Lignocellulose is the most abundant biomass on earth. Agricultural, forest, and agroindustrial activities generate tons of lignocellulosic wastes annually, which present readily procurable, economically affordable, and renewable feedstock for various lignocelluloses based applications. Lignocellulases are the focus of present decade researchers globally, in an attempt to develop technologies based on natural biomass for reducing dependence on expensive and exhaustible substrates. Lignocellulolytic enzymes, that is, cellulases, hemicellulases, and lignolytic enzymes, play very important role in the processing of lignocelluloses which is prerequisite for their utilization in various processes. These enzymes are obtained from microorganisms distributed in both prokaryotic and eukaryotic domains including bacteria, fungi, and actinomycetes. Actinomycetes are an attractive microbial group for production of lignocellulolytic enzymes. Various studies have evaluated the lignocellulose degrading ability of actinomycetes, which can be potentially implemented in the production of different value added products. This paper is an overview of the diversity of cellulolytic, hemicellulolytic, and lignolytic actinomycetes along with brief discussion of their hydrolytic enzyme systems involved in biomass modification.

1. Introduction

Actinomycetes, a separate taxonomic group within domain bacteria, are members of the order Actinomycetales [1]. They are Gram positive bacteria, primarily aerobic and spore formers, with high G+C content [2]. As their name reflects (in Greek, “aktis” means ray and “mykes” means fungus), they share some morphological features with fungi [3]. They show filamentous growth, producing aerial or substrate mycelium. Actinomycetes are responsible for earthy smell of the soil [1]. They are ubiquitous in nature, found both in terrestrial and aquatic habitats [1, 4], including mangroves and sea sediments [5]. They belong to both mesophilic and thermophilic groups [6], which broaden the range of habitats inhabited by them. Actinomycetes are known to produce an extensive range of bioactive compounds including various enzymes having multiple biotechnological applications.

Lignocellulolytic enzymes, one of the potent enzymes produced by actinomycetes, can be exploited widely in various lignocelluloses based industries [7]. Lignocellulases are hydrolytic enzymes capable of degrading tough lignocellulose in the plant biomass and include cellulases, hemicellulases, and lignolytic enzymes [8]. Lignocellulose is the most abundant renewable biomass on earth [9]. It refers to the main constituents of the plant matter, that is, cellulose, hemicellulose, and lignin [10]. Hydrolysis of lignocellulosic biomass is accomplished by lignocellulolytic enzymes, which are used in diverse applications [11]. Cellulases are used in production of bioethanol and biomethane, in ligand binding studies [12], textile industry, pulp and paper making, detergents industry, animal feed and food, and so forth [13]. Hemicellulases are employed in biobleaching, deinking of paper waste, clarification of fruit juices, upgrading of feed, fodder and fibres, and saccharification of hemicelluloses to xylose sugars [14]. Applications of lignin-degrading enzymes involve pretreatment of recalcitrant lignocellulosic biomass for biofuel production, use in paper industry, textile industry, food industry, wastewater treatment, bioremediation, organic synthesis, and cosmetic and pharmaceutical industries [15].

Lignocellulolytic enzymes can be obtained from diverse types of microorganisms including bacteria and fungi [16]. Among bacteria actinomycetes are an attractive group, being...
tapped for production of lignocellulases [7, 17–20]. In this review, the diversity and applications of lignocellulolytic actinomycetes have been discussed along with description of their lignocellulases enzyme systems involved in biomass degradation.

