NONCOMMUTATIVE MANIFOLDS

THE INSTANTON ALGEBRA

AND ISOSPECTRAL DEFORMATIONS

Abstract

We give new examples of noncommutative manifolds that are less standard than the NC-torus or Moyal deformations of $\mathbb{R}^n$. They arise naturally from basic considerations of noncommutative differential topology and have non-trivial global features.

The new examples include the instanton algebra and the NC-4-spheres $S^4_\theta$.

We construct the noncommutative algebras $\mathcal{A} = C^\infty(S^4_\theta)$ of functions on NC-spheres as solutions to the vanishing, $\text{ch}_j(e) = 0$, $j < 2$, of the Chern character in the cyclic homology of $\mathcal{A}$ of an idempotent $e \in M_4(\mathcal{A})$, $e^2 = e$, $e = e^*$. We describe the universal noncommutative space obtained from this equation as a noncommutative Grassmanian as well as the corresponding notion of admissible morphisms. This space $\text{Gr}$ contains the suspension of a NC-3-sphere intimately related to quantum group deformations $SU_q(2)$ of $SU(2)$ but for unusual values (complex values of modulus one) of the parameter $q$ of $q$-analogues, $q = \exp(2\pi i \theta)$.

We then construct the noncommutative geometry of $S^4_\theta$ as given by a spectral triple $(\mathcal{A}, \mathcal{H}, D)$ and check all axioms of noncommutative manifolds. In a previous paper it was shown that for any Riemannian metric $g_{\mu\nu}$ on $S^4$ whose volume form $\sqrt{g} \, d^4x$ is the same as the one for the round metric, the corresponding Dirac operator gives a solution to the following quartic equation,

$$\left\langle \left( e - \frac{1}{2} \right) [D, e]^4 \right\rangle = \gamma_5$$

where $\langle \rangle$ is the projection on the commutant of $4 \times 4$ matrices.

We shall show how to construct the Dirac operator $D$ on the noncommutative 4-spheres $S^4_\theta$ so that the previous equation continues to hold without any change.

Finally, we show that any compact Riemannian spin manifold whose isometry group has rank $r \geq 2$ admits isospectral deformations to noncommutative geometries.
I Introduction

It is important to have available examples of noncommutative manifolds that are less standard than the NC-torus \( \mathbb{T} \) or the old Moyal deformation of \( \mathbb{R}^n \) whose algebra is boring. This is particularly so in view of the upsurge of activity in the interaction between string theory and noncommutative geometry started in \([11],[22],[25]\).

The new examples should arise naturally, have non-trivial global features (and also pass the test of noncommutative manifolds as defined in \([8]\)).

This paper will provide and analyse very natural such new examples, including the instanton algebra and the NC-4-spheres \( S^4_\theta \), obtained from basic considerations of noncommutative differential topology.

We shall also show quite generally that any compact Riemannian spin manifold whose isometry group has rank \( r \geq 2 \) admits isospectral deformations to noncommutative geometries.

A noncommutative geometry is described by a spectral triple

\[
(\mathcal{A}, \mathcal{H}, D) \tag{1}
\]

where \( \mathcal{A} \) is a noncommutative algebra with involution \( * \), acting in the Hilbert space \( \mathcal{H} \) while \( D \) is a self-adjoint operator with compact resolvent and such that,

\[
[D, a] \text{ is bounded } \forall a \in \mathcal{A}. \tag{2}
\]

The operator \( D \) plays in general the role of the Dirac operator \([19]\) in ordinary Riemannian geometry. It specifies both the metric on the state space of \( \mathcal{A} \) by

\[
d(\varphi, \psi) = \text{Sup } \{|\varphi(a) - \psi(a)|; \|D, a\| \leq 1\} \tag{3}
\]

and the \( K \)-homology fundamental class (cf. \([8]\)). What holds things together in this spectral point of view on NCG is the nontriviality of the pairing between the \( K \)-theory of the algebra \( \mathcal{A} \) and the \( K \)-homology class of \( D \), given in the even case by

\[
[e] \in K_0(\mathcal{A}) \rightarrow \text{Index } D^+_e \in \mathbb{Z}. \tag{4}
\]

Here \([e]\) is the class of an idempotent

\[
e \in M_r(\mathcal{A}), \ e^2 = e, \ e = e^* \tag{5}
\]

in the algebra of \( r \times r \) matrices over \( \mathcal{A} \), and

\[
D^+_e = e D^+ e, \tag{6}
\]

where \( D^+ = D(\frac{1+\gamma}{2}) \) is the restriction of \( D \) to the range \( \mathcal{H}^+ \) of \( \frac{1+\gamma}{2} \) and \( \gamma \) is the \( \mathbb{Z}/2 \) grading of \( \mathcal{H} \) in the even case; thus \( D \) is of the form,

\[
D = \begin{bmatrix} 0 & D^* \\ D^+ & 0 \end{bmatrix}, \quad \gamma = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \tag{7}
\]

The corner stone of the general theory is an operator theoretic index formula \([8],[12],[16]\) which expresses the above index pairing \([4]\) by explicit local cyclic cocycles on the algebra \( \mathcal{A} \). These local formulas become extremely simple in the special case where only the top component of the Chern character \( \text{Ch}(e) \) in cyclic homology fails to vanish.
This is easy to understand in the analogous simpler case of ordinary manifolds since the Atiyah-Singer index formula gives the integral of the product of the Chern character $\text{Ch}(E)$, of the bundle $E$ over the manifold $M$, by the index class; if the only component of $\text{Ch}(E)$ is $\text{ch}_n$, $n = \frac{1}{2} \dim M$ only the 0-dimensional component of the index class is involved in the index formula.) Under this assumption the index formula reduces indeed to the following,

$$\text{Index } D_e^+ = (-1)^m \int \gamma \left( e - \frac{1}{2} \right) [D,e]^{2m} D^{-2m}$$  \hspace{1cm} (8)

provided the components $\text{ch}_j(e)$ all vanish for $j < m$. Here $\gamma$ is the $\mathbb{Z}/2$ grading of $\mathcal{H}$ as above, the resolvent of $D$ is of order $\frac{1}{2m}$ (i.e. its characteristic values $\mu_k$ are $0(k^{-\frac{1}{2m}})$) and $f$ is the coefficient of the logarithmic divergency in the ordinary operator trace $\int$. We began in [10] to investigate the algebraic relations implied by the vanishing,

$$\text{ch}_j(e) = 0 \quad j < m,$$  \hspace{1cm} (9)

of the Chern character of $e$ in the cyclic homology of $\mathcal{A}$. Note that this vanishing at the chain level is a much stronger condition than the vanishing of the usual Chern differential form.

For $m = 1$ (and $r = 2$ in [10]) we found commutative solutions with $\mathcal{A} = C^\infty(S^2)$ as the algebra generated by the matrix components,

$$e_{ij}, \quad e = [e_{ij}] \in M_2(\mathcal{A}).$$  \hspace{1cm} (10)

In fact, for $m = 1$ the commutativity is imposed by the relations $e^2 = e, e = e^*$ and $\text{ch}_0(e) = 0$.

