Feasibility of self-sampling and human papillomavirus testing for cervical cancer screening in First Nation women from Northwest Ontario, Canada: a pilot study

Ingeborg Zehbe, Helle Moeller, Alberto Severini, Bruce Weaver, Nicholas Escott, Crystal Bell, Sandra Crawford, Diane Bannon, Natalie Paavola

ABSTRACT

Background: The incidence of cervical cancer is up to sixfold higher among First Nation women in Canada than in the general population. This is probably due to lower participation rates in cervical cancer prevention programmes.

Objective: To raise screening participation in this underserved population by launching an alternative approach to (Pap)aniconoi testing in a clinic—namely, vaginal self-sampling followed by human papillomavirus (HPV) diagnostics.

Methods: Good relationships were established with a First Nation community of the Northern Superior region in Northwest Ontario, and then 49 community women, aged 25–59, were recruited, who provided a vaginal self-sample and answered a questionnaire. Frequency distributions and cross-tabulations were used to summarise the data. Associations between categorical variables were assessed using the $\chi^2$ test of association, or the Goodman–Kruskal $\gamma$ if both variables had ordered categories. Self-collected samples were tested for integrity and HPV using optimised molecular biological methods.

Results: The majority of participants (87.2%) were amenable to future HPV screening by self-sampling. This finding was independent of age, educational level and a previous history of abnormal Pap tests. Interestingly, the preferred way to learn about sexual health remained through interaction with healthcare professionals. As defined by the presence of a housekeeping gene, self-sample integrity was high (96%). Using polymerase chain reaction-based Luminex typing, 28.6% of the participating women were HPV-positive (ie, with either a low- or high-risk type) and 16.3% were infected with a high-risk type such as HPV16.

Conclusion: In this pilot study of First Nation women, self-sampling and HPV testing was well received and self-sample quality was excellent. A larger survey to be conducted in other Northern Superior communities in Northwest Ontario will determine whether this approach could become a viable screening strategy for First Nation women.

ARTICLE SUMMARY

Article focus

- Independent international studies have shown that self-sampling for cervical screening is safe and equally reliable as sampling by a health professional.
- Self-sampling has been reported to increase screening compliance for women who have never or not regularly been screened.
- To date, self-sampling has not been studied in First Nation (aboriginal) women in Canada, an underserved population in whom cervical cancer is up to six times higher than in the general population.

Key messages

- First Nation women participating in this pilot study were amenable to future HPV screening by self-sampling. This finding was independent of age, educational level and a previous history of abnormal Pap tests.
- Interestingly, the preferred way to learn about sexual health remained through interaction with healthcare professionals. As defined by the presence of a housekeeping gene, self-sample integrity was high (96%). Using polymerase chain reaction-based Luminex typing, 28.6% of the participating women were HPV-positive (ie, with either a low- or high-risk type) and 16.3% were infected with a high-risk type such as HPV16.

Strengths and limitations of this study

- Good relations with the largest First Nation community in Northwest Ontario have been established and our pilot study forms a basis for promoting cervical cancer screening in other First Nation communities in that region.
- A larger study is needed to validate our findings and to achieve good statistical power.

Zehbe I, Moeller H, Severini A, et al. BMJ Open 2011;1:e000030. doi:10.1136/bmjopen-2010-000030
INTRODUCTION

Cervical cancer is among the top three cancers affecting women worldwide and the third most common cancer in Canada among women aged 20–49. Aboriginal populations appear to be particularly affected by this disease. In Canada, cervical cancer is up to sixfold higher in First Nation women than in the general population in the Northwest Territories, Manitoba and Ontario. Similarly, aboriginal women from Australia and the USA have a higher cervical cancer prevalence than the general population in those countries.

Most women who develop cervical cancer have been infrequently or never screened, yet such screening is crucial for early detection of precancerous lesions. Accessing health information and preventive medical services can be challenging for First Nation women in their communities are generally rural and remote, transportation is a limiting factor and culturally appropriate, on-site health and educational services may be inadequate. These challenges (as well as the lack of an electronic database to identify seldom or never screened Ontario women) probably contribute to irregular participation of First Nation women in cervical screening in comparison with other Canadian women.

