Abstract. Environmentally friendly methods for obtaining nanomaterials see a great interest. In addition to being inexpensive, the easy implementation process and the advantages of synthesis without toxic chemicals are the main reasons of interest. In this study, silver nanoparticles (AgNPs) were successfully synthesized using fig (*Ficus carica*) leaf extract. The formation and the presence of AgNPs were observed using ultraviolet-visible spectrophotometry (UV-Vis). Peaks with a maximum wavelength of 419 nm are identified in the measurements. Phytochemicals in the extract responsible for functional groups providing reduction and stability were evaluated using Fourier transform infrared spectroscopy (FT-IR) data. The Scanning electron microscopy-Energy Dispersive X-Ray Spectrum (SEM-EDX) analysis showed that the AgNPs were spherical and the elemental composition contained mostly silver. X-ray diffractometer (XRD) results revealed that the peaks 111°, 200°, 220° and 311° belong to the characteristic structure of silver and have a crystal dimension of 17.30 Nm using Debye-Scherrer equation. In thermogravimetric - differential thermal analysis (TGA-DTA) analysis, the degradation temperatures of AgNPs were evaluated. AgNPs showed antimicrobial activity on various microorganisms even at very high concentrations. As a solution to the antimicrobial search, it can be developed in medical industry.

Keywords: XRD, SEM, TGA-DTA, AgNPs, *Ficus carica*

Introduction

Nanomaterials are used in medical, electronic, food and cosmetic industries, textile industry, agricultural applications and many other areas (Alqahtani et al., 2017; El-Batal et al., 2018; Silva-Ichante et al., 2018; Rolim et al., 2019). Among nanomaterials, AgNPs have a large facial area, good thermal and electrical conductivity (Elemike et al., 2016). AgNP are obtained using different methods (*Fig. 1*) (Mittal et al., 2013). Since physical and chemical methods are being synthesized by using high amounts of energy and toxic chemicals, they are a disadvantage compared to biological methods. Biological source synthesis methods are cheaper and the process is simpler and easier. It also makes these methods more advantageous because they do not contain toxic chemicals during the synthesis phase (Pantidos and Horsfall, 2014; Tippayawat et al., 2016; Kanchi et al., 2018). Phytochemicals such as polyphenols, flavonoids, proteins, alcohols and sugars found in plants, rather than harmful chemicals, are responsible for both reduction and stability (Kumar et al., 2015). Phytochemicals are responsible for the synthesis of AgNPs by reducing the Ag+ form to AgO (Prakash et al., 2013). Obtaining nanoparticles from plant sources provides advantages such as easy processing and no culture (Pallela et al., 2018). Furthermore, AgNPs have been shown to exhibit antimicrobial activity in some studies (Veerasamy et al., 2011; Ghosh et al., 2012; Ashajyothi et al., 2016).
The aim of this study is to synthesize AgNPs with fig (Ficus carica) leaf extract in an inexpensive and simple way and to investigate the anti-microbial effects of these NPs characterized by different analysis data.

Materials and methods

Plant leaf

Fig (Ficus carica) leaf used in the study was obtained from Mardin, Sultan Village/Turkey in May-June 2018. 500 g samples stored in the Microbiology-Biochemistry Research Laboratory of Mardin Artuklu University.

Microorganisms

For testing antimicrobial activity; Escherichia coli ATCC 25922, Staphylococcus aureus ATCC 25923, Streptococcus pyogenes ATCC 19615 Pseudomonas aeruginosa ATCC 27853, standard bacterial strains with Candida albicans ATCC 10231 strains are available in the Microbiology-Biochemistry Research Laboratory of Mardin Artuklu University.
Preparation of fig (Ficus carica) leaf extract and silver nitrate (AgNO₃) solution

The green leaves of fig fruit were collected in the center of Mardin, Sultan Village/Turkey. After washing with tap water, washing was done several times with distilled water. Dried leaves were minimized prior to preparation of the extract. 100 g was taken and mixed with 500 ml distilled water and left to boil. After boiling, the room was cooled and filtered several times by using the rough filter paper first and then the Whatman No.1 filter paper. After being filtered for several times, it was kept at +4 °C for synthesis. 1 mM aqueous solution was prepared with silver nitrate (AgNO₃) of 99.8% purity was purchased from Alfa Aesar.