For $m = 2$ (and $r = 4$ in [10]) we also found commutative solutions with $\mathcal{A} = C^\infty(S^4)$ where $S^4$ appears as quaternionic projective space but the computations of [10] used an “Ansatz” and did not analyse the general solution. In particular this left open the possibility of a noncommutative solution for $m = 2$ (and $r = 4$). We shall show in this paper that such noncommutative solutions do exist and provide very natural examples of NC 4-spheres $S^4_\theta$. We shall also describe the noncommutative space associated to (9) for $m = 2$ (and $r = 4$) as a noncommutative Grassmanian as well as the corresponding notion of admissible morphisms. This space $\text{Gr}$ contains the suspension of a NC-3-sphere which is intimately related to quantum group deformations of $SU(2)$ but for complex values of modulus one of the usual parameter $q$ of $q$-analogues, $q = \exp(2\pi i \theta)$. Our next task will be to analyse the metrics (i.e. the operators $D$) on our solutions of equation (9).

In [10] it was shown that for any Riemannian metric $g_{\mu\nu}$ on $S^4$ whose volume form $\sqrt{g}d^4x$ is the same as the one for the round metric, the corresponding Dirac operator gives a solution to the following quartic equation,

$$\left\langle \left( e - \frac{1}{2} \right) [D,e]^4 \right\rangle = \gamma_5$$  \hspace{1cm} (11)

where $\langle \cdots \rangle$ is the projection on the commutant of $4 \times 4$ matrices (recall that $e \in M_4(\mathcal{A})$ is a $4 \times 4$ matrix).
We shall show in this paper how to construct the Dirac operator on the noncommutative 4-spheres $S^4_\theta$ so that equation (11) continues to hold without any change. Combining this equation (11) with the index formula gives a quantization of the volume,

$$\int ds^4 \in \mathbb{N} \quad ds = D^{-1}$$

(12)

and fixes (in a given $K$-homology class for the operator $D$) the leading term of the spectral action [3],

$$\text{Trace} \left( f \left( \frac{D}{\Lambda} \right) \right) = \frac{\Lambda^4}{2} \int ds^4 + \cdots$$

(13)

Since the next term is the Hilbert-Einstein action in the usual Riemannian case [3], [18], [17], it is very natural to compare various solutions (commutative or not) of (11) using this action.

II Components of the Chern character and the Instanton algebra

Let $\mathcal{A}$ be an algebra (over $\mathbb{C}$) and

$$e \in M_r(\mathcal{A}), \quad e^2 = e$$

(1)

be an idempotent.

The component $\text{ch}_n(e)$ of the (reduced) Chern character of $e$ is an element of

$$\mathcal{A} \otimes \overline{\mathcal{A}} \otimes \cdots \otimes \overline{\mathcal{A}}$$

(2)

where $\overline{\mathcal{A}} = \mathcal{A}/\mathbb{C}1$ is the quotient of $\mathcal{A}$ by the scalar multiples of the unit 1. The formula for $\text{ch}_n(e)$ is (with $\lambda_n$ a normalization constant),

$$\text{ch}_n(e) = \lambda_n \sum \left( e_{i_0i_1} - \frac{1}{2} \delta_{i_0i_1} \right) \otimes e_{i_1i_2} \otimes e_{i_2i_3} \cdots \otimes e_{i_{2n-1}i_0}$$

(3)

where $\delta_{ij}$ is the usual Kronecker symbol and only the class $\overline{e}_{i_0i_{k+1}} \in \overline{\mathcal{A}}$ is used in the formula. The crucial property of the components $\text{ch}_n(e)$ is that they define a cycle in the $(b,B)$ bicomplex of cyclic homology [5], [20],

$$B \text{ch}_n(e) = b \text{ch}_{n+1}(e).$$

(4)

For any pair of integers $m, r$ we let $\mathcal{A}_{m,r}$ be the universal algebra associated to the relations,

$$\text{ch}_j(e) = 0 \quad \forall j < m.$$ (5)

More precisely we let $\mathcal{A}_{m,r}$ be generated by the $r^2$ elements $e_{ij}; i,j \in \{1, \ldots, r\}$ and we first impose the relations

$$e^2 = e \quad e = [e_{ij}].$$ (6)

An admissible homomorphism,

$$\rho : \mathcal{A}_{m,r} \rightarrow \mathcal{B},$$

(7)
to an arbitrary algebra $\mathcal{B}$, is given by the $\rho(e_{ij}) \in \mathcal{B}$ which fulfill

$$\rho(e)^2 = \rho(e),$$

and $\text{ch}_j(\rho(e)) = 0$ for $j < m$, thus

$$\sum \left( \rho(e_{i_0i_1}) - \frac{1}{2} \delta_{i_0i_1} \right) \otimes \rho(e_{i_1i_2}) \otimes \cdots \otimes \rho(e_{i_{2j}i_0}) = 0$$

where the symbol $\sim$ means that only the class in $\mathcal{B}$ matters. We define $\mathcal{A}_{m,r}$ as the quotient of the algebra defined by (6) by the intersection of kernels of all admissible morphisms $\rho$.

Elements of the algebra $\mathcal{A}_{m,r}$ can be represented as polynomials in the generators $e_{ij}$ and to prove that such a polynomial $P(e_{ij})$ is non zero in $\mathcal{A}_{m,r}$ one must construct a solution to the above equations for which $P(e_{ij}) \neq 0$.

To get a $C^*$ algebra we endow $\mathcal{A}_{m,r}$ with the involution given by,

$$(e_{ij})^* = e_{ji}$$

which means that $e = e^*$ in $M_r(\mathcal{A})$. We define a norm by,

$$\|P\| = \text{Sup} \|\pi(P)\|$$

where $\pi$ ranges through all representations of the above equations in Hilbert space. Such a $\pi$ is given by a Hilbert space $\mathcal{H}$ and a self-adjoint idempotent,

$$E \in M_r(\mathcal{L}(\mathcal{H})), \quad E^2 = E, \quad E = E^*$$

such that (9) holds for $\mathcal{B} = \mathcal{L}(\mathcal{H})$.

One checks that for any polynomial $P(e_{ij})$ the quantity (11), i.e. the supremum of the norms,

$$\|P(E_{ij})\|$$

is finite.

We let $A_{m,r}$ be the $C^*$ algebra obtained as the completion of $\mathcal{A}_{m,r}$ for the above norm.

To get familiar with the (a priori noncommutative) spaces $\text{Gr}_{m,r}$ such that,

$$A_{m,r} = C(\text{Gr}_{m,r})$$

we shall first recall from [10] what happens in the simplest case $m = 1$, $r = 2$.

One has $e = \begin{bmatrix} e_{11} & e_{12} \\ e_{21} & e_{22} \end{bmatrix}$ and the condition (7) just means that

$$e_{11} + e_{22} = 1$$

while (8) means that

$$e_{11}^2 + e_{12} e_{21} = e_{11}, \quad e_{11} e_{12} + e_{12} e_{22} = e_{12},$$

$$e_{21} e_{11} + e_{22} e_{21} = e_{21}, \quad e_{21} e_{12} + e_{22}^2 = e_{22}.$$

By (11) we get $e_{11} - e_{11}^2 = e_{22} - e_{22}^2$, so that (16) shows that $e_{12} e_{21} = e_{21} e_{12}$. We also see that $e_{12}$ and $e_{21}$ both commute with $e_{11}$. This shows that $A_{1,2}$ is commutative and
allows to check that $Gr_{1,2} = S^2$ is the 2-sphere. Thus $Gr_{1,2}$ is an ordinary commutative space.