2. Lignocellulose: Structure and Uses

Lignocellulose is comprised of three main components, that is, cellulose, hemicellulose, and lignin [21] (Figure 1). Cellulose is the high molecular weight linear polymer of D-glucopyranose units linked together by β-(1→4)-glycosidic bonds, with cellobiose dimer being the repeating unit. The cellulose chains are hydrogen bonded to each other, making a bundle of microfibrils, which further aggregate together to make cellulose fibrils [22]. The structure shows variations from amorphous to crystalline regions. The cellulose fibrils are packed in the cell wall in a matrix of hemicelluloses and lignin [23]. Hemicelluloses are linear or branched heteropolysaccharides composed of D-xylose, L-arabinose, D-galactose, D-glucose, or D-mannose sugars with or without different uronic acids and may include xylans, mannans, glucans, glucuronoxylans, arabinoxylans, glucomannans, galactomannans, galactoglucomannans, β-glucans, and xyloglucans [10, 24]. The branching and composition vary among different plant sources. Xylan, the polymer of xylose, is the most abundant hemicellulosic component [10]. Lignin is a very complex polyphenolic heteropolymer primarily made up of three phenyl propionic alcohol monomers, that is, p-coumaryl alcohol, coniferyl alcohol, and sinapyl alcohol [25].

Figure 1: Chemical structure of lignocellulose.
3. Lignocellulolytic Enzyme Systems in Actinomycetes

3.1. Cellulases. Cellulolytic enzymes are a group of glycosyl hydrolases classified into different families depending on their sequence homologies. The mechanisms of action and substrate specificities vary among different cellulases, but they are generally divided into exoglucanases (EC 3.2.1.74), endoglucanases (EC 3.2.1.4), cellobiohydrolases (EC 3.2.1.91), and β-glucosidases (EC 3.2.1.21) [36, 37]. Exoglucanases act on reducing or nonreducing ends of cellulose chains releasing glucose units, whereas endoglucanases hydrolyse β-1,4-glycosidic bonds randomly inside the cellulose chains releasing dextrans of variable lengths [38]. Cellobiohydrolases cleave glycosidic bonds at nonreducing ends and release cellobiose units [39]. These enzymes are particularly important in hydrolysing crystalline cellulose because of their processivity [36]. β-glucosidases enzymes take part in hydrolysis of cellobiose units to monomeric glucose [38]. Complete hydrolysis of cellulose involves synergistic effect of all these enzymes, showing synergy between endoglucanases and exoglucanases (endo-exo synergy), exoglucanases acting on the reducing and nonreducing ends (exo-exo synergy), between cellobiohydrolases and β-glucosidases, and between catalytic and carbohydrate binding domains [39]. Figure 2 shows schematic presentation of enzymatic hydrolysis of cellulose polymer.

Microbial cellulase systems are either complexed or noncomplexed [39]. Complexed systems, known as cellulosomes, are characteristics of anaerobic bacteria, consisting of multienzyme complex protuberances from cell surface stabilized by dockerin and adhesion proteins. In aerobic bacteria, including most of the actinomycetes, cellulases are noncomplexed or free and are secreted extracellularly using specific secretion pathways.

Among cellulase producing actinomycetes, *Cellulomonas fimi*, *Microbispora bispora*, and *Thermobifida fusca* have been studied extensively [6, 39]. *Thermobifida fusca* is a thermophile, spore forming actinomycete [6]. The genome of *T. fusca* consists of 3.6 billion bp in a single circular chromosome, with 3117 coding sequences, and has 67.5% G+C content which stabilizes DNA in extreme temperature conditions [40]. The genome encodes for 36 glycoside hydrolases distributed in 22 GH (glycoside hydrolases) families [40]. Cellulase system of *T. fusca* is comprised of six extracellular cellulases (4 endocellulases and 2 exocellulases) and one intracellular β-glucosidase [6, 40–42]. Each enzyme has a separate catalytic and carbohydrate binding domain, both linked together with a linker peptide [36, 41]. Carbohydrate binding domains in all six cellulases belong to the same family, that is, 2CBD [41]. The catalytic domains, however, are different in all enzymes belonging to different families, with Cel5A and Cel5B from GH family 5, Cel6A and Cel6B from GH family 6, Cel9A and Cel9B from GH family 9, and Cel48A from family 48 [43]. Cel5A, Cel5B, Cel6A, and Cel9B are endocellulases and do not show processivity [36, 40, 41]. Cel6B and Cel48A are processive exocellulases which act at nonreducing and reducing ends, respectively. Cel9A is a novel processive cellulase with both exo- and endocellulase actions, starting exo-hydrolysis from the nonreducing end [36]. The position of CBD varies in different cellulases, which is N-terminus in Cel5A, Cel6B, and Cel48A and C-terminus in Cel6A, Cel9A, and Cel9B [41]. Sequence studies of catalytic domains have revealed less than 31% similarity between...
enzymes from taxonomically similar as well as dissimilar microbes, which indicates development of cellulase system as a result of horizontal gene transfer compared to the gene duplication [44]. The three-dimensional structure of Ck6A shows α·β barrel with a deep active site cleft formed by one shorter and one turned loop, consisting of four conserved Asp residues [42, 45]. Active site of GH48 is also in a cleft [42]. Structural characteristics of exocellulases allow them to bind processively, whereas open active sites of endocellulases enable them to bind cellulose internally at random sites [42]. Structural elucidation of Cel9A has shown that it gives activity between exo- and endocellulases because its weak binding domain 3c CBD is aligned with the active site in the catalytic domain, allowing processive hydrolysis by the enzyme [42]. T. fusca also produces cellulose and chitin binding proteins, E7 and E8, the CBM33 proteins which improve cellulose hydrolysis mediated through exoglucanases [36, 40, 42]. Cellulases from T. bifida have also been found showing synergism with endocellulases and Trichoderma reesei CBHI [6].