Lack of accessible or appropriate screening facilities could be overcome by offering a screening test based on self-collection. Indeed, the Canadian Aboriginal Health Organization suggested that HPV testing based on self-sampling may be a good alternative to (Pap)anicolaou testing to increase participation among First Nation women. In addition, a comprehensive review by the International Agency for Research on Cancer Working Group concluded that human papillomavirus (HPV) testing is a justifiable strategy for cervical cancer prevention. Self-collection of vaginal samples for HPV testing has been investigated as a potential cervical screening method in several populations, with good uptake (reviewed by Stewart et al and by Huynh et al and references therein). Two Swedish studies found that, among women who had not been screened for more than 6 years, 32–58% participated in self-sampling. Similar findings have been obtained in a recent Canadian study, suggesting that Caucasian women who do not participate in cervical cancer screening programmes may be willing to provide a self-collected specimen instead. Furthermore, self-collection has been observed to be as reliable as sampling carried out by a doctor for the detection of high-risk HPV associated with an increased risk of cervical cancer.

A study on cervical cancer screening uptake based on self-sampling and HPV testing among First Nation women has never been conducted in Ontario. Before beginning a large investigation in 10 Northern Superior communities in Northwest Ontario (box 1), we conducted a pilot study with 49 First Nation women in the largest of these communities. Our approach was based on convenient self-sampling and sensitive HPV testing, rather than (Pap)anicolaou screening. To assess the feasibility of this alternative method we used a questionnaire in which demographics and cervical cancer knowledge, self-sampling and sexual health were investigated. Sample adequacy and HPV testing methods were also evaluated.

METHODS

Participating First Nation community

Fort William First Nation (FWFN), the community that participated in our pilot study, is situated near Thunder Bay on the northern shore of Lake Superior in Northwest Ontario, Canada. FFWN was created in 1853, as a result of the 1850 Robinson-Superior Treaty. With a total of 1798 individuals registered, of whom 832 live on-reserve, FFWN is the largest of the Northern Superior communities (box 1). The mean population of all communities is 313 (range 70–832). We chose these communities for our investigation since they are part of one strategic region of the Anishinabek Nation inhabiting the northern shore of Lake Superior from Pigeon River to Batchawana Bay. They are under the healthcare portfolio held by the Regional Grand Chief in FFWN.

Approvals

After a meeting with the band council a research agreement, identifying potential benefits for the participants’ community, data ownership and plans for dissemination and publication of the results, was signed in September 2009 by FFWN Grand Chief Peter Collins. The agreement adhered to guidelines formulated by the First Nations Information Governance Committee through ownership, control, access and possession. The study was also approved by the local research ethics board of Thunder Bay Regional Health Sciences Centre (TBRHSC REB#2009125). The on-site Dilico family health team (DFHT) agreed to recruit participants and provide feedback about the study approach.

Participant recruitment

A DFHT nurse practitioner (project nurse) served as primary contact for the participating women. To enrol approximately 50 volunteers, recruitment and

Self-sampling and HPV testing in First Nation women

information dissemination was carried out between 16 November and 18 December, 2009 through a community meeting with an information poster; flyers posted in public places within the community; flyers sent to all community households through the weekly Band newsletter and flyers distributed at parenting workshop nights through the Band office and DFHT staff. Women were not approached individually. All participants automatically took part in incentive draws for five, CAD$100 grocery certificates.