Next, we move on to the case $m = 2$, $r = 4$. Our main task now will be to show that $Gr_{2,4}$ is a very interesting noncommutative space. Note that the notion of admissible morphism is a non trivial piece of structure on $Gr_{2,4}$ since the identity map is not admissible.

We can first reformulate the construction of [10] section XI and get an admissible surjection,

$$A_{2,4} \xrightarrow{\sigma} C(S^4) \quad (17)$$

where $S^4$ appears naturally as quaternionic projective space, $S^4 = P_1(\mathbb{H})$.

Let us recall from [10] that the equality,

$$E(x) = \begin{bmatrix} t & q \\ \overline{q} & 1 - t \end{bmatrix} \in M_4(\mathbb{C}) \quad (18)$$

for $x = (q, t)$ given by a pair of a quaternion $q = \left[ \begin{array}{cc} \alpha & \beta \\ -\beta^* & \alpha^* \end{array} \right]$ and a real number $t$ such that

$$q\overline{q} = t - t^2 \quad (19)$$

defines a map from the 4-sphere $S^4$ (the double of the 4-disk $\|q\| \leq 1$) to the Grassmanian of 2-dimensional projections $E = E^2 = E^*$ in $M_4(\mathbb{C})$ such that,

$$\text{Trace} \left( F(x) F(y) F(z) \right) = 0 \quad \forall \ x, y, z \in S^4 \quad (20)$$

where $F(x) = 2E(x) - 1$ is the corresponding self-adjoint isometry.

The equality XI.54 of [10] is weaker than this statement but examining the proof one gets (20). To formulate the result for arbitrary even spheres $S^{2m}$ we note first that using (4) the equality

$$\omega = \text{ch}_m(e) \quad (21)$$

defines a Hochschild cycle $\rho(\omega) \in Z_{2m}(\mathcal{B})$ for any admissible morphism $\rho : A_{m,r} \rightarrow \mathcal{B}$. We let $r = 2^m$ and construct an admissible surjection,

$$A_{m,2^m} \xrightarrow{\sigma} C(S^{2m}) \quad (22)$$

which is non trivial inasmuch as

$$\sigma(\omega) = v \quad (23)$$

is the volume form of the round oriented sphere.

To construct $\sigma$ we let $C = \text{Cliff}(\mathbb{R}^{2m})$ be the Clifford algebra of the (oriented) Euclidean space $\mathbb{R}^{2m}$. We identify $S^{2m}$ with the space of pairs $(\xi, t)$, $\xi \in \mathbb{R}^{2m}$ and $t \in [-1, 1]$ such that $\|\xi\|^2 + t^2 = 1$. We then define a map from $S^{2m}$ to the Grassmanian of self-adjoint idempotents in $C$ by

$$E(\xi, t) = \frac{1}{2} + \frac{1}{2} (\gamma(\xi) + t \gamma) \quad (24)$$

where $\gamma(\xi)$ is the usual inclusion of $\mathbb{R}^{2m}$ in $C$ such that

$$\gamma(\xi)^2 = \|\xi\|^2, \ \gamma(\xi) = \gamma(\xi)^* \quad (25)$$
and $\gamma \in C$, $\gamma^* = \gamma$, $\gamma^2 = 1$ is the $\mathbb{Z}/2$ grading associated with the chosen orientation of $\mathbb{R}^{2m}$. One has $\gamma \gamma(\xi) = -\gamma(\xi) \gamma$ for any $\xi$ which allows to check that $\gamma(\xi) + t \gamma$ is an involution and $E$ a self-adjoint idempotent. Next, for $\ell < 2m$, $\ell$ odd,

$$\text{Trace} ((\gamma(\xi_1) + t_1 \gamma) \ldots (\gamma(\xi_\ell) + t_\ell \gamma)) = 0 \quad \forall \xi_j, t_j.$$  \hspace{1cm} (26)

Indeed the coefficient of monomials in $t$ of even degree is of the form $\text{Trace} (\gamma(\xi_1) \ldots \gamma(\xi_{2k+1}))$ which vanishes by anticommutation with $\gamma$. The coefficient of monomials in $t$ of odd degree is of the form $\text{Trace} (\gamma(\xi_1) \ldots \gamma(\xi_{2k}) \gamma)$ where $k < m$. It vanishes because $\gamma$ is orthogonal to all the lower filtration of $C$. We thus get,

$$\text{Trace} \left( \left( E(x_1) - \frac{1}{2} \right) \ldots \left( E(x_\ell) - \frac{1}{2} \right) \right) = 0 \quad \forall x_1, \ldots, x_\ell \in S^{2m} \hspace{1cm} (27)$$

provided $\ell$ is odd, $\ell < 2m$. Hence $E$ defines an admissible homomorphism $\sigma : A_{m,2m} \to C(S^{2m})$ and one has, as in [10], the following result,

**Theorem 1**  

a) $E \in C^\infty(S^{2m}, M_r(\mathbb{C}))$ satisfies $E = E^2 = E^*$ and $\text{ch}_j(E) = 0 \quad \forall j < m$.

b) The Hochschild cycle $\omega = \text{ch}_m(E)$ is the volume form of the round sphere $S^{2m}$.

c) Let $g$ be a Riemannian metric on $S^{2m}$ with volume form $\sqrt{g} d^{2m}x = \omega$, then the corresponding Dirac operator $D$ fulfills

$$\left\langle \left( e - \frac{1}{2} \right) [D, e]^{2m} \right\rangle = \gamma$$

where $e = E$ as above and $\langle \rangle$ is the projection on the commutant of $M_r(\mathbb{C})$.

We have identified $M_r(\mathbb{C})$ with the Clifford algebra $C$, $r = 2^m$. This result shows in particular that $\text{Gr}_{m,r}, r = 2^m$, contains $S^{2m}$ in such a way that $\omega|S^{2m}$ is the volume form for the round metric. The proof is the same as in [10].

**III The noncommutative 4-sphere**

Let us now move on to the inclusion $S^4_\theta \subset \text{Gr}_{2,4}$ where $S^4_\theta$ is the noncommutative 4-sphere we are about to describe.

One should observe from the outset that the compact Lie group $SU(4)$ acts by automorphisms,

$$SU(4) \subset \text{Aut} (C^\infty \text{Gr}_{2,4})$$  \hspace{1cm} (1)

by the following operation,

$$e \rightarrow U e U^*$$  \hspace{1cm} (2)

where $U \in SU(4)$ is viewed as a $4 \times 4$ matrix and $e = [e_{ij}]$ as above.
We shall now show that the algebra $C(\text{Gr}_{2,4})$ is noncommutative by constructing explicit admissible surjections,

$$C(\text{Gr}_{2,4}) \to C(S^4_{\theta})$$

(3)

whose form is dictated by natural deformations of the 4-sphere similar in spirit to the standard deformation of $T^2$ to $T^2_{\theta}$.