Cellulomonas fimi is a facultative anaerobe, but it does not consist of cellulosomes of cellulolytic anaerobes; rather it produces free cellulases [46]. Similarly, facultatively anaerobic Cellulomonas flavigena also secretes free cellulases [46]. Both carry out efficient hydrolysis of celluloses and hemicelluloses. The cellulase enzyme systems in Cellulomonas fimi also consist of six cellulases [39], that is, three endocellulases (CenA, CenB, and CenD), two exocellulases (CbhA and CbhB), and a processive endocellulase, CenC [41, 46]. All these enzymes have activities similar to that in T. bifida, with some families of CBDs (2CBD) and catalytic domains, but different sequences [41, 47]. These cellulases are primarily secreted by sec dependent pathway [46] and, therefore, do not require intracellular folding or cofactors for their activity. In C. fimi ATCC 484 and C. flavigena ATCC 482, another enzyme GH94 (cellulbiose phosphorylase) has also been discovered [46]. Microbispora bispora also shows synthesis of six different cellulases, showing exo-exo and endo-exo synergism [6]. Genomic studies of Streptomyces sp. SirexAA-E (ActE), isolated from pine-boring woodwasp Sirex noctilio, have also shown genes for GH48 (CBH activity), GH74 (endocellulase), and CDB33 [48]. Streptomyces coelicolor consisted of 221 carbohydrate active enzymes (CAZy) or 154 glycosyl hydrolases (GHs), encoded within 8.6 billion bp long genome [48].

The expression of cellulolytic genes in T. bifida is induced by cellulbiose, whereas easily utilizable sugar glucose shows catabolite repression as in most of the other cellulolytic microbes [49]. The regulation of cellulolytic genes is mediated by the CelR repressor, which binds to a 9–14 bp palindrome

**Figure 2:** Scheme of cellulose hydrolysis.
Enzyme Research

T. bifida using either one or both of the common bacterial systems (EC3.2.1.22)[36,51]. Mannanases hydrolyze \( \beta \)-mannosidases, mainly utilizes TAT systems for protein export[40]. secretionsystem and genes expression is also regulated by cAMP levels.

The extracellular cellulases are secreted by actinomycetes using either one or both of the common bacterial systems for secretion of extracellular proteins, that is, sec general secretion system and sec independent twin-arginine translocation (TAT) systems. The general Secretion route catalyses transmembrane translocation of proteins in their unfolded conformation, whereas Twin-arginine (TAT) system translocates secretory proteins in their native folded state. In T. bifida both of these systems were discovered, whereas S. coelicolor mainly utilizes TAT systems for protein export[40].

