(Dated: September 10, 2019)

The speed of information propagation is finite in quantum systems with local interactions. In many such systems, local operators spread ballistically in time and can be characterized by a “butterfly velocity”, which can be measured via out-of-time-ordered correlation functions. In general, the butterfly velocity can depend asymmetrically on the direction of information propagation. In this work, we construct a family of simple 2-local Hamiltonians for understanding the asymmetric hydrodynamics of operator spreading. Our models live on a one dimensional lattice and exhibit asymmetric butterfly velocities between the left and right spatial directions. This asymmetry is transparently understood in a free (non-interacting) limit of our model Hamiltonians, where the butterfly speed can be understood in terms of quasiparticle velocities.

I. INTRODUCTION

Understanding the quantum dynamics of thermalization in isolated many-body systems is a topic of central interest. While memory of a system’s initial conditions is always preserved under unitary dynamics, this information can get “scrambled” and become inaccessible to local measurements, thereby enabling local subsystems to reach thermal equilibrium \cite{1–4}. This scrambling can be quantified by studying the spatial spreading of initially local operators under Heisenberg time evolution. Under dynamics governed by a local time-independent Hamiltonian $H$, an initially local operator near the origin, $A_0$, evolves into $A_0(t) = e^{iHt}A_0e^{-iHt}$. As $A_0(t)$ spreads in space, it starts to overlap with local operators $B_x$ at spatially separated locations $x$. The effect of scrambling is thus manifested in the non-commutation between $A_0(t)$ and $B_x$, which can be quantified via an out-of-time-ordered correlator (OTOC): \cite{5–52}

$$C(x, t) = \Re \langle A_0^\dagger(t)B_x^\dagger A_0(t)B_x \rangle$$

$$= 1 - \frac{1}{2}\langle [A_0(t), B_x]^0 [A_0(t), B_x] \rangle,$$  

where $A_0, B_x$ are local unitary operators, $\Re$ represents the real part, and the expectation value $\langle \rangle$ is with respect to the infinite temperature thermal ensemble.

The OTOC is expected to exhibit the following features in systems with scrambling dynamics \cite{6, 7, 11, 17, 19, 24, 53–67}: At early times, $A_0(t)$ approximately commutes with $B_x$ and the OTOC is nearly equal to one. At late times, $A_0(t)$ becomes highly non-local and spreads across the entire system, and the OTOC decays to zero \cite{11, 14, 21, 25}. At intermediate times, the operator has most of its support within a region around the origin defined by left and right operator “fronts” that propagate outwards, and generically also broaden in time \cite{58, 59}. As the operator front approaches and passes $x$, the OTOC $C(x, t)$ decays from nearly one to zero. We will restrict ourselves to translationally invariant systems where operators spreads ballistically with a butterfly speed $v_B$, which is similar in spirit to the Lieb-Robinson speed \cite{68} characterizing the speed of information propagation. In these cases, the operator fronts define a “light-cone” within which the OTOC is nearly zero.

A set of recent papers illustrated that the butterfly velocity can depend on the direction of information spreading \cite{69, 70}. In one dimension, the asymmetry between the different directions can be quantified by the butterfly speeds $v_B^r$ and $v_B^l$, where the superscript $r$ ($l$) represent propagation directions to the right (left). While Ref. \cite{69} showed how this asymmetry could be induced by anyonic particle statistics, Ref. \cite{70} constructed models of asymmetric unitary circuits, and Hamiltonians inspired from such circuits.

In this work, we present a complementary and physically transparent way for constructing a family of Hamiltonians with asymmetric information propagation. Our construction does not rely on particle statistics, nor is it inspired by unitary circuits. Instead, we start with non-interacting integrable spin 1/2 models where the butterfly speed is related to quasiparticle propagation velocities and can be analytically calculated \cite{66, 67, 71, 72}. We show how the butterfly speed can be made asymmetric in such models, before generalizing to non-integrable Hamiltonians by adding interactions.

