(Dated: February 5, 2008)

The thermodynamics of low dimensional spin-1/2 Heisenberg ferromagnets (HFM) in an external magnetic field is investigated within a second-order two-time Green function formalism in the wide temperature and field range. A crucial point of the proposed scheme is a proper account of the analytical properties for the approximate transverse commutator Green function obtained as a result of the decoupling procedure. A good quantitative description of the correlation functions, magnetization, susceptibility, and heat capacity of the HFM on a chain, square and triangular lattices is found for both infinite and finite-sized systems. The dependences of the thermodynamic functions of 2D HFM on the cluster size are studied. The obtained results agree well with the corresponding data found by Bethe ansatz, exact diagonalization, high temperature series expansions, and quantum Monte Carlo simulations.

I. INTRODUCTION

Quantum Heisenberg model with ferromagnetic exchange is used extensively to interpret the thermodynamic and magnetic properties of low dimensional (1D and 2D) physical systems. Examples of quasi-one-dimensional ferromagnets whose properties can be explained within the Heisenberg model are organic p-NPNN compounds [12,13] and cuprates [14]. The ferromagnetic insulators such as $K_2CuF_4$, $Cs_2CuF_4$, $La_2BaCuO_4$, $Rb_2CrCl_4$ and quantum Hall ferromagnets [15,16] provide examples of the Heisenberg system on a square lattice. A unique example of a spin-1/2 magnet on a triangular lattice is $^3$He bilayers adsorbed on graphite [17,18,19]. At high coverages the second layer proved to be a solid ferromagnet whose thermodynamics can be described by HFM with a high degree of accuracy [20,21]. Nowadays, considerable study is being given to $^3$He monolayers on $^4$He-preplated graphite substrates. In these systems under high enough pressure a solid $^3$He monolayer with ferromagnetic exchange is formed [22].

Experimental research of the aforementioned low dimensional magnets is carried out intensively, in particular, in the presence of an external magnetic field. To interpret the experimental data it is necessary to develop a quantitative description of the HFM thermodynamics at arbitrary magnetic fields and temperatures. The two-time Green function formalism is quite appropriate for this purpose. The method based on one or another decoupling scheme for higher Green functions results in a closed set of self-consistent equations for thermodynamic averages [23,24]. Random phase approximation (RPA) is the simplest variant of such scheme with decoupling at the first step [25,26]. Being applied to the low dimensional systems it gives satisfactory results at high fields whereas at low and intermediate fields RPA describes the thermodynamics only on a qualitative level.

A quantitative description of 1D and 2D spin systems can be obtained within a more complicated scheme originally proposed in Ref. [23] for 1D HFM in zero magnetic field. The scheme is based on the decoupling of higher Green functions at the second step with introducing the vertex parameters to be found. A proper choice of the vertex parameters makes it possible to retain some relations that must hold true at the exact solving of the problem. As a result, the theory is built in terms of the correlation functions and the vertex parameters obeying the self-consistent set of equations. In Refs. [23,24] a single vertex parameter was chosen so as to satisfy the sum rule. One vertex parameter turned out to be quite enough to describe quantitatively the thermodynamics of 1D and 2D on a square and triangular lattices ferromagnets in zero field.

When employing the above-mentioned scheme to the spin systems in an external magnetic field, along with the correlators we have to determine at least three additional functions of temperature and field: two vertex parameters and magnetization. To do this we need three relations two of which are quite evident from the properties of the spin-1/2 operator

$$\langle (S^z)^2 \rangle = \frac{1}{4}, \quad \langle S^z \rangle = \frac{1}{2} - \langle S^- S^+ \rangle, \quad (1)$$

where angular brackets denote thermodynamic averaging. The choice of the third condition is not so apparent. In Ref. [29] a second-order Green function scheme was applied to HFM chain and HFM on a square lattice. As the third condition the authors of Ref. [29] used the exact representation of the internal energy through the transverse Green function [30].

The aim of the present work is to calculate the thermodynamic functions of HFM on a triangular lattice in an external magnetic field using a second-order Green function formalism. As compared to a chain and square lattice [12,13,14,15,16] HFM on a triangular lattice in a magnetic field is much less investigated. For this case high temperature series expansion (HTSE) [31] low
temperature asymptotics for the magnetization calculated within the spin wave approximation \[24-25\], temperature dependences of the magnetization found by quantum Monte Carlo simulations (QMC) on a 16 x 16 cluster\[22\] and some results obtained by the renormalization group technique\[23\] (RGT) are known. However, none of these approaches gives a complete description of the thermodynamics in the whole temperature and field ranges, and a second-order Green function method is expected to fill the gap in our knowledge.