Participant eligibility
Eligibility for our pilot study required that participants: were female; self-reported First Nation ethnicity; registered in FWFN; were aged 25–59 years and had a command of the English language. For safety reasons, women who knew they were pregnant or menstruating were excluded. Women were enrolled from age 25 rather than age 30 because Canadian First Nation women exhibit earlier onset of cervical cancer than the general population and HPV testing is recommended at an earlier age.1,23

Protocol
Eligible women who wanted to participate in the pilot study contacted DFHT staff. The research nurse provided information orally and through the informed consent form, which was explained to, and signed by, the volunteer before taking a self-sample. After taking the self-sample, the questionnaire was answered, numbered and sent to the research team in a sealed envelope. Participants could choose whether or not they wanted their test results sent to their healthcare provider (HCP) or to their homes, or to both.

Self-sampling
The project nurse provided each participant with a sterile, plain polyester Dacron swab15 and transportation tube (Copan Diagnostics Sterile Plain Swab; licensed in Canada by Inverness Medical: #552C). Swabs were sent at ambient temperature in the transportation tube to the National Microbiology Laboratory in Winnipeg. For confidentiality, HPV test results were blinded to the project nurse (sent in individually sealed envelopes, each identifiable by the participant’s number). This ensured that members of the research team did not have access to the names of the participants, and the project nurse, to individual test results.

Self-sampled DNA testing
DNA from self-samples was purified using Roche MagnaPure (automated, magnetic bead-based DNA extraction; Roche, Mississauga, Canada), validated specifically for HPV genotyping. Sample integrity was assayed by amplifying the housekeeping gene b-globin by PCR, as described previously.24 HPV testing was done by Hybrid Capture II (HCII), based on an antibody capturing RNA:DNA hybrids.24 HCII generically detects the 13 most common high-risk HPV types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59 and 68) at a viral load that best correlates with cervical dysplasia. For specific typing, our in-house Luminex technology,25 based on nested PCR amplification,26 was concomitantly used on all 49 participant samples. The Luminex method is less expensive than comparable commercial tests and has been successfully used previously.27

Reporting of results
Only samples that were positive for high-risk HPV were reported to the participants as “Your sample is positive with a high-risk HPV” followed by the corresponding HPV type with which they were infected. Cases testing negative for high-risk, but positive for low-risk HPV, were reported to the participants as “Your sample is negative for high-risk HPV”. When communicating HPV test results to the participating women, it was emphasised that this study was not a substitute for their biennial Pap test. Women who tested positive for a high-risk HPV type were requested to contact their family doctor or the local colposcopy clinic at the Thunder Bay Regional Health Sciences Centre. The research team provided names and contact information of the principal investigator (IZ) and the colposcopist (NE).

Statistical analyses
All analyses were carried out using PASW (formerly SPSS), version 18.0. Data obtained from the questionnaires were examined by frequency distributions and cross-tabulations. Associations between primary questions (general, self-sampling and sexual health) and secondary questions (age, education and abnormal Pap history) were assessed with the Goodman–Kruskal $\gamma$ (when both variables were ordinal) or Pearson’s $\chi^2$ test (p<0.05 was considered significant). For 2x2 tables with any expected counts <5, we used the ‘N–1’ $\chi^2$ test.28

RESULTS
The questionnaire (Appendix) was divided into three sections: general questions (including participants’ demographics—table 1), questions about self-sampling and questions about sexual health—that is, HPV and cervical cancer (table 2).

General questions
All participants reported having had previous Pap tests, with 67.3% (33/49) screened at least biennially. Fifty-one per cent (25/49) of participants reported a previous abnormal Pap test; this statistic is almost 10-fold higher than that generally seen in Ontario women.2 Participants with previous abnormal Pap tests reported that they had undergone (52%, 13/25) or were undergoing (36%, 9/25) treatment. Participants without regular Pap tests (32.7%, 16/49) reported a hiatus of up to 20 years. Regular participation in Pap screening was associated with a higher level of education (p=0.035) but not with age or previous history of abnormal Pap tests. Willingness to self-sample was not associated with previous level of participation in cervical screening. Four participants were
unsure about whether they had received HPV vaccine (Gardasil); everyone else reported that they had not.