We first determine the algebra generated by $M_4(C)$ and a projection $e = e^*$ such that $\langle e - \frac{1}{2} \rangle = 0$ as above and whose two by two matrix expression is of the form,

$$[e^{ij}] = \begin{bmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{bmatrix}$$

(4)

where each $q_{ij}$ is a $2 \times 2$ matrix of the form,

$$q = \begin{bmatrix} \alpha & \beta \\ -\lambda \beta^* & \alpha^* \end{bmatrix},$$

(5)

and $\lambda = \exp(2\pi i \theta)$ is a complex number of modulus one, different from -1 for convenience. Since $e = e^*$, both $q_{11}$ and $q_{22}$ are selfadjoint, moreover since $\langle e - \frac{1}{2} \rangle = 0$, we can find $t = t^*$ such that,

$$q_{11} = \begin{bmatrix} t & 0 \\ 0 & t \end{bmatrix}, \quad q_{22} = \begin{bmatrix} (1-t) & 0 \\ 0 & (1-t) \end{bmatrix}.$$  

(6)

We let $q_{12} = \begin{bmatrix} \alpha & \beta \\ -\lambda \beta^* & \alpha^* \end{bmatrix}$, we then get from $e = e^*$,

$$q_{21} = \begin{bmatrix} \alpha^* & -\bar{\lambda} \beta \\ \beta^* & \alpha \end{bmatrix}.$$  

(7)

We thus see that the commutant $B_{\theta}$ of $M_4(C)$ is generated by $t, \alpha, \beta$ and we first need to find the relations imposed by the equality $e^2 = e$.

In terms of

$$e = \begin{bmatrix} t & q \\ q^* & 1-t \end{bmatrix},$$

(8)

the equation $e^2 = e$ means that $t^2 - t + qq^* = 0$, $t^2 - t + q^*q = 0$ and $[t, q] = 0$. This shows that $t$ commutes with $\alpha$, $\beta$, $\alpha^*$ and $\beta^*$ and since $qq^* = q^*q$ is a diagonal matrix

$$\alpha^* \alpha = \alpha^* \alpha, \quad \alpha \beta = \lambda \beta \alpha, \quad \alpha^* \beta = \bar{\lambda} \alpha \beta^*, \quad \beta \beta^* = \beta^* \beta$$

(9)

so that the $C^*$ algebra $B_{\theta}$ is not commutative for $\lambda$ different from 1. The only further relation is, (besides $t = t^*$),

$$\alpha \alpha^* + \beta \beta^* + t^2 - t = 0.$$  

(10)

We denote by $S^4_{\theta}$ the corresponding noncommutative space, so that $C(S^4_{\theta}) = B_{\theta}$. It is by construction the suspension of the noncommutative 3-sphere $S^3_{\theta}$ whose coordinate algebra is generated by $\alpha$ and $\beta$ as above and say the special value $t = 1/2$. This noncommutative 3-sphere is related by analytic continuation of the parameter to the quantum group $SU(2)_q$, but the usual theory requires $q$ to be real whereas we need a complex number of modulus one which spoils the unitarity of the coproduct $[27]$. Had we taken the deformation parameter to be real, $\lambda = q \in \mathbb{R}$, like in $[14]$ we would
have obtained a different deformation $S^4_q$ of the commutative sphere $S^4$, whose algebra is different from the above one. More important, the two dimensional component $ch_1(e)$ of the Chern character would not vanish.

We shall now check that for the sphere $S^4_\theta$ the two dimensional component $ch_1(e)$ automatically vanishes as an element of the (normalized) ($b,B$)-bicomplex so that,

$$ch_n(e) = 0, \ n = 0, 1.$$  \hspace{1cm} (11)

With $q = \left[ \begin{array}{cc} \alpha & \beta \\ -\lambda^* & \alpha^* \end{array} \right]$, we get,

$$ch_1(e) = \left\langle \left( t - \frac{1}{2} \right) (dq dq^* - dq^* dq) + q (dq^* dt - dt dq^*) + q^* (dt dq - dq dt) \right\rangle$$  \hspace{1cm} (12)

where the expectation in the right hand side is relative to $M_2(\mathbb{C})$ and we use the notation $d$ instead of the tensor notation.

The diagonal elements of $\omega = dq dq^*$ are

$$\omega_{11} = d\alpha d\alpha^* + d\beta d\beta^*, \ \omega_{22} = d\beta^* d\beta + d\alpha^* d\alpha$$

while for $\omega' = dq^* dq$ we get,

$$\omega'_{11} = d\alpha^* d\alpha + d\beta d\beta^*, \ \omega'_{22} = d\beta^* d\beta + d\alpha d\alpha^*.$$

It follows that, since $t$ is diagonal,

$$\left\langle \left( t - \frac{1}{2} \right) (dq dq^* - dq^* dq) \right\rangle = 0.$$  \hspace{1cm} (13)

The diagonal elements of $q dq^* dt = \rho$ are

$$\rho_{11} = \alpha d\alpha^* dt + \beta d\beta^* dt, \ \rho_{22} = \beta^* d\beta dt + \alpha^* d\alpha dt$$

while for $\rho' = q^* dq dt$ they are

$$\rho'_{11} = \alpha^* d\alpha dt + \beta d\beta^* dt, \ \rho'_{22} = \beta^* d\beta dt + \alpha d\alpha^* dt.$$

Similarly for $\sigma = q dt dq^*$ and $\sigma' = q^* dt dq$ one gets the required cancellations so that,

$$ch_1(e) = 0.$$  \hspace{1cm} (14)

We thus get,

**Theorem 2**  \hspace{1cm} a) $e \in C^\infty(S^4_\theta, M_4(\mathbb{C}))$ satisfies $e = e^2 = e^*$ and $ch_j(e) = 0 \ \forall \ j < 2.$

b) $Gr_{2,4}$ is a noncommutative space and $S^4_\theta \subset Gr_{2,4}.$
Since \( ch_1(e) = 0 \), it follows that \( ch_2(e) \) is a Hochschild cycle which will play the role of the round volume form on \( S^4_\theta \) and that we shall now compute. With the above notations one has,

\[
ch_2(e) = \left\langle t - \frac{1}{2}, \frac{q}{2} - t \right\rangle \left( \frac{dt}{dq^*} - \frac{dq}{dt} \right)^4
\]

and the sum of the diagonal elements is

\[
\left(t - \frac{1}{2}\right) \left( (dt^2 + dq dq^*)^2 + (dt dq - dq dt)(dq^* dt - dt dq^*) \right)
- \left(t - \frac{1}{2}\right) \left( (dq^* dt - dt dq^*)(dt dq - dq dt) + (dq^* dq + dt^2)^2 \right)
+ q \left( (dq^* dt - dt dq^*)(dt^2 + dq dq^*) + (dq^* dq + dt^2)(dq^* dt - dt dq^*) \right)
+ q^* \left( (dt^2 + dq dq^*)(dt dq - dq dt) + (dt dq - dq dt)(dq^* dq + dt^2) \right).
\]

Since \( t \) and \( dt \) are diagonal \( 2 \times 2 \) matrices of operators and the same diagonal terms appear in \( dq dq^* \) and \( dq^* dq \), by the same argument by which we got the vanishing (13), the first two lines only contribute by,

\[
\left\langle \left(t - \frac{1}{2}\right) (dq dq^* dq dq^* - dq^* dq dq^* dq) \right\rangle.
\]

Similarly, the last two lines only contribute by

\[
\left\langle q^* (dt dq dq^* dq - dq dt dq^* dq + dq dq^* dt dq - dq dq^* dq dt) \right\rangle
- q \left( dt dq dq^* dq dq^* - dq^* dt dq^* dq + dq^* dq dt dq^* - dq^* dq dq^* dt \right)\).
\]