3.2. Hemicellulases. Hemicellulases are generally synthesised along with cellulases [36, 39]. Xylan and mannans are most abundant components of hemicelluloses. Complete hydrolysis of xylan involves an enzyme system consisting of endo-1,4-\( \beta \)-xylanases (EC 3.2.1.8), \( \beta \)-D-xyllosidases (EC 3.2.1.37), \( \alpha \)-L-arabinofuranosidas (EC 3.2.1.55), \( \alpha \)-glucuronidas (EC 3.2.1.139), acetyl xylan esteras (EC 3.1.1.72), and feryllic/coumaric acid esteras (EC 3.1.1.73). Mannan is hydrolysed primarily by synergistic action of mannanases (EC 3.2.1.78), \( \beta \)-mannosidas (EC 3.2.1.25), and \( \alpha \)-galactosidas (EC 3.2.1.22) [36, 51]. Mannanases hydrolyze \( \beta \)-1,4-glycosidic bonds internally, \( \beta \)-mannosidase cleave \( \beta \)-1,4 linked mannosose from nonreducing ends, and \( \alpha \)-galactosidase removes terminal D-galactosyl residues linked by \( \alpha \)-1,6 linkages [52]. Degradation of mannan and xylan also enhances cellulose hydrolysis as they are known to inhibit cellulase activities [36].

Most of the hemicellulases belong to glycosyl hydrolases families; however, some enzymes involved in hemicellulose hydrolysis belong to glycosyltransferases (EC 2.4.1.x) [39]. Xylanases, hydrolysing internal \( \beta \)-1,4-glycosidic bonds, are classified into GH families 5, 7, 8, 10, 11, and 43. \( \beta \)-D-xylidosidase hydrolyse xylose monomers from nonreducing ends of xylan oligosaccharides and belong to GH families 3, 39, 43, 52, and 54 [53]. Studies have indicated production of several xylanases by T. bifida and other actinomycetes. T. bifida has been found to be producing \( \beta \)-1,4-endoxylanases (xyII0A, xyII0B, and xill1A), xylidosidases, \( \alpha \)-L-arabinofuranosidas, xyl glucanases, \( \beta \)-1,3-glucanases (GH10), and \( \alpha \)-N-arabinofuranosidas (xil43) [36, 40]. Cellulomonas fimi synthesizes extracellular endo- as well as exo-xylanases: xylan binding domain CBM4, \( \beta \)-mannanase, mannosidase, and xel74 (xyl glucan specific \( \beta \)-1,4-glucanase) [36, 46]. Cellulomonas flavigena ATCC 482 are known to synthesize an unusual mixture of 19 endoxylanases, along with GH10, GH11, and GH30 xylanases; GH43 (\( \beta \)-xyllosidase), GH51 \( \alpha \)-arabinofuranosidase, and \( \alpha \)-glucuronidase; GH26 and GH13 manannans; and GH16 and GH81 \( \beta \)-glucanase [46]. Streptomyces flavogriseus has shown production of \( \beta \)-1,4 glucan glucohydrolase [54]. Xylanase genes GH5 (\( \beta \)-mannanosidase), GH10 (beta xylanase), GH11 (beta xylanase), CE4 (acetylxylan esterase) and GH6 (CBH), and GH9 (CBH) have also been found in Streptomyces sp. SirexAA-E (ActE)[48].

3.3. Lignolytic Enzymes. Lignin degradation is mediated by a complex of enzymes containing three principal enzymes laccases (EC 1.10.3.2), manganese peroxidases (MnP, EC 1.11.1.13), and lignin peroxidases (LiP, EC 1.11.1.14) [55, 56]. Laccases are the oxidoreductases which degrade polyphenol, the principal recalcitrant component in the lignocellulose [15, 57]. They are extracellular inducible enzymes which employ simple oxygen as an oxidizing agent as well as cofactor. They are multicopper oxidases having four copper atoms in their active sites, taking part in oxygen reduction [58]. Low substrate specificity of laccases enables them to degrade wide variety of compounds. Manganese and lignin peroxidases are together known as heme peroxidases containing protoporphyrin IX as a prosthetic group. Lignin peroxidases can specifically degrade high redox potential compounds and are known to oxidize phenolic as well as nonphenolic aromatic rings, which make up around 90% of the lignin polymer. They require \( \text{H}_2\text{O}_2 \) for their activity. Veratryl alcohol is an attractive substrate for LiP, which oxidises other substrates by acting as the redox mediator for indirect oxidation. Manganese peroxidases are low redox potential heme peroxidases requiring \( \text{H}_2\text{O}_2 \) for their activity. They can be manganese dependent or versatile peroxidases [56, 58].