**Self-sampling questions**

As shown in the Appendix, questions 11 and 12 each had nine ordinal response options, ranging from 1 = easy/comfortable to 9 = difficult/uncomfortable. For analysis, both questions were recorded such that 1–3 became "easy/comfortable", 4–6 "mid-range" and 7–9 "difficult/uncomfortable". For acceptability of self-sampling, 77.1% (37/48) found self-sampling easy, 6.3% (3/48) were mid-range, 16.7% (8/48) found it difficult and one did not answer (question 11). Likewise, 61.7% (29/47) participants experienced comfort with self-sampling, 23.4% (11/47) were mid-range, 14.9% (7/47) were uncomfortable and two did not answer (question 12). Thus the majority of participants found self-sampling easy and were comfortable with using it. Consequently, 87.2% (41/47) indicated willingness to participate in self-sampling screening in the future; 8.5% (4/47) did not know if they would participate more regularly; 4.2% (2/47) answered no; and two did not answer (question 13). Sixty-seven per cent (32/48) preferred self-sampling rather than an HCP taking the sample; 18.8% (9/48) had no preference, while 14.6% (7/48) preferred an HCP to take their sample (question 14). For cross-tabulations of questions 11–14 with age, educational level or a previous history of abnormal Pap tests, no statistical significance was achieved in any case.

**Sexual health questions**

**Educational methods**

We received 133 suggestions from the 49 participants about the best way to provide education about sexual health (question 15). The preferred way to learn about sexual health was through interaction with an HCP: 35% (47/133). This was followed by the use of audiovisual material—that is, watching a DVD or looking at a poster: 31.6% (42/133). Learning "on my own" and "together with my partner" were the least attractive options: 9.8% (13/133) and 7.5% (10/133), respectively.

**Cervical cancer and HPV: knowledge, attitude and behaviour**

Participants’ knowledge about cervical cancer and HPV was scored as follows, with each of two questions having five possible correct answers (questions 16 and 17; 19 and 20): 1/5 correct = some knowledge; 2/5 correct = fair knowledge; 3/5 correct = good knowledge and 4 or 5 correct = very good knowledge. Importantly, 87.8% (43/49) had knowledge ranging from "some to very good" and about half of the participants had "good or very good" knowledge about cervical cancer. For HPV biology, 69.4% (34/49) of participants had knowledge ranging from "some to very good" and about half of the participants had "good or very good" knowledge. Awareness about cervical cancer and HPV biology was not significantly associated with age, educational level or a history of abnormal Pap tests. Most participants (83.7%; 41/49) were not aware that both men and women can contract HPV infection. Information about cervical cancer and HPV was mainly obtained from an

*Only 48 participants responded to the age question. †Only 47 participants responded to the education question.
HCP—65.9% (29/44) and five participants did not answer the question or know about cervical cancer and HPV.

**Relevance and comprehension of questions**

As shown in the Appendix, questions 22 and 23 had nine ordinal response options ranging from 1=important/easy to 9—not important/difficult. For analysis, these questions were recorded such that 1–3 became ‘important/easy’, 4–6 ‘mid-range’ and 7–9 ‘not important/difficult’. Seventy-three per cent of participants (36/49) found the questions important, 6.1% (3/49) were mid-range and 20.4% (10/49) found them unimportant. Sixty-nine per cent (34/49) found the questions easy, 14.3 (7/49) were mid-range and 16.3% (8/49) found them difficult. Thus the majority of participants found the questions that they were asked to answer in the questionnaire both easy and important. The importance of the questions and ease of answering them were positively related (p<0.001). Comfort was also related to ease of answering and importance: those who felt most comfortable with self-sampling perceived the questions to be easier (p=0.000) and more important (p=0.001). However, no statistical significance was reached when both questions were cross-tabulated with age, education or abnormal Pap test history.

**HPV testing and typing**

Integrity of the self-sampled DNA was high, with 47/49 (96%) testing positive for the β-globin housekeeping gene. Overall, HPV prevalence was 28.6% (14/49); this is within the 10–30% range found in the Canadian adult population (Society of Obstetricians and Gynecologists, Ottawa, Canada).