The direct computation gives \( ch_2(e) \) as a sum of five components

\[
ch_2(e) = \left( t - \frac{1}{2} \right) \Gamma_t + \alpha \Gamma_\alpha + \alpha^* \Gamma_{\alpha^*} + \beta \Gamma_\beta + \beta^* \Gamma_{\beta^*},
\]

with the operators \( \Gamma_t, \Gamma_\alpha, \Gamma_{\alpha^*}, \Gamma_\beta, \Gamma_{\beta^*} \) explicitly given by

\[
\Gamma_t = \left( d\alpha d\alpha^* - d\alpha^* d\alpha \right)(d\beta d\beta^* - d\beta^* d\beta) + (d\beta d\beta^* - d\beta^* d\beta)(d\alpha d\alpha^* - d\alpha^* d\alpha)
+ (d\alpha d\beta - \lambda d\beta d\alpha)(d\beta^* d\alpha^* - \bar{\lambda} d\alpha^* d\beta^*)
+ (d\beta^* d\alpha - \bar{\lambda} d\alpha^* d\beta)(d\alpha d\beta^* - \lambda d\beta^* d\alpha)
+ (d\alpha^* d\beta - \lambda d\beta d\alpha^*)(d\alpha^* d\beta^* - \bar{\lambda} d\beta^* d\alpha^*)
;\]

\[
\Gamma_\alpha = \left( dt d\alpha^* - d\alpha^* dt \right)(d\beta^* d\beta - d\beta d\beta^*)
+ (d\beta^* d\beta - d\beta d\beta^*)(dt d\alpha^* - d\alpha^* dt)
+ (d\beta^* dt - dt d\beta)(d\alpha^* d\alpha^* - \lambda d\alpha^* d\beta^*)
+ \lambda (d\beta^* d\alpha^* - \bar{\lambda} d\alpha^* d\beta^*)(d\beta dt - dt d\beta)
+ (d\alpha^* d\beta - \lambda d\beta d\alpha^*)(d\beta^* dt - dt d\beta^*)
+ \lambda (d\beta^* dt - dt d\beta^*)(d\alpha^* d\beta - \lambda d\beta d\alpha^*)
;\]
\[ \Gamma_{\alpha^*} = (dt \, d\alpha - d\alpha \, dt)(d\beta \, d\beta^* - d\beta^* \, d\beta) \]
\[ + (d\beta \, d\beta^* - d\beta^* \, d\beta)(dt \, d\alpha - d\alpha \, dt) \]
\[ + (d\alpha \, d\beta - \lambda \, d\beta \, d\alpha)(dt \, d\beta^* - d\beta^* \, dt) \]
\[ + \bar{\lambda} (dt \, d\beta^* - d\beta^* \, dt)(d\alpha \, d\beta - \lambda \, d\beta \, d\alpha) \]
\[ + (dt \, d\beta - d\beta \, dt)(d\beta^* \, d\alpha - \lambda \, d\alpha \, d\beta^*) \]
\[ + \bar{\lambda} (d\beta^* \, d\alpha - \lambda \, d\alpha \, d\beta^*)(dt \, d\beta - d\beta \, dt); \]

\[ \Gamma_{\beta} = (dt \, d\beta^* - d\beta^* \, dt)(d\alpha \, d\alpha - d\alpha \, d\alpha^*) \]
\[ + (d\alpha^* \, d\alpha - d\alpha \, d\alpha^*)(dt \, d\beta^* - d\beta^* \, dt) \]
\[ + \lambda (dt \, d\alpha - d\alpha \, dt)(d\beta^* \, d\alpha^* - \bar{\lambda} \, d\alpha^* \, d\beta^*) \]
\[ + (d\beta^* \, d\alpha^* - \bar{\lambda} \, d\alpha^* \, d\beta^*)(dt \, d\alpha - d\alpha \, dt) \]
\[ + \bar{\lambda} (d\alpha^* \, dt - dt \, d\alpha^*)(d\beta^* \, d\alpha - \lambda \, d\alpha \, d\beta^*) \]
\[ + (d\beta^* \, d\alpha - \lambda \, d\alpha \, d\beta^*)(d\alpha^* \, dt - dt \, d\alpha^*); \]

\[ \Gamma_{\beta^*} = (dt \, d\beta - d\beta \, dt)(d\alpha^* \, d\alpha - d\alpha \, d\alpha^*) \]
\[ + (d\alpha \, d\alpha^* - d\alpha^* \, d\alpha)(dt \, d\beta - d\beta \, dt) \]
\[ + (d\alpha^* \, dt - dt \, d\alpha^*)(d\alpha \, d\beta - \lambda \, d\beta \, d\alpha) \]
\[ + \bar{\lambda} (d\alpha \, d\beta - \lambda \, d\beta \, d\alpha)(d\alpha^* \, dt - dt \, d\alpha^*) \]
\[ + (dt \, d\alpha - d\alpha \, dt)(d\alpha^* \, d\beta - \bar{\lambda} \, d\beta \, d\alpha^*) \]
\[ + \lambda (d\alpha^* \, d\beta - \bar{\lambda} \, d\beta \, d\alpha^*)(dt \, d\alpha - d\alpha \, dt). \]

One can equivalently (in order to avoid any confusion with ordinary differentials) write the Hochschild cycle \( c = ch_2(e) \) as

\[ c = (t - \frac{1}{2}) \, c_t + \alpha \, c_\alpha + \alpha^* \, c_{\alpha^*} + \beta \, c_\beta + \beta^* \, c_{\beta^*}; \]

where the components \( c_t, c_\alpha, c_{\alpha^*}, c_\beta, c_{\beta^*} \), which are elements in \( B_\theta \otimes B_\theta \otimes B_\theta \otimes B_\theta \), have an expression of the same form as the corresponding operators in (20-24) with the symbol \( d \) substituted by the tensor product symbol \( \otimes \). The vanishing of \( bc \), which has six hundred terms, can be checked directly from the commutation relations (9). The cycle \( c \) is totally ‘\( \lambda \)-antisymmetric’.

**IV  The noncommutative geometry of \( S_\theta^4 \)**

The next step consists in finding the Dirac operator which gives a solution to the basic quartic equation (I.11). Let \( \mathcal{A} = C^\infty(S_\theta^4) \) be the algebra of smooth functions on the noncommutative sphere \( S_\theta^4 \). We shall now describe a spectral triple