In the present work we show that this method is more effective when the conditions determining the magnetization and vertex parameters result from the fundamental principles. Clearly the relations \[1\] are just of this kind. It is equally important to retain the analytical properties\[23,24,21\] of the Green functions in the approximate approach. Such a requirement for the transverse commutator Green function provides a basis for the third condition in our theory. Note also that by appropriate choice of variables the set of self-consistent equations for the correlators, vertex parameters, and magnetization can be written in a universal form suited not only for a triangular lattice but also for a chain and square lattice. A good agreement of our results obtained for the three types of lattices with the corresponding data available from literature confirms the efficiency of the used scheme.

In Sec. II, the statement of the problem is formulated and the self-consistent set of equations for the correlators, magnetization, and vertex parameters is derived. In Sec. III, the proposed scheme is applied to HFM on a chain, square and triangular lattices. The obtained results are compared with the corresponding data found within other methods. Some concluding remarks are made in Sec. IV.

II. STATEMENT OF THE PROBLEM

The Hamiltonian of the system is given by

\[ H = -J \sum_{\ell, \delta} S_{\ell} S_{\ell + \delta} - h \sum_{\ell} S_{\ell}^z, \] (2)

where \( S_{\ell} \) is the spin-half operator at site \( \ell \), \( \delta \) is a vector connecting nearest neighbors, \( J > 0 \) is an exchange integral, \( h = 2 \mu B \), \( \mu \) is the magnetic moment of a particle, \( B \) is an external magnetic field.

To calculate spin-spin correlators, it is necessary to find two retarded commutator single-particle Green functions: \( \langle S_{\ell}^z S_{\ell}^{\sigma} \rangle \), \( \langle S_{\ell}^z S_{\ell}^{-\sigma} \rangle \) (\( \sigma = \pm \)). We write down equations of motion for these two functions and make the decoupling of the higher Green functions on the second step according to the scheme proposed in Ref.\[39\]

\[ S_{\ell}^z S_{\ell}^{\sigma} S_{\ell}^{-\sigma} = \alpha_{\perp} \langle S_{\ell}^z S_{\ell}^{\sigma} \rangle S_{\ell}^{-\sigma} + \langle S_{\ell}^z S_{\ell}^{-\sigma} \rangle S_{\ell}^{\sigma}, \]
\[ S_{\ell}^z S_{\ell}^{\sigma} S_{\ell}^z = \alpha_{\perp} \langle S_{\ell}^z S_{\ell}^{\sigma} \rangle S_{\ell}^z, \quad S_{\ell}^z S_{\ell}^{\sigma} S_{\ell}^{-\sigma} = \alpha_{\perp} \langle S_{\ell}^z S_{\ell}^{-\sigma} \rangle S_{\ell}^z, \]
\[ i \neq j \neq l, \quad i \neq l, \] (3)

where \( \alpha_{\perp} \) and \( \alpha_{\parallel} \) are the vertex parameters.

After a number of manipulations we finally obtain for the time-space Fourier component \( \langle S_{\ell}^z S_{\ell}^{-\sigma} \rangle \)

\[ \langle S_{\ell}^z | S_{\ell-k}^z \rangle \omega = \frac{Jc_1 \gamma_0}{4\pi} \frac{1 - \Gamma_k}{\omega^2 - (\omega_k^z)^2}, \] (4)

where

\[ (\omega_k^z)^2 = \frac{J^2 \gamma_0}{2} (1 - \Gamma_k) \left[ \Delta_z + \gamma_0 \tilde{c}_1 (1 - \Gamma_k) \right], \] (5)
\[ \Delta_z = 1 + \tilde{c}_2 - (\gamma_0 + 1) \tilde{c}_1. \] (6)

Here the following correlation functions have been introduced

\[ c_1 = 2 \langle S_{\ell}^z S_{\ell}^{-\sigma} \rangle, \quad c_2 = 2 \sum_{\delta} \langle S_{\ell}^{\delta} S_{\ell + \delta}^{\sigma} \rangle, \quad \tilde{c}_1, \tilde{c}_2 = \alpha_{\perp} c_{1,2}. \] (7)