HPV typing indicated the prevalence of all HPV types (oncogenic and non-oncogenic) in our participants. The detected high-risk HPVs (n=8) included types 16, 35, 52 and 58, which all belong to the phylogenetically related species A9 (HPV 16, 31, 33, 34, 35, 52 and 58). Interestingly, only one case was positive for HPV 39, a member of the other high-risk species, A7 (HPV 18, 26, 30, 39, 45, 51, 53, 56 and 59). Several women (n=6) were positive for low-risk types 13, 54, 83, 89 and 90, which belong to the species A9 or to other low-risk groups. Of eight positive cases with high-risk HPV examined using Luminex, only four cases were positive using the less sensitive HCII method. No association was found between testing positive for high-risk HPV and a previous history of abnormal Pap tests.

**DISCUSSION**

This initiated investigation examines HPV testing based on self-sampling in First Nation women in Ontario for the first time. Our pilot study relied on HPV-specific DNA assays of vaginal swabs provided by participants to a blinded nurse volunteer, complemented with participant feedback via a detailed questionnaire (Appendix). The participants in this pilot study were positively inclined towards self-sampling, preferring self-sampling over HCP sampling. If it becomes clear that self-sampling is an acceptable screening strategy for First Nation women in other Northwest Ontario communities, offering self sampling might be a significant alternative for the recruitment of First Nation women for cervical cancer screening. Some women (14.7%) reported discomfort with self-sampling in our pilot study, yet surprisingly there was no association between discomfort and preference for HCP sampling.

The majority of our study participants had at least some knowledge of cervical cancer and HPV. This acute awareness could be attributable to the patient demographics in our small sample size: they reported higher formal educational levels than those of average First Nation women and several participating women were local health centre employees. An unexpected finding was the low awareness that HPV can infect both men and women.

Although self-sampling was widely embraced, our participants still preferred receiving information about sexual health from an HCP and/or using audiovisual material; self-study and learning with a partner were much less popular. Indeed, most participants obtained HPV knowledge through an HCP, confirming the important role of this professional group in First Nations’ health education.

A reliable cervical cancer screening programme has to use state of the art technology. Our study used the most common, ‘best practice’ self-sampling device described in several Canadian studies—the Dacron swab. The use of vaginal tampons is not recommended because DNA extraction from tampons is time consuming and inefficient (Dr Alberto Severini, unpublished results). Two available tools can be used for cervical screening: the Pap test, with its high specificity but low sensitivity (detecting only 50% of high-grade cervical lesions), and the highly sensitive (close to 100%) HPV tests. As a primary screening tool, HPV testing can lead to increased detection of high-grade cervical lesions and allow larger screening intervals than the Pap test. Probably resulting in lower costs and higher screening participation. Furthermore, HPV testing can be conveniently performed on self-collected samples, which further reduces HCP hours and costs. Consequently, our approach included HPV testing and typing.

Self-sample integrity in our study was found to be excellent and at least similar to, or even better than, that found in other studies. The overall HPV prevalence of 28.6% (and 16.3% for high-risk types) was within the upper range of the overall Canadian population. Interestingly, typing revealed almost exclusively HPV types phylogenetically like type 16, but not type 18. Similar findings were reported recently in a study involving aboriginal women from a Northern Plain American Indian reservation outpatient clinic. Of note, our more sensitive in-house Luminex technique detected twice as many positive cases of high-risk HPV as did HCII because HCII was developed.
to detect only clinically relevant cases whereas the Luminex technique detects latent HPV infections.

Limitations
Despite the small sample size of our pilot study, similar studies among Caucasian populations in Canada and elsewhere are in agreement with our findings. Our study population differs from that which might be expected in First Nation communities, which renders generalisation difficult. The high participation in regular Pap screening may be connected to a higher level of education in our participants than among most Canadian First Nation women. Indeed, we found a positive, statistically significant association between higher education and participation in cancer screening. On the other hand, participants who did not have regular Pap screening reported intervals of up to 20 years. Self-reported rates have to be considered cautiously because of over-reporting. Indeed discrepancies between self-reporting and medical charts have been published by several independent studies with concordance rates between 65% and 89%. Our participants also had easy access to the collaborating health centre in FWFN, which advocates Pap tests for First Nation women and may explain the rather high reported rate of previous Pap tests. The situation differs for members of the other Northern Superior communities who are required to travel to larger cities like Thunder Bay for their health needs.