II. INTEGRABLE HAMILTONIANS

In this section, we construct time-independent integrable Hamiltonians for spin 1/2 degrees of freedom living on an infinite one dimensional lattice. The Hamiltonians only have local terms acting on 2 spins at a time. These models are exactly solvable, so the butterfly velocities can be analytically calculated, and demonstrated to be asymmetric. This family of Hamiltonians parameter-
ized by \( \lambda \) takes the form:

\[
H_{\lambda} = -\frac{J(1-\lambda)}{2} \sum_j \left[ h_{yz} \sigma^y_j \sigma^y_{j+1} + h_{zy} \sigma^y_j \sigma^y_{j+1} \right] \\
-\frac{J}{2} \sum_j \left[ h_{zz} \sigma^z_j \sigma^z_{j+1} + h_x \sigma^x_j \right],
\]

where \( \sigma^x_j, \sigma^y_j, \sigma^z_j \) are the Pauli spin 1/2 operators located at site \( j \), \( J > 0, h_{xx}, h_{xy}, h_{yy} \) are constants, and the parameter \( \lambda \) lies in the range \([0, 1]\). This model can be mapped to a system of free fermions via a Jordan Wigner representation. When \( \lambda = 1 \), the Hamiltonian is the well known transverse Ising model with inversion symmetry about center of the chain. On the other hand, for \( \lambda < 1 \), the Hamiltonian does not have inversion symmetry when \( h_{yz} \neq h_{zy} \).

In order to detect the ballistic light cone and asymmetric butterfly velocities, we consider the OTOCs

\[
C_{\mu\nu}(j, t) = \mathcal{R} \left( \sigma^\mu_j(t) \sigma^\nu_{j+1}(t) \right)_{\beta=0},
\]

where \( \mu, \nu \in \{x, y, z\} \) and \( \beta = 0 \) represents the infinite temperature thermal state. We note that the mapping to free fermions allows Pauli operators to be written in terms of Majorana fermion operators which, in turn, allows an exact calculation of the OTOC (Appendix A). These OTOCs are shown in FIG. (1). For the case of \( \lambda = 0 \), the right and left butterfly velocities are equal to each other despite the lack of inversion symmetry (top panel). For \( \lambda = 1 \), the Hamiltonian \( H_1 \) is the well-known Ising model and butterfly velocities are symmetric, as shown in the middle panel of FIG. 1. By contrast, for the general case \( \lambda \in (0, 1) \), the Hamiltonian does not have inversion symmetry and the OTOCs show asymmetric butterfly velocities (lower panel).

The asymmetry in butterfly speeds for \( 0 < \lambda < 1 \) can be directly understood using the quasiparticle description of the free model. It is known that the butterfly speed in an integrable model is the maximum quasiparticle group velocity \([66, 67, 72]\), and the operator fronts generically broaden either diffusively or sub-diffusively depending on whether the integrable system is interacting or not \([72]\).

The quasi-particle dispersion for the Hamiltonian in Eq. (2) is \( \epsilon_{\lambda,1(2)}(q) = J \left( (1-\lambda)(h_{yz} - h_{zy}) \sin q + (-)(1-\lambda)^2(h_{yz} + h_{zy})^2 \sin^2 q + \lambda^2(h_{zz}^2 + h_x^2 - 2h_{zz} h_x \cos q) \right)^{1/2} \). The butterfly speed to the right (left) is the magnitude of the maximal (minimal) quasi-particle group velocity \([66, 67, 72]\)

\[
v_{B,\lambda}^r = \max_q \frac{d \epsilon_{\lambda,1(2)}(q)}{dq}, \quad v_{B,\lambda}^l = -\min_q \frac{d \epsilon_{\lambda,1(2)}(q)}{dq}.
\]

These are plotted in FIG. (2), where asymmetric butterfly velocities are clearly observed when \( \lambda \in (0, 1) \). For the special cases of \( \lambda = 0 \) and \( \lambda = 1 \), the right and left butterfly speeds are the same

\[
v_{B,0}^r = v_{B,0}^l = 2J \max(|h_{yz}|, |h_{zy}|), \quad v_{B,1}^r = v_{B,1}^l = J \min(|h_{zz}|, |h_x|).
\]

The above results are consistent with the butterfly velocities demonstrated via the out-of-time-ordered correlations shown in FIG. (1).

**III. NON-INTEGRABLE HAMILTONIANS**

In this section, we construct non-integrable Hamiltonian by adding longitudinal fields to the free Hamiltonian \( H_\lambda \) \([64, 65]\). The asymmetric butterfly velocities are estimated from a variety of measures including out-of-time-ordered correlations, right/left weight of time-evolved operators, and operator entanglement.