Synthesis and characterization

500 ml extract and 2000 ml AgNO₃ solution were mixed and kept constant in room conditions. The color change was observed for 50 min depending on the time. The presence of AgNPs was checked by examining absorbance values for the color change using Perkin Elmer one UV Visible Spectrophotometer. The characterization of silver nanoparticles was carried out as follows according to the methods described earlier (Baran, 2018). FTIR analysis was performed to evaluate phytochemicals responsible for reduction by using Perkin Elmer Spectrum One. The post-synthesized content in liquid form was centrifuged with OHAUS FC 5706 model device at 6,000 rpm for 25 min and the particles used for further characterization steps were precipitated. The particles were dried at 65 °C. RadB-DMAX II computer-controlled Energy Dispersive X-Ray diffractometer (EDX) was used to evaluate the elemental composition of the particles. Morphological images were examined with scanning electron microscope EVO 40 LEQ (SEM) data. The crystal structure of the particles was evaluated by RadB-DMAX II computer-controlled X-ray diffractometer (XRD) analysis. Crystalline particle size was determined by using the debye-Scherrer equation, using the Shimadzu TGA-50 device to control the decomposition temperature of the particles with TGA-DTA.

Determination of antimicrobial effects of silver nanoparticles

The antimicrobial effects of the particles on gram negative Escherichia coli ATCC 25922, P. aeruginosa ATCC 27853, gram positive Staphylococcus aureus ATCC 29213, S. pyogenes ATTC 19615 bacteria and Candida albicans yeast were determined by using micro dilution method to determine the minimum inhibition concentration (MIC). In practice, the muller Hilton medium was added to the microplate wells and incubated overnight at 37 °C by addition of an appropriate amount of the microorganism mixture and the AgNP solution adjusted to 0.5 in turbidity according to the Mc Farland standard. The lowest concentration in the absence of reproduction after incubation was determined as the MIC value (El-Batal et al., 2018; Vishwasrao et al., 2018). Commercial antibiotics were used as control for Gram (+) (vancomycin), Gram (-) (colistin) bacteria and fungus (fluconazole). In addition, the effect of AgNO₃ solution was investigated. The study was performed with 3 repetitions and the mean values were determined as MIC value.

Results and discussion

After mixing 1 mM AgNO₃ solution with leaf extract, the color rapidly changed from light to dark brown was observed after 30 min. Maximum absorbance data at 419 nm is given in Figure 2.
Functional groups involved in the reduction of AgNPs were investigated by FTIR analysis (Fig. 3).

In the XRD results, the peaks 111°, 200°, 220° and 311° are the peaks that correspond to 2θ, which represent the cubic crystal structure of silver (Fig. 4). The numerical values corresponding to these peaks were found to be 38.10, 44.24, 64.54 and 77.50. The crystal size of AgNPs were calculated 17.30 nm by using the Debye-Scherrer formula (Eq. 1) (Baran, 2019).

\[
D = \frac{K\lambda}{(\beta \cos \theta)} \quad (\text{Eq. 1})
\]

In Equation 1: D = particle size (nm), K = fixed (0.90), \(\lambda\) = wavelength X-ray (1.5406Å), \(\beta\) = half of the highest peak value is specified in radians (FWHM), \(\theta\) = fracture angle.

When the SEM analysis data were examined, it was found that AgNPs were in spherical appearance (Fig. 5).
Figure 4. Investigation of crystal structure and silver phases of AgNPs by XRD analysis

Figure 5. Evaluation of morphology of AgNPs in SEM results

The results of EDX showed a large percentage of the element content (Fig. 6). The TGA-DTA findings of the synthesized AgNPs were analyzed at a flow rate of 20 mL/min in the N₂ (g) atmosphere with a heating rate of 10 °C/min between 12 and 1000 °C (Fig. 7) (Eren and Baran, 2019).