The primed sum indicates that the term with \( \delta = \delta' \) is omitted in it. The structure factor \( \Gamma_k \) is defined as

\[ \Gamma_k = \frac{1}{\gamma_0} \sum_{\delta} \exp(ik\delta), \] (8)

where the coordination number \( \gamma_0 \) is equal to 2 for a chain, 4 for a square lattice, and 6 for a triangular lattice. Fourier transform \( \langle S_{\ell}^z S_{\ell-k}^{-\sigma} \rangle \omega \) can be written as

\[ \langle S_{\ell}^z | S_{\ell-k}^{-\sigma} \rangle \omega = \frac{1}{2\pi} \sum_{i=1,2} \frac{A_{i,k}^\perp}{\omega - \Omega_{i,k}^\perp}. \] (9)

Here

\[ \Omega_{i,k}^\perp = h\sigma + (-1)^i \omega_k^\perp, \] (10)
\[ (\omega_k^\perp)^2 = \frac{J^2 \gamma_0}{2} (1 - \Gamma_k) \left[ \Delta_{\perp} + \gamma_0 \tilde{b}_1 (1 - \Gamma_k) \right], \] (11)
\[ \Delta_{\perp} = 1 + \tilde{b}_2 - (\gamma_0 + 1) \tilde{b}_1, \] (12)
\[ A_{i,k}^\perp = \sigma \langle S^z \rangle + (\omega_k^\perp)^2 \frac{(-1)^{i-1} J \tilde{b}_1 \gamma_0}{2\omega_k^\perp} (1 - \Gamma_k), \] (13)

where \( \langle S^z \rangle \) is the magnetization. Due to the presence of the external magnetic field, \( \langle S^z \rangle \) is nonzero at any finite temperature.

The correlation functions entering Eqs. \(11-13\) are defined by

\[ b_l = \frac{a_l + c_l}{2}, \quad \tilde{b}_l = \alpha_{\perp} b_l, \quad l = 1, 2, \] (14)
\[ a_1 = 4 \langle S_{\ell}^z S_{\ell}^{\delta} \rangle, \quad a_2 = 4 \sum_{\delta} \langle S_{\ell}^{\delta} S_{\ell + \delta}^{\delta} \rangle. \] (15)
The Green functions look formally the same for three above-mentioned types of lattices. Such universal form has been possible to obtain, because instead of the usual correlators describing correlations between spins which are two steps along the translation vector \( \mathbf{\delta} \) apart, we use linear combinations \( c_2 \) and \( c_3 \) defined by Eq. (7) and Eq. (15). The physical meaning of these combinations depends on the lattice type. For a chain, \( c_2 \) and \( c_3 \) are the next nearest neighbor correlators. For a square lattice these combinations contain the correlation functions between the spin at site \( f \) and spins from the second and third coordination spheres, and for a triangular lattice these combinations in addition to the higher order correlators include also \( c_1 \) and \( c_2 \). For a chain and square lattice Green functions (4) and (9) coincide with those found in Ref. [39].

Using the spectral relation, we have

\[
a_1 = \frac{J_{c_1}}{N} \sum_k \Gamma_k g_k + 4\langle S^z \rangle^2,
\]

\[
a_2 = \frac{J_{c_1}}{N} \sum_k (\gamma_0 \Gamma_k - 1) g_k + 4(\gamma_0 - 1)\langle S^z \rangle^2,
\]

\[
a_1 = \frac{1}{\alpha_\perp N} \sum_k \Gamma_k p_k,
\]

\[
a_2 = \frac{1}{\alpha_\perp N} \sum_k (\gamma_0 \Gamma_k^2 - 1) p_k,
\]

where

\[
g_k = \frac{\gamma_0}{\omega_k^\perp} (1 - \Gamma_k) \coth \left( \frac{\beta \omega_k^\perp}{2} \right),
\]

\[
p_k = \frac{2\alpha_\perp \langle S^z \rangle \sinh (\beta h) - J\tilde{b}_1 \gamma_0 (1 - \Gamma_k) \sinh (\beta \omega_k^\perp)}{\cosh (\beta h) - \cosh (\beta \omega_k^\perp)},
\]

\[
ge_k = \frac{\gamma_0}{\omega_k^\perp} (1 - \Gamma_k) \coth \left( \frac{\beta \omega_k^\perp}{2} \right),
\]

\[
p_k = \frac{2\alpha_\perp \langle S^z \rangle \sinh (\beta h) - J\tilde{b}_1 \gamma_0 (1 - \Gamma_k) \sinh (\beta \omega_k^\perp)}{\cosh (\beta h) - \cosh (\beta \omega_k^\perp)},
\]

\[
N \text{ is the total number of sites, } \beta = 1/T. \text{ Eq. (16) represents the set of equations for the correlation functions } c_1 \text{ and } c_2. \text{ Along with these correlators, the set (16) contains the parameters } \alpha_\perp, \alpha_\parallel, \gamma_0, \text{ and magnetization } \langle S^z \rangle \text{ to be also determined.}
\]