The interacting Hamiltonian on a one dimensional lattice with open boundary conditions is

\[
H = -\frac{J(1-\lambda)}{2} \sum_{j=1}^{L-1} \left[ h_{yz} \sigma^y_j \sigma^y_{j+1} + h_{zy} \sigma^y_j \sigma^y_{j+1} \right] \\
-\frac{J}{2} \left[ h_{zz} \sum_{j=1}^{L-1} \sigma^z_j \sigma^z_{j+1} + \sum_{j=1}^{L} \sigma^z_j \right] - \frac{J}{2} \left[ \sum_{j=1}^{L} h_z \sigma^z_j \right],
\]

where \( L \) is the system size, and \( h_z \) is a longitudinal field strength. We select the particular parameters \( \lambda = 0.5, h_{yz} = 0.5, h_{zy} = -0.25, h_{zz} = 1.0, h_x = -1.05, h_z = \).
0.5, although none of our results are fine tuned to this choice.

The longitudinal field breaks integrability and is expected to thermalize the system. For non-integrable Hamiltonians with thermalizing dynamics, the level statistics is consistent with the distribution of level spacings in random matrix ensembles [73]. Let $E_0 < \cdots < E_n < E_{n+1} < \cdots$ be the sequence of ordered energy eigenvalues and $s_n = (E_{n+1} - E_n)$ be the level spacings. One defines the ratio of consecutive level spacings $r_n = s_n / s_{n-1}$, and the distribution of $r_n$ can be described by the Wigner-like surmise for non-integrable systems [74, 75]

$$p_W(r) = \frac{1}{Z_W} \frac{(r + r^2)^W}{(1 + r + r^2)^{1+3W/2}},$$

where $W = 1, Z_1 = 8/27$ for Gaussian Orthogonal Ensemble (GOE), and $W = 2, Z_2 = 4\pi/(81\sqrt{3})$ for Gaussian Unitary Ensemble (GUE), while they are Poisso-

Figure 2. Quasi-particle dispersion relations $\epsilon_{\lambda,1}(q)$ (upper panel) and asymmetric butterfly speeds (lower panel) for the Hamiltonian $H_{\lambda}$ [Eq. (2)]. The parameters used are $h_y = 0.5, h_x = -0.25, h_z = 1.0, h_k = -1.05$. In the upper panel, the star $*$ denotes the place where the dispersion relation has maximal or minimal slope, and the solid lines represent the slope. In the lower panel, asymmetric butterfly speeds are directly determined from the quasi-particle dispersion relations [Eq. (4)].

Figure 3. The histogram of the ratio of consecutive level spacings. It is computed from 32708 all energy eigenvalues of the Hamiltonian [Eq. (7)] with parameters $\lambda = 0.5, h_y = 0.5, h_x = -0.25, h_z = 1.0, h_k = -1.05, h_\lambda = 0.5$, and length $L = 15$.

We now characterize the asymmetric spreading of quantum information in this model using a variety of different diagnostics that were discussed in [70].

### A. Asymmetric butterfly velocities from OTOCs

In this subsection, we estimate the asymmetric butterfly velocities from OTOCs.

As discussed earlier, as the time-evolved operator spreads ballistically, OTOCs can detect the light cone and butterfly velocities. The saturated value of OTOCs equals approximately one outside the ballistic light cone and zero inside it. Near the boundary of the light cone, the OTOCs decay in a universal form $C(j, t) \sim -e^{-(j - v_B t)/v_t}$, where $c, f$ are constants, $v_B$ describes the speed of operator spreading, and $\alpha$ controls the broadening of the operator fronts. In a generic “strongly quantum” system (i.e., away from large $N$/semiclassical/weak coupling limits) the operator front shows broadening which corresponds to $\alpha > 1$ so that the OTOC is not a simple exponential in $t$ [67].

Nevertheless, the decay can still look exponential along rays $j = vt$ in spacetime, $C(j = vt, t) = 1 - f e^{-\lambda(\alpha) t}$, defining velocity-dependent Lyapunov exponents (VDLEs) which look like $\lambda = -c(v - v_B)^2$ near
First, as shown in FIG. (4), we observe asymmetric butterfly velocities in relatively large systems with \( L = 41 \) spins. In our numerical calculations, we use the time-evolving block decimation (TEBD) algorithm after mapping matrix product operators to matrix product states [76–78], which is able to efficiently simulate the evolution of operators in the Heisenberg picture. The OTOCs shown in FIG. (4) clearly demonstrate asymmetric butterfly velocities.

