Ameliorative Effects of *Pseudomonas fluorescence* Strains on Growth and Antioxidant Potential of Okra (*Abelmoschus esculentus*) Plant under Nematode Infection

A. M. Esan, Z. Khan, R. Kiran, T. O. Omolekan, K. A. Aremu, and H. R.Y. Adeyemi

**ABSTRACT**

*Meloidogyne incognita* is a plant pathogen causing root-knot nematodes disease in many crops worldwide. Due to the environmental threat on the use of chemical fumigants, there is a need for a biological control method using microbial antagonists on root-knot nematodes disease. Therefore, this study was conducted to screen and evaluate the biocontrol potential of *P. fluorescens* strains against root-knot nematodes. The effectiveness of six *P. fluorescens* strains viz., Pf1, Pf2, Pf3, Pf4, Pf5, and Pf6 were tested *in vitro* and also in pots experiment for their inhibitory activities and biocontrol potential against root-knot nematodes disease caused by *Meloidogyne incognita* on okra plant. Treatments of the nematode with 1.0-6.0% concentrations of 10^6 CFU/mL of Pf4 and Pf5 strains caused 70.0-95.0% inhibition on nematode egg-hatch and 2nd stage juveniles activity. Pf3, Pf4 and Pf5 showed a decrease in the number of roots galling with increased root and shoot dry weights of stressed okra plant. Moreover, there was 25.99-36.43%, 37.76-79.145% and 42.62-62.37%, 69.83-98.09% increase in shoot length and leaf areas after 15th and 30th day respectively of *P. fluorescens* inoculation. The inoculated okra plants exhibited higher photosynthetic pigments, higher antioxidant enzymes activity and mineral contents than the nematode treated groups. Higher mineral contents were observed in the roots than the leaves of the okra plant subjected to the nematode infection. The bacteria strains especially Pf4 and Pf3 have considerable potential to reduce the menace of the nematodes in the treated okra plant. Therefore, the strains can be used for crop management against root-knot nematodes disease.

**Keywords:** Antioxidant enzymes, *Meloidogyne incognita*, Minerals, Okra, *Pseudomonas fluorescens*.

I. INTRODUCTION

Root-Knot-Nematodes are soil-borne plant pathogens responsible for various damage in vegetable crops worldwide, and they are divergent in nature [1]. There are about 97 known species of nematodes but *Meloidogyne hapla*, *Meloidogyne javanica*, *Meloidogyne incognita* and *Meloidogyne arenaria* are causative organisms for the major crop damage [2]. *Meloidogyne spp.* induce various changes around the root architecture that affect crop quality and production [3]. Giant cells formed in the root of the plants infested with nematodes provide the nutrients on which nematodes feed. This inhibits the flow of nutrients from the plant roots to aerial parts of the plant [4]. Nematodes cause a deficiency of magnesium which is a major mineral element for chlorophyll synthesis and essential element for phosphotransferases activity in the plant tissue [5], and thus, result to low chlorophyll content and low rates of photosynthesis [6]. It is difficult to control *Meloidogyne incognita* due to its adaptability in the soil and its wide host range [7], [8]. Okra is prone to various diseases and pests from germination to the harvesting stage. Among these biotic
factors, the prominent one is nematodes that reduce the quality and quantity of okra products, which is responsible for fifty percent of the overall damage [9]. Over the years, due to environmental restrictions on nematicidal use for controlling plant root-knot nematodes disease, biological control and other eco-friendly disease control measures have recently gained tremendous attention and interest in controlling root-knot nematodes [10]. Certain strains of rhizospheric microorganisms like P. fluorescens are able to suppress a variety of plant diseases caused by soil-borne plant pathogens and hence are of considerable agricultural value [11]. P. fluorescens spp promote plants growth through phytohormones production such as cytokinins, gibberellins, indole acetic acid (IAA), and antioxidant enzymes [12]. Previous studies demonstrated that P. fluorescens reduces plant infection by generating various metabolites which serve as antagonists to various soil-borne diseases [13]. Therefore, this study seeks to evaluate the potential of P. fluorescens spp on the suppression of Meloidogyne incognita J2 activity, egg mass and egg-hatch under in vitro and in vivo studies. We examined the changes in the photosynthetic pigments’ levels, antioxidant enzyme activities, growth characteristics, and mineral contents in the nematode-infested okra plants under screen house condition.