The vertex parameters are chosen so as to satisfy the sum rules

\[
4\langle (S_f^1)^2 \rangle = 1, \quad 2\langle S_f^1 S_f^\sigma \rangle = 1 + 2\sigma \langle S^z \rangle,
\]

which using (17) can be written as

\[
\frac{J_{c_1}}{N} \sum_k g_k + 4\langle S^z \rangle^2 = 1, \quad \alpha_\perp = \frac{1}{N} \sum_k p_k.
\]

Finally, in order to close the system (16), (18) we need one more equation. It can be found from the following consideration. It is known [28,30] that a commutator Green function must not have any pole at \( \omega = 0 \). Clearly Green function (4) does not have such pole. A different situation arises with Green function (9). When \( \omega = 0 \) its denominator is equal to zero at \( k = k_0 \) with wave vector \( k_0 \) satisfying the equation

\[
h = \omega_{k_0}^\perp.
\]

Thus, the numerator of Green function (9) must also vanish at \( k = k_0 \), for otherwise this function would have a pole. From this condition we get the equation for \( \langle S^z \rangle \)

\[
\langle S^z \rangle = \frac{Jb_1 \gamma_0}{2\omega_{k_0}^\perp} (1 - \Gamma_{k_0}).
\]

Note, that in calculating the anticommutator transverse Green function, the condition (20) appears automatically without any special assumptions (see also Ref. [51]).
for $b_1$, $\Delta_z$, and $\Delta_{\perp}$

$$1 = \frac{Jc_1}{N} \sum_k g_k + 4 \langle S^z \rangle^2,$$

$$2b_1 = \alpha_\perp c_1 \left[ 1 - \frac{J}{N} \sum_k (1 - \Gamma_k) g_k \right] + \alpha_\perp,$$

$$\Delta_{\perp} = 1 - \alpha_\perp + \frac{\alpha_\perp}{2\alpha_z} (\Delta_z - 1) + \frac{J\alpha_\perp c_1}{2N} \sum_k (1 - \Gamma_k) (1 - \gamma_0 \Gamma_k) g_k. \quad (23)$$

The values $c_1$, $\alpha_\perp$, and $\langle S^z \rangle$ can be expressed through $b_1$, $\Delta_z$ and $\Delta_{\perp}$ according to $[16]$, $[18]$ and $[22]$. For $\alpha_z$ with the help of Eqs. $[6]$ and $[7]$ we have

$$\alpha_z = \frac{1 - \Delta_z}{(\gamma_0 + 1) c_1 - c_2}. \quad (24)$$

It is easy to see that the replacement $h \to -h$ changes the sign of the magnetization and does not change the correlation functions and vertex parameters. Owing to condition $[22]$, Eq. $[17]$ and thereby Eqs. $[16]$, $[18]$ have no singularities. At $h = 0$ the system $(23)$ reduces to that found in Refs. $[33,38]$

The internal energy $E$ per site is given by

$$E = -\frac{J\gamma_0}{8} (2c_1 + a_1) - h\langle S^z \rangle. \quad (25)$$

$$1 - \frac{1}{J\gamma_0 \langle S^z \rangle N} \sum_k \frac{Jb_1 \gamma_0 (1 - \Gamma_k) \sinh (\beta h) - 2 \langle S^z \rangle \omega_k^+ \sinh (\beta \omega_k^+)}{\cosh (\beta h) - \cosh (\beta \omega_k^+)} \equiv R \quad (27)$$

The quantity $R$ is a function of field and temperature. Due to Eq. $[22]$ expression $[27]$ is singularity-free. It is evident that the closer $R$ to zero, the better the approximation. Thus, the condition $|R| \ll 1$ can serve as another criterion of the approximation efficiency. Below, in discussing the results we will calculate $R(h,T)$ and check the fulfillment of this criterion for the proposed scheme.