Second, we estimate the asymmetric butterfly velocities from the extracted VDLEs \( \lambda(v) \sim -c(v-v_B)^{\alpha} \). Because of the limited computational resources for exact diagonalization, the right and left butterfly velocities are measured by setting the initial local operator at the boundary \( j = 1 \) and \( j = L \) respectively. In FIG. (5), the OTOCs exponentially decay along the rays with different speed \( C(1 + x_r, x_r/v) = 1 - |\sigma_1^r(x_r/v)\sigma_{1+r,x}^r|^{\beta=0} \) and \( C(L-x_l, x_l/v) = 1 - |\sigma_1^l(x_l/v)\sigma_{1-x_l}^l|^{\beta=0} \). For a given velocity \( v \), \( \lambda(v)/v \) is the slope of logarithm of the left and right propagating OTOCs versus the distance \( x \). After extracting the VDLEs \( \lambda(v) \) from the OTOCs, here we give a rough estimation of the butterfly velocities via fitting the curve \( \lambda(v) \sim -c(v-v_B)^{\alpha} \). In FIG. (6), we obtain the results \( v_B^{\ast} \sim 0.29J \) and \( v_B^{\ast} \sim 0.66J \).

FIG. 6. VDLEs fitted from the left and right propagating OTOCs in FIG. (5) with the slope equaling \( \lambda(v)/v \). The parameters \( c, v_B, \alpha \) can be fitted via the least square method. Here the results of fitting the last 7 points are \( v_B^{\ast} \sim 0.29J, \alpha^{\ast} \sim 1.52 \), and \( v_B^{\ast} \sim 0.66J, \alpha \sim 1.61 \).

### B. Asymmetric butterfly velocities from right/left weights

Now we turn to the analysis of asymmetric butterfly velocities directly measured from right and left weights of the spacial spreading operators.

To define the right/left weight, note that every operator in a spin 1/2 system with length \( L \) can be written in the complete orthogonal basis of \( 4^L \) Pauli strings \( S = \otimes_{j=1}^{L} S_j \), i.e. \( O(t) = \sum_S a_S(t)S, \) where \( S_j = I, \sigma^x, \sigma^y \) or \( \sigma^z \). Unitary evolution preserves the norm of operators, so \( \sum_S |a_S(t)|^2 = 1 \) holds for a normalized operator. The information of operator spreading is contained in the coefficients \( a_S(t) \). In order to describe the spatial spreading, the right weight is defined by

\[
\rho_r(j,t) = \sum_{S:S_j \neq I,S_j \neq j} |a_S(t)|^2, \tag{9}
\]

where the left weight is defined analogously. Because of the conservation of operator norm \( \sum_j \rho_r(j,t) = 1 \), the weight can be interpreted as an emergent local conserved density for the right/left fronts of the spreading operator.

Recent studies [58–61] showed that the hydrodynamics for the right/left weight can be characterized by a biased diffusion equation in non-integrable systems, which means that the front is ballistically propagating with diffusively broadening width. Thus, when the time-evolved operator spreads, \( \rho_r \) moves to the right with velocity \( v_B^{\ast} \), and \( \rho_l \) moves to the left with velocity \( v_B^{\ast} \).

Here in the numerical calculations of exact diagonalization, the right and left weights are obtained by setting the initial local operator at the boundary \( j = 1 \) and \( j = L \) respectively. The right weight \( \rho_r(1 + x_r,t) \) of \( \sigma_1^r(t) \) is calculated in order to compare the left weight \( \rho_l(L - x_l,t) \) of \( \sigma_1^l(t) \), where \( x_r(x_l) \) is the distance between the right

\[ v_B \] The VDLEs provide more information about the operator spreading than the butterfly velocities alone.
C. Asymmetric butterfly velocities from the operator entanglement growth

In this subsection, the growth of operator entanglement is investigated to estimate the asymmetric butterfly velocities.