II. MATERIALS AND METHODS

A. Preparation of Nematode Inoculum

Nematodes (Meloidogyne incognita) were obtained from the roots of infected okra plants in the experimental screen house at the ICAR-NBPRG, India. The entire roots of infected plants were immersed in a beaker of 0.5 L of water to remove the soil and other debris. Meloidogyne incognita eggs were removed by handpicking or with the aid of forceps into distilled water (pH 7.0) in a petri dish through a mesh of 26 µm. Extraction of the second stage juveniles (J3) was done using a modified Baermann funnel method of Southey [14]. The inoculum of the nematode obtained was used for both in vivo and in vitro studies.

B. Preparation of P. fluorescens Culture

Six strains of P. fluorescens were procured from CSIR-Institute of Microbial Technology, Chandigarh, India. (Table I). King’s B agar medium was used for culturing of the strains which were incubated at 25 °C for 48 h. The cultures were picked and sub-cultured in King’s B agar medium to obtain pure colonies. A pure colony of each strain was inoculated on the nutrient broth and incubated at 28 °C for 48 h. Then, the culture was centrifuged at 6200 rpm for 10 min. at 4 °C, and the pellets obtained were washed twice with sterilized distilled water and then re-suspended in sterilized distilled water to an optical density of 0.8 at 600 nm (approximate cell density of 1×10^8 CFU/mL). Distilled water was used for the dilutions to test the nematicidal effect of P. fluorescens spp. against M. incognita in vitro.

C. Effect of P. Fluorescens spp. on J2 Mortality

The bacteria culture (0.5 mL) of various concentrations, ranging from 1% to 6% of 10^8 CFU/mL of each strain of P. fluorescens was placed in cavity blocks containing more than 10 active J2 of Meloidogyne incognita. The active J2 of Meloidogyne incognita were kept in distilled water as a control and in a nutrient broth that contained no bacterium and also in nutrient broth with bacteria for determining the LC50 (lethal concentration which causes 50% J2 mortality) for 24 h after exposure. After incubation of the active J2 of Meloidogyne incognita in the nutrient broth solution contained bacteria cells. J2 mortality was observed for 5 days using a binocular microscope. J2 were considered dead if they were immobile with a straight structure when touched with a pricking needle. The experiment was in complete randomized design with three replicates.

D. Pot Experiment

The seeds of okra (genotype NHe-47-4) were procured from ICAR-NBPRG, India. The seeds were sterilized using 0.1% sodium hypochlorite for about 2 min, washed in distilled water and five seeds per pot were planted in 10 kg of sterilized soil in pots with intermittent irrigation to achieve soil water field capacity for the period of the experiment. After two weeks of germination, the seedlings were inoculated with 5 mL of M. incognita J2 suspension in water per pot. For inoculation, roots were exposed and the freshly hatched M. incognita J2 were introduced with the use of a pipette around the seedling roots and then covered with the soil. Similarly, the bacterial strains (Pf3, Pf4 and Pf5) which showed positive results in in vitro studies were examined under pot experiment in a screen house for the biocontrol potency against M. incognita. After two days of nematode inoculation, 1 mL (10^8 CFU/ mL) of broth solution of the bacteria strains was directly introduced around the roots of okra plant. The treatment sets followed a complete randomized design:

1. Control groups:
   a. Normal control (no nematode, no broth, and no bacterium);
   b. The broth only (positive control);
   c. Nematode only (negative control).

2. P. fluorescens groups:
   a. Pf3;
   b. Pf4;
   c. Pf5.

3. P. fluorescens groups + Nematodes groups:
   a. Pf3 + Nematodes;
   b. Pf4 + Nematodes;
   c. Pf5 + Nematodes.

E. Vegetative Growth Characters and Root Physiology

After 3 and 6 weeks’ inoculation of active M. incognita J2 into the soil, growth parameters were estimated from each experimental group. Root physiology was examined through visual means using random plants from each treatment at the end of the experiment.

F. Photosynthetic Pigments Estimation

The photosynthetic pigments of the okra leaves were determined by using the method of Sukran et al. [15]. A 250 mg of okra leaves were homogenized with the use of mortar and pestle in 85% acetone for about 5 min. Centrifugation of the homogenate was done using cold centrifuge at 6000 rpm for 10 min. Estimation of the extract concentration was done using pure 85% aqueous acetone as a blank in UV/VIS
spectrophotometer at three wavelengths of 663, 644 and 452 nm for the carotenoids, chlorophyll a and chlorophyll b.

G. Mineral Concentrations Determination

1. Sodium content

The sodium content of digested powder was estimated by using a flame photometer and expressed in mg/g by using the method of Jackson [16].

2. Phosphorus, calcium, and magnesium contents

The phosphorus content of the okra leaf was estimated and expressed in milligram per gram by using the method of Jackson [16].