III. RESULTS AND DISCUSSION

In the general case the set of equations $(23)$ can be solved only numerically. In limiting cases analytical results could be obtained. At $T = 0$ the system $(23)$ gives correct values for the sought quantities

$$\langle S^z \rangle = \frac{1}{2}, \quad c_{1,2} = 0, \quad a_1 = 1, \quad a_2 = \gamma_0 - 1. \quad (28)$$

The same solution is also true for finite temperatures at $h \to \infty$.

In the high temperature limit $(J,h \ll T)$ the system $(23)$ can be solved by expanding in $1/T$. Restricting our consideration to the second order in $x = J/(4T)$ and $y =$
we obtain the following asymptotic expressions

\[
\begin{align*}
    c_{1}^{a_{s}} &= x + \frac{x^2}{4} (\gamma_0^2 - 6\gamma_0 + 4), \\
    c_{2}^{a_{s}} &= \frac{x}{4} \left[ (\gamma_0 - 2)(\gamma_0 - 4) - x(\gamma_0^2 - 14\gamma_0 + 20) \right], \\
    a_{1}^{a_{s}} &= c_{1}^{a_{s}} + y^2, \\
    a_{2}^{a_{s}} &= c_{2}^{a_{s}} + (\gamma_0 - 1)y^2, \\
    \langle S^z \rangle^{a_{s}} &= \frac{y}{2} (1 + \gamma_0 x), \\
    a_{z}^{a_{s}} &= a_{z}^{a_{s}} = 1 - \frac{x}{3}.
\end{align*}
\]

(29)

For the heat capacity \( C = dE/dT \) to the third order in \( x \) and \( y \) we get

\[
C^{a_{s}} = \frac{3\gamma_0 x^2}{2} \left[ 1 + \frac{x}{2} \left( \gamma_0^2 - 6\gamma_0 + 4 \right) \right] + y^2 (1 + 3\gamma_0 x).
\]

(30)

The expressions for the magnetization and heat capacity coincide with those obtained by the direct high temperature series expansion. As it follows from Eq. (29) the field-dependent terms in expansions for \( c_{l} \) occur in the fourth or higher order in \( 1/T \).

We will demonstrate the efficiency of the proposed scheme applying it to the 1D HFM and HFM on a square lattice. The main attention will be paid to low fields, because it is this region that is the most difficult for the adequate description within approximate methods.

A. One-dimensional Heisenberg model

In this subsection we consider 1D HFM. Figs. 1-3 demonstrate the magnetization, susceptibility \( \chi = \partial \langle S^z \rangle / \partial h \), and heat capacity vs temperature at low fields obtained within our approach. In calculating the thermodynamic functions on clusters, we use the periodic boundary conditions. The corresponding dependences found in Ref. 39 by Bethe ansatz (BA) and GFAM for an infinite chain and by the exact diagonalization (ED) for a cluster of 16 sites are also shown for comparison.

For the magnetization and susceptibility our method yields a good agreement with the exact results in the whole temperature range. The positions of the maxima in our curves for \( \chi(T) \) coincide perfectly with those found within the exact methods and only a small difference in the peak heights is observed.

At low fields the exact methods indicate the dependence of the thermodynamic functions on the chain length. As it is seen from Figs. 1, 2 at \( h/J = 0.005 \) the curves \( \langle S^z(T) \rangle \) and \( \chi(T) \) obtained by ED for the finite-sized chain differ substantially from those found by BA for the infinite system. Our method gives a proper description of this effect. At higher fields (Figs. 1, 3) where the ED and BA results coincide our dependences for \( N = 16 \) and \( N \rightarrow \infty \) also coincide and show a good fit to the exact data.

As it can be seen from Fig. 3 there is a certain disagreement between the heat capacities obtained within the exact and approximate methods at low fields. This result is quite understandable. Indeed, a similar scheme applied to 1D HFM at \( h = 0 \) gives in the low temperature region sufficiently different run of the heat capacity than the exact solution. Nevertheless, even at \( h/J = 0.1 \) our theory not only gives the correct position of the maximum but also reproduces a specific bend in the curve \( C(T) \) at \( T/J \sim 0.3 \). The agreement between \( C(T) \) calcu-
FIG. 3: Temperature dependences of the heat capacity for 1D HFM at $h/J = 0.1$. The infinite system: present theory (solid), BA\cite{BA} (■), GFAM\cite{GFAM} (dotted). The cluster: ED\cite{ED} (○). The inset shows $C(T)$ at low fields $h/J=0.001, 0.005, 0.01, 0.025, 0.05, 0.075, 0.1$ (from bottom to top).

lated within our scheme and found by the exact methods becomes better with increase in field. The inset in Fig. 3 illustrates a double-peak structure of the heat capacity that within our method is identified at $0 < h/J < 0.045$. A similar structure of $C(T)$ at low fields was first obtained in Ref.\cite{Ref39}.