Laccases or Laccase-like multicopper oxidases containing (LMCO) four copper atoms are classified in types 1, 2, and 3 [57, 59]. The four copper atoms are distributed in three domains in most of the bacterial and fungal laccases [60]. Structural studies in several actinomycetes, however, have revealed presence of two Cu-binding domains, rather than three [61, 62]. The two-domain structure has been named as small laccase or small LMCO [59, 61]. LMCOs in Streptomyces griseus, Streptomyces cyaneus, Streptomyces coelicolor, Streptomyces ipomoea, Streptomyces sviceus, Streptomyces sp., and Thermobifida fusca are active as dimers or trimmers [61, 63, 64].

4. Genetic Engineering

The genes from several lignocellulolytic actinomycetes have been successfully cloned to show heterologous expression in different microbes. GH1 and GH3 enzymes of C. fimi ATCC 484 expressed in E. coli have shown efficient hydrolysis of cellulases and xylanases [65]. CelStrep gene from cellulytic Streptomyces sp. G12 cloned and expressed in E. coli was found to belong to GH12 family and catalysed hydrolysis of carboxymethylcellulose following a Michaelis-Menten kinetics with a \( K_m \) of 9.13 mg/mL and a \( V_{max} \) of 3469 \( \mu \text{M} \text{min}^{-1} \) [66]. Streptomyces reticuli consists of Cell gene encoding for avicelase enzyme which alone can hydrolyse crystalline cellulose effectively [67]. When this gene was cloned and expressed in E. coli, Bacillus subtilis, and Streptomyces spp., enzyme was produced but in lower amounts probably due to the absence of genes encoding for essential regulatory factors [68]. From xylanolytic Actinomadura sp strain FC7 two genes, xyII and xyIII, have been cloned, expressed, and
well characterized in *Streptomyces lividans* [69]. Xylanase gene xylBS27 belonging to GHI from *Streptomyces* sp. S27 has been successfully cloned and expressed in *Pichia pastoris*, hydrolysing xylan to xylooligosaccharides [70]. Similarly, expression of laccase gene from *Streptomyces coelicolor* (SLAC) in *Streptomyces lividans* produced large amount of high purity laccase (350 mg L⁻¹) [71]. The gene for a thermostable laccase from *Streptomyces lavendulae* REN-7 was successfully cloned and expressed in *E. coli* [72]. Cloning of a lignin peroxidase from *Streptomyces viridosporus* T7A into *Streptomyces lividans* TK64 has resulted in better lignocellulose degradation by genetically engineered *S. lividans* compared to *S. lividans* TK64 [73]. Thus, genetic engineering techniques can be and are being used for constructing industrially valuable strains with potent applications based on actinomycetes lignocellulolytic enzymes.

### 5. Diversity of Lignocellulolytic Actinomycetes

#### 5.1. Cellulolytic Actinomycetes

Cellulolytic potential of actinomycetes has been explored since inspection of other microorganisms for cellulase production. Various research studies support high cellulose degradation potential of microbes from actinomycetales. Table I represents the diversity of actinomycetes producing cellulase enzymes.