3. Potassium content

Potassium content in the plant samples was estimated by using a flame photometer (models PPP7 and PFP7/C JENWAY) and expressed in milligram per gram according to the method of Jackson [16].

4. Zinc and iron contents

The zinc and iron contents of the samples were estimated by using an Atomic Absorption spectrophotometer (PerkinElmer UV-Vis Model) and expressed in milligram per gram according to the method of Esfandiari et al. [18].

H. Antioxidant Enzyme Assays

1. Enzyme extraction

A 1 g of okra leaf was ground in a 10 mL solution of 0.1 M potassium phosphate (K2HPO4) buffer and 0.5 mM ethylene diamine tetra acetic acid (EDTA). The leaf homogenate was centrifuged for 20 min at 15,000 rpm in a 4°C centrifuge, and the supernatant was used for enzyme analysis according to the method of Rotruck et al. [19].

2. Glutathione peroxidase assay

Estimation of the glutathione peroxidase activity was done by using the method of Dhindsa et al. [20].

3. Superoxide dismutase assay

Estimation of the superoxide dismutase activity was done by using the method of Dhindsa et al. [20].

4. Catalase assay

Estimation of the catalase activity was done by using the method of Chen et al. [21].

I. Statistical Analysis

Data on percentage growth inhibition and mortality reduction percentage were analysed using ANOVA with the Statistical Package for the Social Sciences (SPSS, 2003), followed by Least Significance Difference and the values are expressed as mean ± standard deviation using Microsoft Excel package. A significant difference was applied at p < 0.05.

III. RESULTS

A. Nematicidal Effect of P. fluorescens on J2 Mortality and on Hatching of the Egg Mass

In Fig. 1, mortality of the 2nd stage juveniles (J2) of the root-knot nematode was observed after 24 h at 6% concentration of Pf3 strain and after 24 h at 3% concentration of Pf4 strain when compared with Pf5 strain, broth only and control group.

In Fig. 2, Treatments of the root-knot nematode with 1.0-6.0% concentrations (108 CFU/mL) of Pf4 and Pf5 strains caused 70.0-95.0% inhibition of hatching of eggs in the root-knot nematode as compared with Pf3 strain and control groups. On egg mass for egg hatchability, only Pf4 and Pf5 at 1% and 6% concentrations respectively completely inhibited egg hatching after 5 days of treatment as compared with control group, where all eggs hatched out after 5 days of treatment.

Fig. 1. Culture concentrations of different strains of P. fluorescens required for LC50 of M. incognita J2 24 h after inoculation. (A) effect of broth only (B) effect of distilled water only (C) effect of Pf1 at 6% concentration (D) effect of Pf3 at 3% concentration.

Fig. 2. Images showing the inhibitory effect of P. fluorescens on hatching of the egg masses after 5 days of treatment (A) effect of broth only (B) effect of distilled water only (C) effect of Pf4, at 1% concentration (D) effect of Pf5 at 6% concentration.
(Table I). In the same vein, after 30 days of inoculation, only Pf5 strain treated plants showed 62.37% and 98.09% increase in the shoot length and leaf areas of okra plant respectively (Table II). In Table III, a significant effect of P. fluorescens on growth parameters of okra plants infected with nematode was observed in Pf3+Nematode and Pf5+Nematode, respectively when compared with the nematode-treated group.

C. Effects of P. fluorescens and M. incognita on Photosynthetic Pigments of the Okra Plant

In Fig. 4, a decrease content of the photosynthetic pigments of okra plants was observed in the nematode-treated group. However, in Fig. 5, treatment with P. fluorescens showed a significant increase in the content of photosynthetic pigments of okra plants as compared to the control group. The nematode had a negative effect on the photosynthetic pigment content of okra plant, but treatment with P. fluorescens reduced this negative effect through an increase in the levels of chlorophyll contents in the okra plants with a significant increase observed in Pf3 when compared to the nematode-treated group (Fig. 5).
D. Effects of P. fluorescens and Nematode on Mineral Contents of the Okra Plant

In Table IV, and V, the levels of magnesium, calcium, potassium, sodium, zinc, phosphorous, and iron are shown to have increased generally in the and roots of the okra plant treated with Pf3 strain as compared to other strains and the control groups. Root-knot nematodes caused a significant reduction in the root minerals content levels. However, inoculation of P. fluorescens strains increased minerals content in the roots of the infected okra. Treatment with Pf3 strain showed a significant increase in mineral levels in the okra plant as compared to the nematode-treated groups. Inoculation of Pf3 and Pf4 strains showed significant increase of minerals content in the leaves of okra plants as compared to Pf5 strain and other groups. Combined effects of P. fluorescens and root-knot nematodes on the mineral contents were observed to be higher in the leaves of okra plants inoculated with Pf3 and Pf4 strains. Relatively, higher mineral concentrations were observed in the roots than the leaves of nematode infected okra plants (Table IV and V).