In the study, AgNPs were found to be effective at lower concentrations than antibiotic and 5 mM silver nitrate solution. The MIC values of *S. aureus*, *S. pyogenes E. coli P. aeruginosa* and *C. albicans* respectively 0.225, 0.056, 0.112, 0.112 and 0.450 mg L⁻¹ results were obtained (*Table 1*). Compared with silver nitrates and antibiotics, AgNPs synthesized using plant extract can be used as an alternative to existing antibiotics as a result.
In the synthesis of AgNPs using the fig leaf extract, the dark brown color change vibrations on the plasma surface and the UV-Vis. The data on the maximum absorbance of 419 nm in spectrophotometer measurements gives us characteristic data showing the formation and presence of AgNPs (Link and Wang, 1999; Hemmati et al., 2019). In similar synthesis studies of plant origin there are values of absorbance supporting this data (Shahverdi et al., 2007; Kumar et al., 2017; Selvakumar et al., 2018). The peak at
3529 cm\(^{-1}\) is \(-\text{NH}\) stretching, the peak at 1599 cm\(^{-1}\) may belong to \(-\text{C} = \text{O}\) or I amide band, and the peak in cm\(^{-1}\) 3180 is considered to be phenol or alcohol-induced-OH. During the formation of nanoparticles, role of -OH, -NN and C = O groups shift in the reduction is shown. In the synthesis studies to obtained AgNPs, almost identical functional groups were said to be responsible for reduction (Baran, 2019). In the XRD results, the peaks 111°, 200°, 220° and 311° are the peaks that correspond to 2 0, which represent the cubic crystal structure of silver. Some studies have characterized these data with AgNPs (Narayanan and Sakthivel, 2010; Hemmati et al., 2019). The crystal size of AgNPs was calculated 17.30 nm by using the Debye-Scherrer formula. After the synthesis of nanoparticles, there are studies that calculate crystal size using this equation (Senapati et al., 2014; Palanisamy et al., 2017). The SEM results indicate that AgNPs have spherical morphology. In other studies, it has been reported that AgNPs have a spherical appearance (Pugazhendhi et al., 2018; Vishwasrao et al., 2018; Rolim et al., 2019).

**Table 1. MIC values of Synthesized silver nanoparticles (AgNP) (mg mL\(^{-1}\)) on Silver nitrate solution and vancomycin, fluconazole, colistin antibiotics, S. Aureus, S. pyogenes, S. albicans and E. Coli, P. aeruginosa microorganisms**

| Organism          | AgNPs | Silver nitrat | Antibiotic |
|-------------------|-------|---------------|------------|
| Gram positive     |       |               |            |
| S. aureus ATCC 29213 | 0.225 | 2.65          | 1          |
| S. pyogenes ATCC 19615 | 0.056 | 1.32          | 1          |
| Gram negative     |       |               |            |
| E. coli ATCC25922 | 0.112 | 0.66          | 2          |
| P. aeruginosa ATCC 27853 | 0.112 | 0.66          | 2          |
| Fungi             |       |               |            |
| C. albicans       | 0.450 | 0.66          | 2          |

In the EDX analysis, it was observed that the content of the element belonged largely to silver. In similar studies, the element composition was evaluated (Owaid et al., 2015; Khan et al., 2018; Acay et al., 2019). In TGA-DTA data, it is understood that the mass loss of the nanoparticles at 12-232 °C is due to moisture and the mass loss at 232-467 °C is due to the structure of the extract and that the material is now gradually degraded at 467-876 °C in Figure 5 (Baran et al., 2018; Baran, 2019). We have investigated the effective antimicrobial activity of AgNPs. This activity was effective even at lower concentrations than commercial antibiotic and 5 mM silver nitrate solution. Studies have shown that AgNPs have a negative effect on the reproduction of microorganisms and that they have put pressure on them (Pugazhendhi et al., 2018). These NPs produce ROS (Reactive Oxygen Species), suppressing the membrane structure, proteins, DNA and other vital functions of microorganisms and suppressing their function (Acay et al., 2019). Environmentally friendly synthesis methods for the production of nanomaterials are in the focus of interest due to their lack of toxic chemicals, economical and easier synthesis process. At the same time, the fields of use are becoming widespread every day.
Conclusions

The advantages of nanoparticles synthesized by biological methods are hygienic working environment, health and environmental protection, less waste and providing the most stable products. Green-synthesized Ag-NPs can be evaluated in a variety of applications including cardiovascular implants, dentistry, medicine, therapeutics, biosensors, agriculture and more, both now and in the future. In this context, it was revealed that these particles are in a spherical view with a maximum absorption of 419 nm and that the crystal particle size is 17.30 nm. The degradation temperatures of these AgNPs were found to be 876 °C, and this is an indication of the durability of the product. It was found that these particles showed strong anti-microbial activity. NPs increasingly used for medical applications are of great interest as an approach to killing or reducing the activity of a large number of microorganisms. As a result, the AgNPs obtained is an alternative that can be developed and used in biotechnological and medical applications.