The entanglement of time-evolved operators encodes information about its spatial spreading. Refs. [70, 79] discussed a coarse-grained hydrodynamic description for the entanglement dynamics of a spreading operator under Heisenberg time evolution. Let \( \hat{S}(t, x) \) be the operator entanglement across bond \( x \) at time \( t \). To leading order, its growth depends on the local entanglement gradient

\[
\frac{\partial \hat{S}}{\partial t} = 2 s_{eq} \Gamma \left( \frac{1}{2} \frac{\partial \hat{S}}{\partial x} \right),
\]

where \( s_{eq} \) is the equilibrium entropy density at infinite temperature, and \( \Gamma(s) \) is a non-negative growth function. Let us discuss the properties of the growth function \( \Gamma(s) \). First, the growth function equals zero in equilibrium. In thermal equilibrium at infinite temperature, the operator entanglement \( \hat{S}(t, x) \) has a pyramid shape \( \hat{S}(t, x) = 2 s_{eq} \min \{ x, L - x \} \) in a one-dimensional system of length \( L \). Thus, \( \Gamma(s_{eq}) = \Gamma(-s_{eq}) = 0 \) is satisfied.

Second, the butterfly velocities are given by the derivatives \( v_B^r = -s_{eq} \Gamma'(s_{eq}) \) and \( v_B^l = s_{eq} \Gamma'(-s_{eq}) \). Thus, this function \( \Gamma(s) \) provides yet another way of obtaining butterfly velocities, and it follows that any \( \Gamma(s) \) with asymmetries at its endpoints will have asymmetric butterfly speeds. FIG. (8) shows the growth of operator entanglement across different spatial cuts in time, showing the system approaching the late time equilibrium pyramidal shape.

The statements above are obtained from a 'minimal curve picture of Ref. [79], i.e. the entanglement \( \hat{S}(t, x) \) is the minimum of the sum of the initial entanglement \( \hat{S}(0, y) \) and the integral of a velocity-dependent line tension \( \mathcal{E}(v) \). The minimal curve is a straight line with constant velocity \( v = (x - y)/t \), so that \( \hat{S}(t, x) = \min_y \left( s_{eq} \mathcal{E}(x-y/t) + \hat{S}(0, y) \right) \). Then one can get the growth function is \( \Gamma(s) = \min_v \left( \mathcal{E}(v) - v s/s_{eq} \right) \), where \( s \) is between \( -s_{eq} \) and \( s_{eq} \). Applying the inverse Legendre transformation, the line tension can be expressed as \( \mathcal{E}(v) = \max_v \left( \Gamma(s) + v s/s_{eq} \right) \). The line tension captures the leading-order hydrodynamics of operator spreading, and the left/right butterfly speeds can be obtained from the intersections of the line tension and the velocity

\[
\mathcal{E}(v_B^r) = v_B^r, \quad \mathcal{E}(v_B^l) = v_B^l.
\]
the center of the system.

Y.-L.Z. is supported by the National Science Foundation for helpful discussions. VK thanks Charles Cheng-Ju Lin for helpful discussions. VK thanks Charles and non-integrable Hamiltonians with asymmetric ballistic information spreading. Exact solutions of the butterfly velocities are obtained in the integrable models. The asymmetric butterfly velocities are estimated from different quantities characterizing operator spreading including out-of-time-ordered correlations, right/left weight of time-evolved operators, and operator entanglement.

Given the constructions and studies in this paper, several open questions would be interesting to explore in the future work. Here we have focused on the information spreading at infinite temperature. How does the asymmetric spreading change at finite temperature? Additionally, it is worth studying how asymmetries encoded in various quantities are intertwined with each other. For example, does the transport of conserved quantities (like energy) inherit the same signatures of asymmetry as the spreading of local operators? Is it possible to disentangle them? Finally, probing the asymmetry of information spreading may also interesting to explore in many-body localized systems or disordered systems with Griffiths effects, where the butterfly velocities are zero and the light cones are logarithmic or subballistic.

IV. CONCLUSION AND DISCUSSION

In summary, we have constructed 2-local integrable and non-integrable Hamiltonians with asymmetric ballistic information spreading. Exact solutions of the butterfly velocities are obtained in the integrable models. The asymmetric butterfly velocities are estimated from different quantities characterizing operator spreading including out-of-time-ordered correlations, right/left weight of time-evolved operators, and operator entanglement.