We calculated the entropy for 1D HFM. It turned out that the higher is the field the closer is the limiting value $S(\infty)$ to $\ln 2$. For example, at $h/J = 0.05$ the entropy is $S(\infty) \simeq 0.631$ and at $h/J = 1$ it is $S(\infty) \simeq 0.687$. The quantity $R(h, T)$ was also found. At low and high temperatures it is practically equal to zero, so that the Green function \cite{Green} and correlators calculated within our method may be considered as satisfying Eq. \cite{Eq26}. At a given field in the intermediate temperature range where the correlators vary rapidly the quantity $R$ is at maximum. At $h/J = 0.05$ the maximum value of $R$ is $\sim 0.027$ whereas at $h/J = 1$ it does not exceed 0.006. With increase in $h/J$ the quantity $R$ decreases and the difference between results obtained by the exact and approximate methods vanishes.

B. HFM on a square lattice

Now we proceed to the HFM on a square lattice. Fig. \ref{fig4} demonstrates the magnetization as a function of temperature at $h/J = 0.1$ and 0.4 for $4 \times 4$ and $32 \times 32$ square lattice clusters together with QMC\cite{QMC} ED\cite{ED} and GFAM\cite{GFAM} data. The inset shows the magnetizations for the $32 \times 32$ cluster at $h/J = 0.05, 0.1, 0.2, 0.32, 0.4$ found

FIG. 4: Temperature dependences of the magnetization for HFM on a square lattice at $h/J = 0.1$ and 0.4 (from left to right). The infinite system: present theory (solid), QMC\cite{QMC} (▲) and GFAM\cite{GFAM} (dotted). The $4 \times 4$ cluster: present theory (dashed) and ED\cite{ED} (○). The inset shows $\langle S^z \rangle$ vs $T/J$ at $h/J=0.05, 0.1, 0.2, 0.32, 0.4$ (solid) in comparison with QMC\cite{QMC} (▲) and HTSE\cite{HTSE} (dashed) (from left to right).

FIG. 5: Temperature dependences of the susceptibility for HFM on a square lattice at $h/J = 0.2, 0.4, 1.0$ (from top to bottom). The infinite system: present theory (solid), HTSE\cite{HTSE} (dash-dotted), and GFAM\cite{GFAM} (dotted). The $4 \times 4$ cluster: present theory (dashed) and ED\cite{ED} (○).
FIG. 6: Correlation functions $a_1$ (a) and $c_1$ (b) for HFM on a square lattice at $h/J = 0.1$ and 0.4 (from left to right). The infinite system: present theory (solid) and GFAM (dotted). The $4 \times 4$ cluster: present theory (dashed) and ED (◦).

within the present method, QMC[31] and HTSE[43] The comparison between our results and HTSE is possible, because at these values of field the magnetizations for the $32 \times 32$ cluster proved[31] to be identical to those for the infinite lattice. It is seen that the temperature dependences of $\langle S^z \rangle$ obtained within our approach are in good agreement with the exact results. The proposed scheme reproduces correctly the dependence of $\langle S^z \rangle$ on the size of the system as well. The difference between the present results and GFAM in Fig. 4[31][39] as well as $a_1$ and $c_1$ at $h/J = 0.1$ and 0.4 calculated for the $4 \times 4$ cluster as well as for the infinite lattice are presented in Fig. 6. The ED and GFAM results are added for comparison. At low fields a clearly defined dependence on the size of the system is seen. Our results for the infinite lattice differ noticeably from GFAM. For the $4 \times 4$ cluster a good agreement with the dependences calculated by ED is observed.

The limiting value of entropy for the HFM on the square lattice is $S(\infty) = 0.651$ at $h/J = 0.05$ and $S(\infty) = 0.684$ at $h/J = 1$, which is very close to the exact value ln 2. The maximum value of $R$ is $\simeq 0.058$ at $h/J = 0.05$ and $\simeq 0.014$ at $h/J = 1$.

Thus, the results of subsections A, B show, that the theory based on the correct accounting for the analytical properties of Green functions gives an adequate description of the thermodynamic functions for the systems under consideration in the wide field and temperature range.