E. Effect of P. fluorescens on Antioxidant Enzymes Activity of Okra Plants Treated with the Nematode.

Antioxidant enzymes activity increased in the tissue of okra plant with P. fluorescens and nematodes (Fig. 5). A reduction in catalase activity was observed in the okra plant treated with the nematodes.

IV. DISCUSSION

This present work focused on the potential of *P. fluorescens* on nematode diseases in okra (*Abelmoschus esculentus*) plant. *P. fluorescens* at varying culture concentrations reduced the population of *M. incognita*. Bacteria cultures could have contributed to reduced hatchability of the eggs, root galling and activities of 2nd stage juveniles (*J₂*) activity. This observation was in concordance with the study of Elyour [22]; Anita et al. [23]. It was observed that the okra plant inoculated with *P. fluorescens* showed improved growth and development as compared with okra plant infected with *Meloidogyne incognita* only. Shankat et al. [24] showed that *P. fluorescens* inhibited the penetration of *Meloidogyne javanica* into tomato plants. San and Shaukat [25] also reported the biocontrol potential of the rhizobacteria against root-knot nematodes.

Increases in the shoot length and leaf area of okra plants as compared to control when *P. fluorescens* was added was observed in the soil after 15 and 30 days following inoculation may be due to phosphate solubilization, indoleacetic acid, and protease enzyme produced by *Pseudomonas* spp. [26]. The previous report revealed that indole acetic acid synthesis was correlated to the growth of plant stimulation by microorganisms [27]. Siddiqui and Shaukat [28]; Davies et al. [29] observed the induced systemic resistance of *P. fluorescens* in tomato roots against *M. javanica*. The reduction in the content of the photosynthetic pigments of okra plant under the influence of nematodes could be a result of oxidative stress induced by the nematode infection on the plant, that causes loss of photosynthetic pigments. This observation was in tandem to the report of Karpinski et al. [30] that showed damage to the plant leaf and the chloroplast by the environmental (biotic and abiotic) factors. The significant reduction of the mineral concentrations in the leaves of nematode-inoculated plants could be attributed to the reduction observed in the photosynthetic pigments, which in turn leads to the reduction of plant photosynthetic efficiency. Xu et al. [31] reported a similar result on the reduction in the contents of the nitrogen and phosphorus in cucumber leaves under higher inoculation of nematodes. The higher concentrations of minerals in the roots than in the leaves of the okra plants could be a result of disruption of the root vascular system by the nematodes, which in turn reduces the transport and uptake of the nutrients through the roots to the shoots. Therefore, the application of *P. fluorescens* may possibly increase the reactive oxygen species scavenging enzymes, and thus enhance chlorophyll and mineral contents of the okra plants under the influence of nematodes. Hence, high antioxidant enzyme activities could be interpreted as a higher tolerance of okra plant to oxidative stress caused by the nematode. The alteration in the antioxidant enzyme activities is correlated to the tolerance of the plant to the oxidative stress. Lee et al. [32] reported similar observations. The study of Mittler [33] revealed variations in the levels of antioxidant enzymes which is a signal for the ability to scavenge free reactive oxygen species.

V. CONCLUSION

*Meloidogyne incognita* is an economically important nematode that reduces food security on most cultivated plants, particularly vegetable crops worldwide. *P. fluorescens* is able to mitigate the negative effect of nematode disease on okra plant caused by *Meloidogyne incognita* through reduction of gall numbers on the roots when applied as a soil drench. The result also revealed an increase in plant growth parameters, chlorophyll content, the activity of antioxidant enzymes, and reduced gall index in the nematode infected plants. Our study suggests that Pf4 and Pf3 bacterial strains of *P. fluorescens* have considerable potential to reduce the menace of the nematodes in the soil. Furthermore, the strains of *P. fluorescens* can be used for crop management against root-knot nematodes stressed okra plants in the field conditions.

ACKNOWLEDGEMENTS

We are grateful to the director of RTF DCS of Centre for Science & Technology of Non-Aligned and Other Developing Countries (NAM S&T Centre) and ICAR-National Bureau of Plant and Genetic Resources, Pusa Campus, New Delhi, India for their constant support throughout this research work.

CONFLICT OF INTEREST

Authors have no conflict of interests whatsoever.

FUNDING

The authors appreciate financial support by RTF-DCS FELLOWSHIP INDIA grant # NAM – 05/74/2016.