\[ (\mathcal{A}, \mathcal{H}, D) \]
which describes the geometry on $S^4_{\theta}$ corresponding to the round metric.
In order to do that we first need to find good coordinates on $S^4_{\theta}$ in terms of which the operator $D$ will be easily expressed. We choose to parametrize $\alpha, \beta$ and $t$ as follows,
\[
\alpha = \frac{u}{2} \cos \varphi \cos \psi, \quad \beta = \frac{v}{2} \sin \varphi \cos \psi, \quad t = \frac{1}{2} + \frac{1}{2} \sin \psi. \tag{2}
\]
Here $\varphi$ and $\psi$ are ordinary angles with domain
\[
0 \leq \varphi \leq \frac{\pi}{2}, \quad -\frac{\pi}{2} \leq \psi \leq \frac{\pi}{2}, \tag{3}
\]
while $u$ and $v$ are the usual unitary generators of the algebra $C^\infty(\mathbb{T}_2^2)$ of smooth functions on the noncommutative 2-torus. Thus the presentation of their relations is
\[
uv = \lambda vu, \quad uu^* = u^*u = 1, \quad vv^* = v^*v = 1. \tag{4}
\]
One checks that $\alpha, \beta, t$ given by (2) satisfy the basic presentation of the generators of $C^\infty(S^4_{\theta})$ which thus appears as a subalgebra of the algebra generated (and then closed under smooth calculus) by $e^{i\varphi}, e^{i\psi}, u$ and $v$.
For $\theta = 0$ one readily computes the round metric,
\[
G = 4 (d\alpha d\overline{\alpha} + d\beta d\overline{\beta} + dt^2) \tag{5}
\]
and in terms of the coordinates, $\varphi, \psi, u, v$ one gets,
\[
G = \cos^2 \varphi \cos^2 \psi du d\overline{u} + \sin^2 \varphi \cos^2 \psi dv d\overline{v} + \cos^2 \psi d\varphi^2 + d\psi^2. \tag{6}
\]
Up to normalization, its volume form is given by
\[
\sin \varphi \cos \varphi (\cos \psi)^3 \overline{u} du \wedge \overline{v} dv \wedge d\psi \wedge d\varphi \tag{7}
\]
In terms of these rectangular coordinates we get the following simple expression for the Dirac operator,
\[
D = (\cos \varphi \cos \psi)^{-1} u \frac{\partial}{\partial u} \gamma_1 + (\sin \varphi \cos \psi)^{-1} v \frac{\partial}{\partial v} \gamma_2 + \frac{1}{\cos \psi} \sqrt{-1} \left( \frac{\partial}{\partial \varphi} + \frac{1}{2} \cot \varphi - \frac{1}{2} \tan \varphi \right) \gamma_3 + \sqrt{-1} \left( \frac{\partial}{\partial \psi} - \frac{3}{2} \tan \psi \right) \gamma_4. \tag{8}
\]
Here $\gamma_\mu$ are the usual Dirac $4 \times 4$ matrices with
\[
\{\gamma_\mu, \gamma_\nu\} = 2 \delta_\mu^\nu, \quad \gamma_\mu^* = \gamma_\mu. \tag{9}
\]
It is now easy to move on to the noncommutative case, the only tricky point is that there are nontrivial boundary conditions for the operator $D$, but we shall just leave them unchanged in the NC case, the only thing which changes is the algebra and the way it acts in the Hilbert space. The formula for the operator $D$ is now,
\[
D = (\cos \varphi \cos \psi)^{-1} \delta_1 \gamma_1 + (\sin \varphi \cos \psi)^{-1} \delta_2 \gamma_2 + \frac{1}{\cos \psi} \sqrt{-1} \left( \frac{\partial}{\partial \varphi} + \frac{1}{2} \cot \varphi - \frac{1}{2} \tan \varphi \right) \gamma_3 + \sqrt{-1} \left( \frac{\partial}{\partial \psi} - \frac{3}{2} \tan \psi \right) \gamma_4. \tag{10}
\]
where the $\gamma_\mu$ are the usual Dirac matrices and where $\delta_1$ and $\delta_2$ are the standard derivations of the NC torus so that

$$\begin{align*}
\delta_1(u) &= u, \quad \delta_1(v) = 0, \\
\delta_2(u) &= 0, \quad \delta_2(v) = v;
\end{align*}$$

(11)

One can then check that the corresponding metric is the right one (the round metric).

In order to compute the operator $\langle (e - \frac{1}{2}) [D, e]^4 \rangle$ (in the tensor product by $M_4(\mathbb{C})$) we need the commutators of $D$ with the generators of $C^\infty(S^4_\theta)$. They are given by the following simple expressions,

$$\begin{align*}
[D, \alpha] &= \frac{u}{2} \{ \gamma_1 - \sqrt{-1} \sin(\phi) \gamma_3 - \sqrt{-1} \cos(\phi) \sin(\psi) \gamma_4 \}, \\
[D, \alpha^*] &= -\frac{u^*}{2} \{ \gamma_1 + \sqrt{-1} \sin(\phi) \gamma_3 + \sqrt{-1} \cos(\phi) \sin(\psi) \gamma_4 \}, \\
[D, \beta] &= \frac{v}{2} \{ \gamma_2 + \sqrt{-1} \cos(\phi) \gamma_3 - \sqrt{-1} \sin(\phi) \sin(\psi) \gamma_4 \}, \\
[D, \beta^*] &= -\frac{v^*}{2} \{ \gamma_2 - \sqrt{-1} \cos(\phi) \gamma_3 + \sqrt{-1} \sin(\phi) \sin(\psi) \gamma_4 \}, \\
[D, t] &= \frac{1}{2} \cos(\psi) \gamma_4.
\end{align*}$$

(12)

We check in particular that they are all bounded operators and hence that for any $f \in C^\infty(S^4_\theta)$ the commutator $[D, f]$ is bounded. Then, a long but straightforward calculation shows that the operator $\langle (e - \frac{1}{2}) [D, e]^4 \rangle$ is a multiple of $\gamma_5 = \gamma_1 \gamma_2 \gamma_3 \gamma_4$.

One first checks that it is equal to $\pi(c)$ where $c$ is the Hochschild cycle in (III.25) and $\pi$ is the canonical map from the Hochschild chains to operators given by

$$\pi(a_0 \otimes a_1 \otimes ... \otimes a_n) = a_0 [D, a_1] ... [D, a_n].$$

(13)

One can then check the various conditions which in the commutative case suffice to characterize Riemannian geometry $^3, ^9$.

**Theorem 3**  

a) The spectral triple $(C^\infty(S^4_\theta), \mathcal{H}, D)$ fulfills all axioms of noncommutative manifolds.

b) Let $e \in C^\infty(S^4_\theta, M_4(\mathbb{C}))$ be the canonical idempotent given in (III.25). The Dirac operator $D$ fulfills

$$\langle \left(e - \frac{1}{2}\right) [D, e]^4 \rangle = \gamma$$

where $\langle \cdot \rangle$ is the projection on the commutant of $M_4(\mathbb{C})$ and $\gamma$ is the grading operator.

The real structure $^4$ is given by the charge conjugation operator $J$, which involves in the noncommutative case the Tomita-Takesaki antilinear involution. The order one condition,

$$[[D, a], b^0] = 0 \quad \forall a, b \in C^\infty(S^4_\theta).$$

(14)

where $b^0 = J b^* J^{-1}$ follows easily from the derivation rules for the $\delta_j$.

As we shall mention in the next section, Poincaré duality continues to hold.
V Isospectral deformations

We shall show in this section how to extend Theorem 3 of the previous section to arbitrary metrics on the sphere $S^4$ which are invariant under rotation of $u$ and $v$ and have the same volume form as the one of the round metric.

We shall in fact describe a very general construction of isospectral deformations of noncommutative geometries which implies in particular that any compact spin Riemannian manifold $M$ whose isometry group has rank $\geq 2$ admits a natural one-parameter isospectral deformation to noncommutative geometries $M_\theta$. The deformation of the algebra will be performed along the lines of [23].

