy-Schwarz inequality,

\[ m_2(\nu_1 * \nu_2) = m_2(\nu_1) + m_2(\nu_2). \]

In particular we obtain by induction that for \( \nu \in M^1(\Pi_q) \) with \( m_2(\nu) < \infty \) and \( n \in \mathbb{N} \),

\[ m_2(\nu^{(n, \ast)}) = n \cdot m_2(\nu). \]

Therefore, by the Cauchy-Schwarz inequality,

\[ m_1(\nu^{(n, \ast)}) = \int_{\Pi_q} \|x\| d\nu^{(n, \ast)}(x) \leq \left( \int_{\Pi_q} \|x\|^2 d\nu^{(n, \ast)}(x) \right)^{1/2} = \sqrt{n \cdot m_2(\nu)}. \]

\( \square \)

3.6 Remark. The preceding lemma has the following weaker variant under a weaker moment condition: For all \( \nu_1, \nu_2 \in M^1(\Pi_q) \) and all \( \mu > \rho - 1 \),

\[ m_1(\nu_1 * \nu_2) \leq m_1(\nu_1) + m_1(\nu_2). \]

For the proof, observe that the convolution \( *_{\mu} \) has the property that for \( r, s \in \Pi_q \),

\[ \text{supp}(\delta_r *_{\mu} \delta_s) \subset \{ t \in \Pi_q : \|t\| \leq \|r\| + \|s\| \}; \]

see for instance Theorem 3.10 of [R]. Therefore,

\[
m_1(\nu_1 *_{\mu} \nu_2) = \int_{\Pi_q} \int_{\Pi_q} \left( \int_{\Pi_q} \|r\| d(\delta_r *_{\mu} \delta_y)(r) \right) d\nu_1(x) d\nu_2(y) \\
\leq \int_{\Pi_q} \int_{\Pi_q} (\|x\| + \|y\|) d\nu_1(x) d\nu_2(y) \\
= m_1(\nu_1) + m_1(\nu_2)
\]

as claimed.

3.7 Proposition. Let \( \nu \in M^1(\Pi_q) \) with \( m_2(\nu) < \infty \). Then there is a constant \( C = C(q, \nu) \) such that for all root-Lipschitz continuous functions \( f \) on \( \Pi_q \) with constant \( L \), and all \( n \geq 2 \), \( \mu \geq 2 \rho \),

\[ |\nu^{(n, \ast)}(f) - \nu^{(n, \bullet)}(f)| \leq CL \frac{\rho^{3/2}}{\sqrt{\mu}}. \]

Proof. We first observe that

\[
|\nu^{(n, \ast)}(f) - \nu^{(n, \bullet)}(f)| \\
\leq |\nu^{(n, \ast)}(f) - \nu^{(n-1, \ast)}(f)| + |(\nu^{(n-2, \ast)} \ast \nu)(f) - \nu^{(n-2, \ast)} \ast \nu \ast \nu(f)| \\
+ \ldots + |(\nu \ast \nu) \ast \nu^{(n-2, \ast)}(f) - \nu^{(n, \ast)}(f)|.
\]
Moreover, by Lemmas 3.4 and 3.5 we have for \( k = 2, \ldots, n \) that
\[
\left| \nu^{(k, \mu)} \bullet \nu^{(n-k, \bullet)}(f) - \nu^{(k-1, \mu)} \bullet \nu^{(n-k, \bullet)}(f) \right| \\
\leq m_1(\nu^{(k-1, \mu)}) \cdot m_1(\nu) \cdot \frac{C_1 L}{\sqrt{\mu}} \\
\leq C_1 L \frac{\sqrt{k-1}}{\sqrt{\mu}} m_1(\nu) \cdot \sqrt{m_2(\nu)}
\]
with a suitable constant \( C_1 > 0 \). Combining this with the preceding inequality and \( \sum_{k=1}^{n} \sqrt{k} = O(n^{3/2}) \), the proposition follows.

We now fix a probability measure \( \nu \in M^1(\Pi_q) \) and consider for \( \mu > \rho \), the associated random walk \((S^n_\mu)_{n \in \mathbb{N}}\) on \( \Pi_q \) with law \( \nu \) according to Definition 1.8.