#### 5.2. Hemicellulolytic Actinomycetes

Diverse types of actinomycetes belonging to wide range of habitats and active in different environmental conditions are known to produce hemicellulolytic enzymes. *Streptomyces* have been found to be the most abundant hemicellulases producer among actinomycetes. In a study by Boroujeni et al. [74], all of the isolated hemicellulolytic actinomycetes were found to belong to *Streptomyces* genus. Xylanase has been successfully purified from *Streptomyces* sp. E-86 and characterized for its xylanolytic activity [75]. Optimization studies were carried out for endoxylanase production by *Streptomyces* sp. F2621 isolated from Turkey [76]. β-xylanolide activity of *Streptomyces* has been used in saccharification of ball milled wheat straw [77]. A thermostable xylanase was obtained from *Streptomyces* sp. QG-11-3, which has shown biobleaching effects in eucalyptus kraft pulp [78]. Xylanase has also been produced from other strains of *Streptomyces* sp. such as *Streptomyces* sp. strain CI-3 [79], *Streptomyces* sp. CD3 [80], *Streptomyces* sp. 7b [81], *Streptomyces* sp PC22, *Streptomyces* sp 234P-161, SWU-10, *Streptomyces* sp. MDS [82], and *Streptomyces* sp. [83]. In *Streptomyces rochei* and *Streptomyces chromofuscus*, xylanase production has been achieved using treated Papyrus and cotton stalk pulp. The obtained xylanase when used for studying bleaching effects has shown enhanced brightness in the presence of EDTA [84]. Xylanases have also been obtained from *Streptomyces albus* and *Streptomyces hygroscopicus* and have shown successful production of biogas using oil cake and straw waste [85].

In a study by Ninawe et al. [86], three *Streptomyces* isolates, that is, *Streptomyces cyaneus*, *S. tendae*, and *S. caelestis*, were found to be xylanolytic and the enzyme from *Streptomyces cyaneus* was successfully purified followed with its characterization [87]. *Streptomyces thermoviolaceus* OPC-520 exhibited production of acetyl xylan esterases and α-L-arabinofuranosidases enzymes [88]. Extracellular xylanase production has also been observed in *Streptomyces aureofaciens* [89] and in *Streptomyces coelicolor* grown on different agricultural wastes such as sugarcane bagasse, pineapple, orange, and pomegranate peels [90]. Xylanases from *Streptomyces albus* and *Streptomyces chromofuscus* have indicated positive bleaching effects in rice straw pulp [91]. Bhosale et al. [92] have shown production of 326 IU/mL of xylanases from *Streptomyces rameus* using sugarcane bagasse along with peptone and dextrose [92]. Studies have indicated production of cellulase free xylanases from *Streptomyces roseiscleroticus* [93, 94] and *Saccharomonomospora viridis* [95]. Improvement in xylanase production has also been seen in *Thermomonospora fusca* [77, 97]. *Thermomonospora curvata*, *Thermomonospora alba*, *Micromonospora*, *Microbipora bispora*, *Nocardia*, *Saccharomonomospora viridis*, and *Thermoactinomyces* have shown production of β-xylanolides, acetylxyrases, and arabinofuranosidases [77]. Extracellular xylanases have been partially purified and characterized in *Microbipora siamensis* in a study by Boondaen et al. [98]. Xylanase production has also been observed in *Microtetraspora flexuosa* [99], *Streptomyces chattanoogensis* UAH 23 [100], *Streptomyces chattanoogensis* CECT 3336 [101], *Streptomyces viola coacrum* [102], *Thermoactinomyces thalophilus* [103], *Thermomonospora* sp. [104], *Streptomyces thermocyanaeoviolaceus* [105], and *Streptomyces lividans* [106]. The enzyme from *Streptomyces lividans* was purified and characterized by different researchers [107, 108]. *Microbipora* sp. has been found to be producing hemicellulolytic mannanase enzyme [109], whereas other studies have indicated production of β-xylanolides by *Streptomyces albocres modulus*, *S. nitrosporeus*, and *Micromonospora melanospora* [110].

#### 5.3. Lignolytic Actinomycetes

Lignolytic activity is exhibited by diverse range of actinomycetes, which play important role in biodegradation processes in the environment. Search is in progress for more actinomycetes with high lignolytic potential, using advanced techniques combined with conventional methods. A study by Fernandes et al. [111] have used specifically designed primers for detection of laccase-like genes within actinomycetes and has identified gene fragments undetectable by known primers, which corresponded to superfamilies I and K based on laccase and multicopper oxidase engineering database. Arias et al. [112] have shown production of laccase by *Streptomyces cyaneus* CECT 3335 using soya flour. Laccase was purified and characterized and was found to show increase in brightness of eucalyptus kraft pulp in biobleaching studies. The enzyme was able to oxidize veratryl alcohol suggesting potential of the strain in industrial applications. Veratryl alcohol oxidation and other lignolytic activities have also been demonstrated in *Streptomyces viridosporus* [113, 114].