C. HFM on a triangular lattice

In this subsection we consider HFM on a triangular lattice in an external magnetic field with peculiar attention concentrated on small and intermediate fields. Fig. 7[32] represents the temperature dependences of the magnetization at different values of $h/J$. It is seen that our results agree closely with HTSE[43] up to the point of HTSE applicability, whereas the RPA curves coincide with HTSE only at relatively high temperatures. In the intermediate temperature range the RPA results differ sufficiently from ours even at $h/J = 1.5$ reproducing the temperature behavior of $\langle S^z \rangle$ only qualitatively. We have also calculated the magnetization at low temperatures using the renormalization group technique. The results obtained by both our approaches are in good agreement.

Fig. 8 illustrates the temperature behavior of the susceptibility. Analysis shows that with increase in field the maximum in $\chi(T)$ decreases and shifts to higher temperatures. At $h/J \geq 0.1$ the height of the maximum as a function of $h/J$ with a great degree of accuracy is described by a power law

$$\chi_{\text{max}} = a \left( \frac{h}{J} \right)^b, \quad a = 0.1696, \quad b = -0.8634. \quad (31)$$

Temperature dependences of the correlation functions $a_1$ and $c_1$ at different $h/J$ are shown in Fig. 9. Beginning
FIG. 7: Temperature dependences of the magnetization for HFM on a triangular lattice at $h/J = 0.1, 0.3, 0.5, 0.7, 1.0, 1.5$ (from left to right). The present theory (solid), HTSE\textsuperscript{43} (dashed), RGT (thin lines), and RPA (dotted).

FIG. 8: Temperature dependences of the susceptibility for HFM on a triangular lattice at $h/J = 0.2, 0.4, 1.0$ (from top to bottom). The present theory (solid), HTSE\textsuperscript{43} (dashed), and RPA (dotted).

FIG. 9: Correlation functions $a_1$ (a) and $c_1$ (b) for HFM on a triangular lattice at $h/J = 0.1, 0.3, 0.5, 0.7, 1.0, 1.5$ (from left to right). The present theory (solid) and RPA (dotted). Thin lines correspond to $h = 0$.

with $T/J \sim 0.5$ the RPA results differ from ours sufficiently. It is easy to verify that at $T \gg J$ the correlator $a_1$ calculated within RPA to the first approximation in $J/T$ is negative and equal to $-J/(4T)$. Thus, almost at all temperatures RPA fails to describe correctly the correlation functions and, hence, the energy and heat capacity.

Fig. 10 demonstrates the temperature dependences of the heat capacity $C(T)$ in comparison with HTSE\textsuperscript{43} and RPA. It is seen that our results are in good agreement with HTSE. With increase in field the position of the maximum in the curve $C(T)$ shifts to higher temperatures and its value $C_{tr m}$ first increases rapidly and then decreases. A similar behavior occurs for the heat capacity maximum $C_{sq m}$ on a square lattice. Maximum values $C_{sq m}$ and $C_{tr m}$ vs field are illustrated in Fig. 11. Field dependences of the maximum positions for the square and triangular lattices are shown in the inset. At $h/J \leq 1$ both $C_{tr m}(h/J)$ and $C_{sq m}(h/J)$ can be approximated by a
FIG. 10: Temperature dependences of the heat capacity for HFM on a triangular lattice at $h/J = 0.1, 0.5, 1.0, 1.5$ (from left to right). The present theory (solid), HTSE$^{43}$ (dashed), and RPA (dotted). Thin lines correspond to $h = 0$.

FIG. 11: Field dependences of the heights and positions of the heat capacity maxima for HFM on square and triangular lattices. The function

$$C_m = \frac{ax}{b + x}, \quad x = \frac{h}{J},$$

with

$$a = \begin{cases} 0.5136, & \text{square;} \\ 0.5254, & \text{triangular.} \end{cases} \quad b = \begin{cases} 0.0239, & \text{square;} \\ 0.0189, & \text{triangular.} \end{cases}$$

At higher fields ($h/J \geq 1.4$) the maximum values decrease linearly

$$C_m = Ax + B,$$

$$A = \begin{cases} 0.00693, & \text{square;} \\ 0.0248, & \text{triangular.} \end{cases} \quad B = \begin{cases} 0.5118, & \text{square;} \\ 0.5468, & \text{triangular.} \end{cases}$$

Since $C_m^{\text{sq}}$ decreases slower than $C_m^{\text{tr}}$, the inequality $C_m^{\text{tr}} > C_m^{\text{sq}}$ valid for low fields changes into the opposite one at $h/J \geq 2$.