We let $(\mathcal{A}, \mathcal{H}, D)$ be the canonical spectral triple associated with a compact Riemannian spin manifold $M$. We recall that $\mathcal{A} = C^\infty(M)$ is the algebra of smooth functions on $M$, $\mathcal{H} = L^2(M, S)$ is the Hilbert space of spinors and $D$ is the Dirac operator. We let $J$ be the charge conjugation operator which is an antilinear isometry of $\mathcal{H}$.

Let us assume that the group $\text{Isom}(M)$ of isometries of $M$ has rank $r \geq 2$. Then, we have an inclusion

$$T^2 \subset \text{Isom}(M),$$

with $T = \mathbb{R}/2\pi\mathbb{Z}$ the usual torus, and we let $U(s), s \in T^2$, be the corresponding unitary operators in $\mathcal{H} = L^2(M, S)$ so that by construction

$$U(s) D = D U(s), \quad U(s) J = J U(s).$$

Also,

$$U(s) a U(s)^{-1} = \alpha_s(a), \quad \forall a \in \mathcal{A},$$

where $\alpha_s \in \text{Aut}(\mathcal{A})$ is the action by isometries on the algebra of functions on $M$.

We let $p = (p_1, p_2)$ be the generator of the two-parameters group $U(s)$ so that

$$U(s) = \exp(i(s_1 p_1 + s_2 p_2)).$$

The operators $p_1$ and $p_2$ commute with $D$ but anticommute with $J$. Both $p_1$ and $p_2$ have integral spectrum,

$$\text{Spec}(p_j) \subset \mathbb{Z}, \quad j = 1, 2.$$  

One defines a bigrading of the algebra of bounded operators in $\mathcal{H}$ with the operator $T$ declared to be of bidegree $(n_1, n_2)$ when,

$$\alpha_s(T) = \exp(i(s_1 n_1 + s_2 n_2)) T, \quad \forall s \in T^2,$$

where $\alpha_s(T) = U(s) T U(s)^{-1}$ as in [B].

Any operator $T$ of class $C^\infty$ relative to $\alpha_s$ (i.e. such that the map $s \rightarrow \alpha_s(T)$ is of class $C^\infty$ for the norm topology) can be uniquely written as a doubly infinite norm convergent sum of homogeneous elements,

$$T = \sum_{n_1, n_2} \hat{T}_{n_1, n_2},$$

with $\hat{T}_{n_1, n_2}$ of bidegree $(n_1, n_2)$ and where the sequence of norms $||\hat{T}_{n_1, n_2}||$ is of rapid decay in $(n_1, n_2)$.  

14
Let $\lambda = \exp(2\pi i \theta)$. For any operator $T$ in $\mathcal{H}$ of class $C^\infty$ we define its left twist $l(T)$ by
\begin{equation}
    l(T) = \sum_{n_1, n_2} \hat{T}_{n_1, n_2} \lambda^{n_2 p_1},
\end{equation}
and its right twist $r(T)$ by
\begin{equation}
    r(T) = \sum_{n_1, n_2} \hat{T}_{n_1, n_2} \lambda^{n_1 p_2},
\end{equation}
Since $|\lambda| = 1$ and $p_1, p_2$ are self-adjoint, both series converge in norm.
One has,

**Lemma 4**

a) Let $x$ be a homogeneous operator of bidegree $(n_1, n_2)$ and $y$ be a homogeneous operator of bidegree $(n'_1, n'_2)$. Then,
\begin{equation}
    l(x) r(y) - r(y) l(x) = (x y - y x) \lambda^{n'_1 n_2} \lambda^{n_2 p_1 + n'_1 p_2}
\end{equation}
In particular, $[l(x), r(y)] = 0$ if $[x, y] = 0$.

b) Let $x$ and $y$ be homogeneous operators as before and define
\begin{equation}
    x \ast y = \lambda^{n'_1 n_2} xy;
\end{equation}
then $l(x) l(y) = l(x \ast y)$.

To check a) and b) one simply uses the following commutation rule which is fulfilled for any homogeneous operator $T$ of bidegree $(m, n)$,
\begin{equation}
    \lambda^{a p_1 + b p_2} T = \lambda^{a m + b n} T \lambda^{a p_1 + b p_2}, \quad \forall a, b \in \mathbb{Z}.
\end{equation}
One has then
\begin{equation}
    l(x) r(y) = x \lambda^{n_2 p_1} y \lambda^{n'_1 p_2} = x y \lambda^{n'_1 n_2} \lambda^{n_2 p_1 + n'_1 p_2}
\end{equation}
and
\begin{equation}
    r(y) l(x) = y \lambda^{n'_1 p_2} x \lambda^{n_2 p_1} = y x \lambda^{n'_1 n_2} \lambda^{n_2 p_1 + n'_1 p_2}
\end{equation}
which gives a). One checks b) in a similar way.
The product $\ast$ defined in (11) extends by linearity to an associative product on the linear space of smooth operators and could be called a $\ast$-product.
One could also define a deformed ‘right product’. If $x$ is homogeneous of bidegree $(n_1, n_2)$ and $y$ is homogeneous of bidegree $(n'_1, n'_2)$ the product is defined by
\begin{equation}
    x \ast_r y = \lambda^{n'_1 n_2} xy.
\end{equation}
Then, along the lines of the previous lemma one shows that $r(x) r(y) = r(x \ast_r y)$.

Next, we twist the antiunitary isometry $J$ by
\begin{equation}
    \tilde{J} = J \lambda^{-p_1 p_2}.
\end{equation}
One has $\tilde{J} = \lambda^{p_1 p_2} J$ and hence
\begin{equation}
    \tilde{J}^2 = J^2.
\end{equation}
Lemma 5 For \( x \) homogeneous of bidegree \((n_1, n_2)\) one has that

\[
\tilde{J} l(x) \tilde{J}^{-1} = r(J x J^{-1}) \lambda^{-n_1 n_2}.
\] (18)

For the proof one needs to check that

\[
\tilde{J} l(x) = r(J x J^{-1}) \lambda^{-n_1 n_2} \tilde{J}.
\] (19)

One has

\[
\lambda^{-p_1 p_2} x = x \lambda^{-(p_1 + n_1)(p_2 + n_2)} = x \lambda^{-n_1 n_2} \lambda^{-(p_1 n_2 + n_1 p_2)} \lambda^{-p_1 p_2}.
\] (20)

Then

\[
\tilde{J} l(x) = J x \lambda^{-n_1 n_2} \tilde{J} = J x \lambda^{-n_1 n_2} \lambda^{-p_1 p_2},
\] (21)

while

\[
r(J x J^{-1}) \tilde{J} = J x J^{-1} \lambda^{-n_1 n_2} J \lambda^{-p_1 p_2} = J x \lambda^{-n_1 n_2} \lambda^{-p_1 p_2}.
\] (22)

Thus one gets the required equality.

We can now define a new spectral triple where both \( \mathcal{H} \) and the operator \( D \) are unchanged while the algebra \( \mathcal{A} \) and the involution \( J \) are modified to \( l(\mathcal{A}) \) and \( \tilde{J} \) respectively. By Lemma 5 b) one checks that \( l(\mathcal{A}) \) is still an algebra.

Since \( D \) is of bidegree \((0, 0)\) one has,

\[
[D, l(a)] = l([D, a])
\] (23)

which is enough to check that \([D, x]\) is bounded for any \( x \in l(\mathcal{A})\).