FIG. 8. Operator entanglement of the time-evolved Pauli operator $\sigma_i^{(L+1)/2}(t)$ in the non-integrable Hamiltonian $H$ [Eq. (7)] with parameters $\lambda = 0.5, h_y = 0.5, h_x = -0.25, h_z = 1.0, h_x = -1.05, h_z = 0.5$, and length $L = 13$. The times are $t = 4, 8, \ldots, 36, 40$ and 400 with unit $1/J$. The dotted line is the center of the system.

FIG. 9. Effective line tension $E_{\text{eff}}(v)$ of the Hamiltonian $H$ [Eq. (7)] with parameters $\lambda = 0.5, h_y = 0.5, h_x = -0.25, h_z = 1.0, h_x = -1.05, h_z = 0.5$, and length $L = 12$ (upper panel) and $L = 13$ (lower panel). Here $(x+y)/2$ is located at the center of the chain to minimize boundary effects, the velocity is $v = (x-y)/t$, and the unit of time is $1/J$.

APPENDIX A: ANALYTIC SOLUTION OF TIME-EVOLVED OPERATORS AND OTOCS IN THE FREE MODEL

The Jordan Wigner mapping allows spin operators to be written in terms of free Majorana fermions as follows: $\sigma_i^x = i\gamma_{2j}\gamma_{2j+1}$, $\sigma_i^y = (\prod_{k=-\infty}^{t-1}i\gamma_{2k}\gamma_{2k+1})\gamma_{2j}$, and $\sigma_i^z = (\prod_{k=-\infty}^{t-1}i\gamma_{2k}\gamma_{2k+1})\gamma_{2j+1}$. Below, we obtain analytic solutions for time-evolved operator for this Hamiltonian [Eq. (2)] within the Heisenberg picture. Denoting $\gamma_0(t) = \sum_n f_n(t)\gamma_n$ and $\gamma_1(t) = \sum_m h_m(t)\gamma_m$, the time-evolved operator is $\sigma_{01}(t) = i\gamma_0(t)\gamma_1(t) =$
where the initial condition is \( f_n(t) = \delta_{n,0} \). After applying the Fourier transformation \( f_{2n}(t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} dq e^{-i n q} A(q,t), f_{2n+1}(t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} dq e^{-i n q} B(q,t), \)

we get:

\[
\begin{align*}
\left\{ \frac{\partial A(q,t)}{\partial t} \right\} & = \lambda |J|_{x} - h_{zz} e^{-i q} |B(q,t) + (1 - \lambda) 2 i J h_{yz} \sin(q) A(q,t), \left\{ \frac{\partial B(q,t)}{\partial t} \right\} = \lambda |J|_{x} - h_{zz} e^{-i q} |A(q,t) - (1 - \lambda) 2 i J h_{yz} \sin(q) B(q,t). \end{align*}
\]

Then the analytic solution is:

\[
\begin{align*}
f_{2n}(t) & = \frac{1}{2\pi} \int_{-\pi}^{\pi} dq e^{-i n q} \lambda |J|_{x} - h_{zz} e^{-i q} \left( 1 \right) \\
f_{2n+1}(t) & = \frac{1}{2\pi} \int_{-\pi}^{\pi} dq e^{-i n q} \lambda |J|_{x} - h_{zz} e^{-i q} \left( 2 \right) \times \frac{1}{\epsilon_{\lambda,1} - \epsilon_{\lambda,2}}.
\end{align*}
\]

where \( \epsilon_{\lambda,1(2)}(q) = J \left[ (1 - \lambda)(h_{yz} - h_{zy}) \sin q + \epsilon \right] (1 - \lambda)^2 (h_{yz} + h_{zy})^2 \sin^2 q + \lambda^2 (h_{zz}^2 + h_x^2 - 2 hzz h_x \cos q)^{1/2} \right) \]. Similarly the coefficients in the exact solution \( \gamma_1(t) = \sum h_n(t) \gamma_m \) are:

\[
\begin{align*}
h_{2m}(t) & = \frac{1}{2\pi} \int_{-\pi}^{\pi} dq e^{-i n q} \lambda |J|_{x} - h_{zz} e^{-i q} \left( 1 \right) \\
h_{2m+1}(t) & = \frac{1}{2\pi} \int_{-\pi}^{\pi} dq e^{-i n q} \lambda |J|_{x} - h_{zz} e^{-i q} \left( 2 \right) \times \frac{1}{\epsilon_{\lambda,1} - \epsilon_{\lambda,2}}.
\end{align*}