Let us consider now the dependence of the thermodynamic functions on the cluster size $L \times L$. It is interesting to determine the linear size $L_0$ corresponding to the thermodynamic limit at a given magnetic field. This quantity is important, for example, on using such methods as Monte Carlo and exact diagonalization, when a knowledge of an optimal cluster size makes it possible to obtain the thermodynamic functions of the infinite system within a reasonable volume of calculations. The dependence of the thermodynamic functions on $L$ is also of practical interest, because of the isle structure of $^3$He layers at some coverages.$^{24}$

Fig. 12 displays temperature dependences of the heat capacity at $h/J = 0.1$ and 1 for different cluster sizes $L$ up to $L_0$. It is seen that with decrease in $L$ maximum in the curve $C(T)$ decreases and shifts to higher temperatures. At small $L$ and very low fields a second maximum arises on the low temperature part of the heat capacity. A similar additional maximum resulting from the finite size of the system was found by ED for the $4 \times 4$ square lattice in Ref. $^{39}$ This result is also reproduced by our calculations.

Fig. 13 shows dependences $L_0(h/J)$ for the square and triangular lattices. At $h/J < 0.2$ even small variation in
FIG. 13: Dependences $L_0(h/J)$ for triangular ($\triangle$) and square (■) lattices.

FIG. 14: Temperature dependences of the magnetization for $16 \times 16$ triangular lattice HFM at $h/J = 0.429, 0.214, 0.0429, 0.0171, 6.09 \times 10^{-3}, 2.76 \times 10^{-3}, 4.29 \times 10^{-4}$ (from top to bottom): present theory (solid) and QMC[44] (symbols).

field leads to a sufficient change in $L_0$. As the field increases this dependence weakens, so that beginning with $h/J \sim 0.2$ rather small-sized clusters are appropriate for the numerical simulations of the real infinite systems.

Temperature dependences of the magnetization for a $16 \times 16$ triangular lattice together with the corresponding QMC data[44] are shown in Fig. 14. Our results agree well with QMC.

Now we check up the two criteria outlined in Sec. II, as applied to the triangular lattice HFM. The limiting value of the entropy is equal to 0.708 and 0.713 at $h/J = 0.05$ and 1, respectively, which slightly exceeds $\ln 2$. At low and high temperatures the function $R(T, h)$ is close to zero as it was for HFM on the chain and square lattice. At fixed field in the intermediate temperature region $R(T, h)$ has a maximum, whose height decreases as $h/J$ increases. The maximum value of $R$ is $\sim 0.094$ at $h/J = 0.05$, whereas at $h/J = 1$ it does not exceed 0.046.

IV. SUMMARY

The thermodynamics of the low dimensional spin-$1/2$ Heisenberg ferromagnets in an external magnetic field is investigated within a second-order two-time Green function formalism in the wide temperature and field range. The self-consistent set of equations for the correlation functions, vertex parameters and magnetization is obtained in the universal form appropriate for the description of low dimensional HFM on a chain, square and triangular lattices. The fundamental point of our consideration is the account of the correct analytical properties for the approximate transverse commutator Green function, from which the equation for the magnetization follows. This enables us to extend the range of adequate description for the HFM thermodynamics to lower fields as compared to the scheme proposed in Ref. 39.

The thermodynamics of a triangular lattice HFM in a magnetic field is studied within a second-order Green function formalism for the first time. The temperature dependences of the magnetization, susceptibility, correlation functions, and heat capacity at different values of the magnetic field are calculated and analyzed in detail. For square and triangular lattices the positions and heights of the heat capacity maxima vs field are obtained. The dependences of the thermodynamic functions of the 2D HFM on the cluster size are investigated. For both types of lattices the cluster sizes corresponding to the thermodynamic limit are found as functions of field.

The temperature and field dependences for the thermodynamic functions calculated within our scheme are in close agreement with the corresponding results obtained by Bethe ansatz, quantum Monte Carlo simulations, high temperature series expansion, and exact diagonalization. Thus, we can conclude that the scheme used in this paper provides a good quantitative description for the thermodynamics of the low dimensional HFM in an external magnetic field on the three considered types of lattices for infinite as well as for finite-sized systems.