*Streptomyces* sp. strain EC-22, strain EC1, *Streptomyces badius*, *Streptomyces cyaneus* MT813, *Thermomonospora fusca*, *Thermomonospora chromogena*, *Thermomonospora*
### Table 1: Cellulase producing actinomycetes.

| Actinomycete isolate | Cellolytic enzyme | Observed results | Reference |
|----------------------|------------------|------------------|-----------|
| *Streptomyces* sp.   | β-glucosidases   | Saccharification of rice straw | [77] |
|                      | Extracellular cellulases | Zone of hydrolysis in plate assay method | [109, 130] |
|                      | Endoglucanases    | Enzyme production | [131] |
|                      | Cellulases        | Aid in composting | [132] |
|                      | Carboxymethylcellulose (Cx) and Avicelase (Ci) enzyme | Production of enzymes | [133] |
| *Streptomyces* sp. strain AT7 | Endoglucanases/CMCase (carboxymethylcellulose) | CMCase production | [76, 134, 135] |
| *Streptomyces* sp. strains M7a and M7b, F2621, LIPIMC-A-194, LIPIMC-A-251, and LIPIMC-A-278 | Cellulases | Scale-up of enzyme production | [136] |
| *Streptomyces* sp. T3-1 | Cellulases | Enzyme production using fruit waste | [137] |
| *Streptomyces* albofuscosus, *Streptomyces* nitrosporus | β-glucosidase, endoglucanase, and avicelase | Optimization studies for production of cellulases | [100] |
| *Streptomyces* lividans | Cellulases | Enzyme characterization | [106] |
| *Streptomyces* flavogriseus | Cellulases | Enzyme production optimization | [138] |
| *Streptomyces* nitrosporus | Cellulases | Optimization of enzyme production | [138] |
| *Streptomyces* albopulmonis | Exoglucanase, β-glucosidase, and endoglucanase | Catabolite repression studies | [139] |
| *Streptomyces* reticus | Avicelase | Characterization of enzyme | [140] |
| *Streptomyces* cellulolyticus | Extracellular cellulases | Cellulose decomposition | [141] |
| *Streptomyces* dendrococci | Endoglucanase | Successful application in detergent and textile processing | [142] |
| *Streptomyces* malachitofuscus, *Streptomyces* gramineus, and *Streptomyces* strobiligerus | Extracellular cellulases | Zone of hydrolysis in plate assay method | [109] |
| *Streptomyces* ganadicus | Extracellular cellulase, CMCase/endoglucanase | Zone of hydrolysis in plate assay method | [109, 143] |
| *Streptomyces* actinomycus | Endoglucanase | Optimization of CMCase production | [144] |
| *Streptomyces* globosus, *Streptomyces* alanoscinicus, *Streptomyces* ruber | CMCase/endoglucanase | CMCase production | [135] |
| *Cellulomonas* fimi | Cellulase | Enzyme production from agroindustrial residues | [145] |
| *Streptomyces* viridochromogenes | Avicelase, CMCase, and total cellulase | Saccharification of rice straw and ethanol production | [146] |
| *Streptomyces* albofuscosus | Extracellular cellulases | Degradation of cellulolytic materials | [147] |
| *Streptomyces* griseorubens | Cellulases | Enzyme production optimization | [148] |
| *Streptomyces* matensis | Endoglucanase and exoglucanase | Enzyme production optimization | [149] |
| *Streptomyces* longipororuber | Carboxymethylcellulose | Production and purification of enzyme | [150] |
| *Cellulomonas* fimi | Cellulase | Activity observed, saccharification of rice straw and ethanol production, and optimization of enzyme production using wheat straw | [151] |
|                      | FPase (total cellulases) | | [152] |