CONCLUSIONS AND FUTURE DIRECTIONS
Our findings indicate that HPV testing based on self-sampling is feasible among First Nation women in Ontario. The majority of women agreed that self-sampling would be the preferred way of taking the sample. We are aware, however, that the women who took part in this pilot study reported having had cytology at least once and that accessing unscreened First Nation women is challenging, a factor that will be dealt with in our larger study. A high sample quality and HPV prevalence, comparable to that of the general Canadian population, was obtained in this pilot study. Based on the success of this pilot study, we will conduct a larger-scale study of cervical cancer screening in 10 Northern Superior communities in Northwest Ontario. In view of the demographics in the communities we will be able to recruit more than 800 women. Owing to over-rated self-reporting when assessing the screening history, a chart review of previous Pap screening will be performed. A key question to be answered in the larger study will be how best to reach and provide sexual health education to underscreened women. We will also ask participating women to explicitly rate their discomfort by comparing HCP sampling with self-sampling.

### Part I: General questions

1) What is your age?
- [ ] 25-39
- [ ] 40-49
- [ ] 50-59
- [ ] No answer

2) Do you consider yourself:
- [ ] First Nation
- [ ] Métis
- [ ] Other (please specify)
- [ ] Do not know
- [ ] No answer

3) Highest level of formal schooling achieved:
- [ ] Less than High School graduate
- [ ] High School graduate
- [ ] College degree
- [ ] University degree, please specify
- [ ] Other, please specify
- [ ] No answer

4) Have you ever smoked?
- [ ] Yes
- [ ] No
- [ ] No answer

5) Is cervical cancer screening valuable?
- [ ] Yes
- [ ] No
- [ ] Do not know
- [ ] No answer

6) Have you had Gardasil vaccination?
- [ ] Yes
- [ ] No

7) Have you ever had a Pap test?
- [ ] I have Pap tests regularly (about every 2 years)
- [ ] I have had Pap tests, but not regularly
- [ ] I have never had a Pap test taken
- [ ] Do not know
- [ ] No answer

8) If you have had Pap tests before: Have you ever had an abnormal Pap test?
- [ ] Yes
- [ ] No
- [ ] Do not know
- [ ] No answer

9) If you had an abnormal Pap test before which statement best describes your present situation?
- [ ] I have been treated
- [ ] I am still being followed by my doctor
- [ ] I decided not to have treatment or further follow-up
- [ ] Do not know
- [ ] No answer

10) Have you ever used tampons?
- [ ] Yes
- [ ] No
- [ ] Do not know
- [ ] No answer
Part II: Questions about self-sampling

11) When taking your own sample today, did you find this easy or difficult? Please, answer on a scale from 1 to 9.

Easy

Difficult

1 2 3 4 5 6 7 8 9

☐ Do not know
☐ No answer

12) When taking your own sample today, did you feel comfortable or uncomfortable? Please, answer on a scale from 1 to 9.

Comfortable

Uncomfortable

1 2 3 4 5 6 7 8 9

☐ Do not know
☐ No answer

13) Assuming that self-sampling and sampling by a physician/nurse practitioner are equally good for testing what would you prefer in a future screening program?

☐ Self-sampling (at home or at Health Centre)
☐ Sample taken by a physician/nurse practitioner
☐ Does not matter
☐ Do not know
☐ No answer

14) If you have the option of using self-sampling, is it more likely that you would regularly participate in future cervical cancer screening?