3.8 Theorem. Let \( \nu \in M^1(\Pi_q) \) with a finite fourth moment \( \int_{\Pi_q} \|x\|^4 d\nu(x) < \infty \). Assume that \( n^2/\mu_n \to 0 \) for \( n \to \infty \). Then
\[
\frac{(S^n_\mu)^2 - n\sigma^2}{\sqrt{n}}
\]
tends in distribution for \( n \to \infty \) to the normal distribution \( N(0, \Sigma^2) \) on the vector space \( H_q \) of Hermitian \( q \times q \) matrices, where \( \Sigma^2 \) is the covariance matrix belonging to the image measure \( Q(\nu) \in M^1(\Pi_q) \subset M^1(H_q) \) under the square mapping \( Q(x) := x^2 \) on \( \Pi_p \).

Proof. Let \( f \in C_0(H_q) \) be a Lipschitz-continuous function in the usual sense on \( H_q \) with the Lipschitz constant \( L \). Then, for \( n \in \mathbb{N} \), the functions
\[
f_n(x) := f\left(\frac{x^2 - n\sigma^2}{\sqrt{n}}\right)
\]
on \( \Pi_q \) are root-Lipschitz with constants \( n^{-1/2}L \). Therefore, by Proposition 3.7 and the assumptions of the theorem,
\[
\left| \int_{\Pi_q} f_n d\nu^{(n, \mu)} - \int_{\Pi_q} f_n d\nu^{(n, \bullet)} \right| \leq CL \frac{n}{\sqrt{\mu_n}} \to 0 \quad (3.3)
\]
for \( n \to \infty \) with
\[
\int_{\Pi_q} f_n d\nu^{(n, \mu)} = \int_{\Pi_q} f_n dP_{S^n_\mu} = \int_{\Pi_q} f dP_{((S^n_\mu)^2 - n\sigma^2)/\sqrt{\mu_n}} \quad (3.4)
\]
where \( P_X \) denotes the law of a random variable \( X \). Moreover, as the square mapping \( Q(x) := x^2 \) is an isomorphism from the semigroup
(\Pi_q, \bullet) onto the semigroup (\Pi_q, +), and denoting the classical convolution of measures on \Pi_q \subset H_q associated with the operation + by *, we see that

\[
\int_{\Pi_q} f_n \, d\nu^{(n, \bullet)}(x) = \int_{\Pi_q} \frac{x^2 - n\sigma^2}{\sqrt{n}} \, d\nu^{(n, \bullet)}(x) = \int_{\Pi_q} \frac{x - n\sigma^2}{\sqrt{n}} \, dQ^{(n, \bullet)}(x) = \int_{\Pi_q} \frac{x - n\sigma^2}{\sqrt{n}} \, dQ^{(n, \bullet)}(x)
\]

(3.5)

where the latter tends by the classical central limit theorem on the euclidean space H_q to \( \int_{H_q} f \, dN(0, \Sigma^2) \). Taking (3.3) and (3.4) into account, we obtain that

\[
\int_{H_q} f \, dP_{((S_n^\mu)^2 - n\sigma^2) / \sqrt{n}} \to \int_{H_q} f \, dN(0, \Sigma^2)
\]

(3.6)

for \( n \to \infty \). As the space of Lipschitz continuous functions in \( C_0(H_q) \) is \( \| \cdot \|_\infty \)-dense in \( C_0(H_q) \), a simple \( \varepsilon \)-argument together with the triangle inequality ensures that Eq. (3.6) holds for all \( f \in C_0(H_q) \). This completes the proof.

We briefly consider the case of point measures \( \nu = \delta_x \). In this case we have \( \Sigma^2 = 0 \) and we do not need to apply the classical CLT above. In particular, the first part of the preceding proof leads to the following weak law:

3.9 Corollary. Let \( (a_n)_{n \geq 1} \subset [0, \infty) \) an increasing sequence with \( a_n = o \left( \frac{n^{3/2}}{\mu_n^2} \right) \) for \( n \to \infty \). If \( \nu = \delta_x \) for some \( x \in \Pi_q \), then

\[
\frac{(S_n^\mu)^2 - nx^2}{a_n} \to 0 \quad \text{in probability.}
\]

In particular, for \( a_n := n \) and \( n/\mu_n \to 0 \), we obtain \( S_n^\mu / \sqrt{n} \to x \).

We note that this particular result was derived under much weaker conditions on the \( \mu_n \) in [RV] by different methods.

We finally note that a similar CLT is derived in [V3] for radial random walks on the hyperbolic spaces when time and dimension tend to infinity similar as above.