mesophilia, Amincolata autotrophica, and Micromonaspora sp. have shown significant activities against lignin related compounds [115, 116]. Past et al. [117] have shown lignolytic activity in Streptomyces chromofuscus, Streptomyces diastaticus, and Streptomyces rochei. Several actinomycetes such as Streptomyces coelicolor, Streptomyces griseus, and Nocardia and several strains of Streptomyces sp. isolated from termite Amitermes hastatus have indicated production of laccases, lignin peroxidases, or manganese peroxidases enzymes by them [118]. Laccase and lignin peroxidase activities have also been observed in Streptomyces cinnamomeus [119]. Laccase enzyme studies were carried out including their structural elucidation in Streptomyces lavendulae, Streptomyces psammothicus, Streptomyces ipomoaeae, and Streptomyces sviceus [61]. In a study by Escudero et al. [120], Tsukamurella and Cellulosimicrobium actinomycetes showed ABTS (2,2′-azino-bis-3-ethylbenzothiazoline-6-sulphonic acid) oxidation rate of 108 U/L and 0.56 U/L, respectively [120]. Submerged fermentation in marine actinomycete Streptomyces lydicus, isolated from Egypt Red Sea, grown in medium supplemented with peanut shell, produced 1.625 U/mL laccase under optimized conditions [121]. Thermoaalkali stable laccase from Thermobifida fusca has shown oxidation of several dye intermediates including 2,6-dimethylenylaniline and p-aminophenol [64]. Streptomyces sviceus was also found to be showing lignolytic activity [63]. Streptomyces psammothicus has shown enhanced production of laccase under solid state fermentation conditions in the presence of pyrogallol inducer, which was taken to the level of scale-up studies using a packed bed bioreactor [122]. Study by Niladevi and Prema [123] has shown production of all three enzymes, that is, laccase, manganese peroxidase, and lignin peroxidase, by Streptomyces psammothicus. Actinomycete Rhodococcus ruber has shown oxidation and degradation of polyethylene as a result of laccase production by it [124]. A study by Aoyama et al. [125] demonstrated laccase production by Streptomyces atratus. In search of the genes involved in lignocellulose degradation during composting of agricultural wastes, two-domain laccase-like multicopper oxidase genes were identified in Streptomyces violaceusniger [62]. Rhodococcus jostii was found to produce lignin peroxidases capable of modifying lignin [126]. Several other studies have shown lignin degradation ability in many other actinomycetes including Streptomyces flavovirens [127], Streptomyces setoni [128], Actinomadura spp. [55], and Streptomyces thermoviolaceus [129].

6. Future Prospects

Owing to the abundance and renewability of lignocellulosic biomass, it is considered as most appropriate and economical feedstock for production of various industrially useful products. Lignocellulases enzymes are, therefore, critical in processes associated with bioconversion of lignocelluloses. Presently most of the commercially exploited lignocellulases rely on fungal or bacterial microorganisms. Actinomycetes are relatively less explored for their biomass hydrolysis potential. The studies can be elaborated in search of new actinomycetes producing lignocellulose degrading enzyme systems. Different feedstock shows variation in their chemical composition. The production of enzymes needs to be optimized for different biomass. The production of lignocellulases from all microbial sources is still quite expensive. Efforts can be made for reducing the cost of production of these enzymes using high potency actinomycete enzyme systems with broader range of tolerance and active at diverse environmental conditions. Genetic engineering techniques can be used to construct enzyme systems with desirable characteristics. Also the studies can be expanded gradually to scale up to the industrial levels for their subsequent adoption in commercial processes.

7. Conclusion

Actinomycetes are an important source of lignocellulose hydrolysing enzymes. They constitute considerable proportion of the soil or aquatic microflora responsible for biomass degradation in nature. The research studies on search of lignocellulose hydrolysing actinomycetes revealed the abundance and diversity of these microbes in different ecological niches. The genetic and protein studies on their hydrolytic enzymes lead to the elucidation of structural and mechanism details of enzymes and their relatedness with other known lignocellulose producers and their enzyme systems. Relatively scantly information is available on lignocellulosylotic actinomycetes. The research studies, therefore, need to be elaborated in view of utilization of lignocellulosylotic potential of actinomycetes applicable in different industrial sectors.

Conflict of Interests

The authors declare that there is no conflict of interests regarding publication of this review article.