For \( x, y \in l(\mathcal{A}) \) one checks that

\[
[x, y^0] = 0, \quad y^0 = \tilde{J} y^* \tilde{J}^{-1}.
\] (24)

Indeed, one can assume that \( x \) and \( y \) are homogeneous and use Lemma 5 together with Lemma 4 a). Combining equation (24) with equation (23) one then checks the order one condition

\[
[D, x, y^0] = 0, \quad \forall x, y \in l(\mathcal{A}).
\] (25)

As a first corollary of the previous construction we thus get

**Theorem 6** Let \( M \) be a compact spin Riemannian manifold whose isometry group has rank \( \geq 2 \). Then \( M \) admits a natural one-parameter isospectral deformation to noncommutative geometries \( M_\theta \).

The deformed spectral triple is given by \((l(\mathcal{A}), \mathcal{H}, D)\) with \( \mathcal{H} = L^2(M, S) \) the Hilbert space of spinors, \( D \) the Dirac operator and \( l(\mathcal{A}) \) is really the algebra of smooth functions on \( M \) with product deformed to the \(*\)-product defined in (11). Moreover, the real structure is given by the twisted involution \( \tilde{J} \) defined in (16). One checks using the results of [24] and [8] that Poincaré duality continues to hold for the deformed spectral triple. We showed in [8] that the Dirac operator for the Levi-Civita connection minimizes the action functional \( \int D^{2-n} \) (where \( n \) is the dimension of \( M \)) among operators of the form \( D + T \) which \( \epsilon \) commute with \( J \) and have the same commutators as \( D \) with any \( a \in \mathcal{A} \) (so that \( T \) belongs to the commutant of \( \mathcal{A} \)). It is important to check that this continues to hold in the deformed case. This is easy to see since we...
can also assume invariance under the action \( U(s) TU(s)^{-1} = \alpha_s(T) \) so that the space of available perturbations \( T \) is smaller in the deformed case.

The above construction also allows us to extend Theorem 3 of the previous section to arbitrary metrics on the sphere \( S^4 \) which are invariant under rotation of \( u \) and \( v \) and have as volume form \( \sqrt{g} dx \) the round one.

In \[22\] Nekrasov and Schwarz showed that Yang-Mills gauge theory on noncommutative \( \mathbb{R}^4 \) gives a conceptual understanding of the nonzero B-field desingularization of the moduli space of instantons obtained by perturbing the ADHM equations \[1\]. In \[25\], Seiberg and Witten exhibited the unexpected relation between the standard gauge theory and the noncommutative one. The above work raises the specific question for NC-spheres \( S^4_\theta \) whether one can implement such a Seiberg-Witten relation as an isospectral one. It also suggests to extend the above isospectral deformations (Theorem 6) to more general compatible Poisson structures on a given spin Riemannian manifold.

VI Final remarks

We shall end this paper with several important remarks,

The odd case

First there are formulas for the odd Chern character in cyclic homology, similar to those of section II above. Given an invertible element \( u \in GL_r(\mathcal{A}) \), the component \( \text{ch}_{n+\frac{1}{2}}(u) \) of its Chern character is as above an element of

\[
\mathcal{A} \otimes \overline{\mathcal{A}} \otimes \cdots \otimes \overline{\mathcal{A}}
\]

where \( \overline{\mathcal{A}} = \mathcal{A}/\mathbb{C}1 \) is the quotient of \( \mathcal{A} \) by the scalar multiples of the unit 1.

The formula for \( \text{ch}_{n+\frac{1}{2}}(u) \) is (with \( \lambda_n \) a normalization constant),

\[
\text{ch}_{n+\frac{1}{2}}(u) = \lambda_n \left\{ \sum u_{i_0 i_1} \otimes u_{i_1 i_2}^{-1} \otimes u_{i_2 i_3} \cdots \otimes u_{i_{2n-1} i_0}^{-1} \right. \\
- \left. \sum u_{i_{0} i_1}^{-1} \otimes u_{i_1 i_2} \otimes u_{i_2 i_3}^{-1} \cdots \otimes u_{i_{2n-1} i_0} \right\}
\]

As in the even case, the crucial property of the components \( \text{ch}_{n+\frac{1}{2}}(u) \) is that they define a cycle in the \((b,B)\) bicomplex of cyclic homology,

\[
B \text{ch}_{n-\frac{1}{2}}(u) = b \text{ch}_{n+\frac{1}{2}}(u) .
\]

For any pair of integers \( m, r \) we can define the odd analogues \( B_{m,r} \) as generated by the \( r^2 \) elements \( u_{ij}; \ i,j \in \{1,\ldots,r\} \) and we impose as above the relations

\[
u u^* u = u^* u = 1 \quad u = [u_{ij}]
\]

and

\[
\text{ch}_{j+\frac{1}{2}}(\rho(u)) = 0 \quad \forall j < m .
\]
One can prove as an exercise that the suspension of the corresponding NC spaces are contained in the $Gr_{m,2r}$.

**The Dirac operator and quantum groups**

There exists formulas for $q$-analogues of the Dirac operator on quantum groups, (cf. [3], [4]); let us call $Q$ these “naive” Dirac operators. Now the fundamental equation to define the sought for true Dirac operator $D$ which we used above implicitly on the deformed 3-sphere (after suspension to the 4-sphere and for deformation parameters which are complex of modulus one) is,

$$[D]_q^2 = Q.$$  \hfill (6)

where the symbol $[x]_q$ has the usual meaning in $q$-analogues,

$$[x]_q = \frac{q^x - q^{-x}}{q - q^{-1}}. \hfill (7)$$

The main point is that it is only by virtue of this equation that the commutators $[D, a]$ will be bounded, and they will be so not only for the natural action of the algebra $\mathcal{A}$ of functions on $SU(2)_q$ on the Hilbert space of spinors but also for the natural action of the opposite algebra $\mathcal{A}^\circ$; this is easy to prove in Fourier. But it is not true that $[Q, a]$ is bounded, for $a \in \mathcal{A}$, due to the unbounded nature of the bimodule defining the $q$-analogue of the differential calculus.

**Yang-Mills theory**

One can develop the Yang-Mills theory on $S^4_\theta$ since we now have all the required structure, namely the algebra, the calculus and the “vector bundle” $e$ (naturally endowed, in addition, with a preferred connection $\nabla$). One can check that the basic results of [5] apply. In particular Theorem 4, p 561 of [5] gives a basic inequality showing that the Yang-Mills action, $YM(\nabla) = \int \theta^2 ds^4$, (where $\theta = \nabla^2$ is the curvature, and $ds = D^{-1}$) has a strictly positive lower bound given by the topological invariant $\int \gamma(e - \frac{1}{2})[D, e]^4 ds^4 = 1$. The next step is thus to extend the results of [4] on the classification of Yang-Mills connections to this situation. This was done in [7] for the noncommutative torus and in [22] for noncommutative $\mathbb{R}^4$. Note however that in the noncommutative case the NC-sphere $S^4_\theta$ is not isomorphic to the one-point compactification of noncommutative $\mathbb{R}^4$ used there. In particular, and in contrast to what happens for noncommutative $\mathbb{R}^4$, even the measure theory of $S^4_\theta$ is very sensitive to the irrationality of the parameter $\theta$.