☐ Yes
☐ No
☐ Do not know
☐ No answer
Part III: Questions about sexual health: HPV and cervical cancer

15) What is the best way for you to receive information about sexual health? (Check all that apply)

☐ Watching a DVD where pictures are shown and explanations are given orally at the same time
☐ Looking at a poster where things are described with pictures and text
☐ Directly interacting with a Health Care Provider to whom I can ask questions after having read a pamphlet
☐ Directly interacting with a health care provider who uses a life size model of the female reproductive tract so things can be demonstrated and we can talk about what we see
☐ On my own
☐ Together with my partner
☐ In a small group with other women I know
☐ None of the above
☐ Other suggestions:
☐ Do not know
☐ No answer

16) What do you know about cervical cancer? (Check all that apply)

☐ A form of cancer that affects middle-aged women the most
☐ A form of cancer that affects younger women the most
☐ A form of cancer that affects the lower genital tract of women
☐ Persistent infection with some types of HPV causes cervical cancer
☐ Cervical cancer is the second most common cancer in women worldwide
☐ Only women who have ever been sexually active may develop cervical cancer
☐ Both women who are and women who have ever been sexually active may develop cervical cancer
☐ Do not know
☐ No answer

17) What do you know about prevention of cervical cancer? (Check all that apply)

☐ Regular screening can almost entirely prevent me from getting it
☐ I can get a Pap test done
☐ I can get an HPV test done
☐ I would get HPV vaccine
☐ I am not in danger of getting cervical cancer if I use birth control pills
☐ I am not in danger of getting cervical cancer if my partner uses condoms during sexual activity
☐ Do not know
☐ No answer
18) Where did you obtain your knowledge about cervical cancer? (Check all that apply)

☐ By reading the information provided for this study
☐ Through a health care provider
☐ Through the newspaper/magazines
☐ Through television
☐ Through the internet
☐ Through friends/relatives
☐ Other, please specify:
☐ Do not know
☐ No answer

19) What do you know about HPV? (Check all that apply)

☐ HPV is a common sexually transmitted virus
☐ Many HPV types exist and some of them cause cervical cancer
☐ Rates of HPV infection are highest in women between the ages of 20 and 30
☐ Not all HPV infections lead to cervical cancer but all cervical cancers are most likely caused by HPV infections that do not go away
☐ If I have HPV I can get medication to treat it
☐ Both men and women can get HPV
☐ Only women can get HPV
☐ A positive HPV test is generally accompanied by pain and fever
☐ A positive HPV test is generally not accompanied by any symptoms
☐ Other, please specify:
☐ Do not know
☐ No answer

20) What do you know about prevention of HPV? (Check all that apply)

☐ Using a condom when having intercourse can decrease the likelihood of getting HPV
☐ Using a condom also helps to avoid other sexually transmitted diseases such as HIV, Chlamydia and fungus
☐ If I never have intercourse I will not get HPV
☐ By having only one or few partners I can decrease the likelihood of getting HPV
☐ By having only one or few partners I will not get HPV
☐ Using birth control pills will prevent me from getting HPV
☐ The HPV vaccine is given to girls in grade 8
☐ The HPV vaccine is given to girls and boys in grade 8
☐ Other, please specify:
☐ Do not know
☐ No answer
21) Where did you obtain your knowledge about HPV? (Check all that apply)

☐ By reading the information provided for this study
☐ Through a health care provider
☐ Through the newspaper/magazines
☐ Through television
☐ Through the internet
☐ Through friends
☐ Through relatives
☐ Through parents
☐ Other, please specify:
☐ Do not know
☐ No answer

22) What did you think about the importance of the questions we were asking you? Please, answer on a scale from 1 to 9.

😊 Important

😊 Not important

1 2 3 4 5 6 7 8 9

☐ Do not know
☐ No answer

23) Did you find that the questions were easy or difficult to answer? Please, answer on a scale from 1 to 9.

😊 Easy

😊 Difficult

1 2 3 4 5 6 7 8 9

☐ Do not know
☐ No answer

Your participation is appreciated. Thank you for your time.
