Microwave-enhanced catalytic wet peroxide oxidation of quinoline: the influence of pH and H\textsubscript{2}O\textsubscript{2} dosage and identification of reactive oxygen species†

Bo Zhang, *a Hong Youa and Fei Wanga

This article presents a comprehensive study about the influence of initial pH and H\textsubscript{2}O\textsubscript{2} dosage on quinoline mineralization efficiency (denoted by TOC abatement) by microwave-catalytic wet peroxide oxidation (MW-CWPO) with supported Cu–Ni bimetallic oxides as a catalyst and reactive oxygen identification on the basis of inhibition of quinoline mineralization using the specific radical scavengers. In an initial pH range from 2.0 to 8.0, this MW-CWPO was powerful, with the reaction at pH 7.0 obtaining the highest 81.12% TOC abatement under MW 500 W, H\textsubscript{2}O\textsubscript{2} 22.75 mmol L\textsuperscript{-1}, Cu/Ni-catalyst 4 g L\textsuperscript{-1}, and T 333 K. Five carboxylic acids, namely acetic acid, formic acid, succinic acid, oxalic acid, and glycolic acid, were quantified to elucidate the pH fall during mineralization under alkaline and neutral conditions. The experiments of reactive oxygen identification on the basis of inhibition of quinoline mineralization under the corresponding scavenger for ‘OH and O\textsubscript{2}’‘ exhibited ‘OH and O\textsubscript{2}’‘ immersed in supported bimetallic Cu/Ni oxides catalyzing MW-CWPO, and that ‘OH was a direct product and O\textsubscript{2}’‘ was a secondary oxidant produced from ‘OH-involved reactions. Based on the results of stability and metal leaching experiments, it could be concluded that supported Cu–Ni bimetallic oxides could be a proper catalyst.

1. Introduction

Heterogeneous catalytic wet peroxide oxidation (CWPO), a Fenton-like technology, has appeared as a potential technique for advanced oxidation processes (AOPs) and has aroused growing interest in wastewater purification owing to its natural advantages, such as wide-ranging pH, no metal sludge, and recyclable catalyst. Many solid catalysts containing monometallic transition metals like Fe\textsuperscript{2+} and Cu\textsuperscript{2+} have been confirmed to be effective in heterogeneous CWPO treatment of refractory wastewater. For example, Yan et al.,\textsuperscript{2} who examined phenol degradation using Fe\textsubscript{3}O\textsubscript{4}/MCM-41 as a heterogeneous CWPO catalyst in a fixed bed reactor, found that the conversion of TOC reached 72.5% under optimum conditions. Additionally, Huang et al.,\textsuperscript{3} reported the degradation of phenol using copper hydroxyl sulfates as a catalyst, and the phenol removal efficiency and COD removal were 99% and 97%, respectively, when the phenol concentration was 100 mg L\textsuperscript{-1} under the best conditions. However, iron species as a traditional catalyst show excellent catalytic activities,\textsuperscript{4} but the redox reaction between H\textsubscript{2}O\textsubscript{2} and iron-containing catalysts is somewhat unstable.\textsuperscript{5} Such drawbacks have induced great efforts to improve them. Copper species have received a lot of attention in the last 10 years because the redox reaction between H\textsubscript{2}O\textsubscript{2} and Cu species is more stable than that with iron.\textsuperscript{6} This characteristic promotes the application of copper-containing catalysts in water remediation.

Now, bimetallic catalytic materials have come to be a research hotspot in the field of heterogeneous CWPO over the last 10 years. In heterogeneous CWPO mineralization of phenol, Xu et al.,\textsuperscript{7} who tested heterogeneous CWPO to treat phenol over Cu/Fe-flokite used as a catalyst in a glass batch reactor, found that the removal of phenol using Cu/Fe-flokite was 1.37 times under the same reaction conditions than pure Cu-flokite, indicating that bimetallic catalytic materials may present better catalytic performance. Considering that Ni presents great catalytic performance in treatment of phenol and its derivatives,\textsuperscript{8} our previous work confirmed that supported bimetallic Cu/Ni oxides could be successfully applied in the heterogeneous MW-CWPO process to obtain high catalytic performance.\textsuperscript{9} The two-metal materials had enhanced catalytic activity owing to the synergistic effects of the two metals.

On the other hand, microwave-enhanced catalytic oxidation has gained wide interest from numerous scientific communities.
in the field of wastewater treatment because it has higher energy efficiency, shorter reaction time, and the transmission of charge supports the surface. Additionally, earlier research confirmed that the non-thermal effects of MW can promote the decomposition of H$_2$O$_2$ into hydroxyl radical (•OH). In heterogeneous CWPO mineralization of p-chlorophenol, Zhao et al. found that the TOC abatement was above 90% at 343 K within 15 minutes with MW irradiation, whereas it was merely 62.8% in an identical system without MW irradiations, demonstrating that under MW irradiation, the H$_2$O$_2$ utilization efficiency was enhanced. Analogous conclusions were attained during p-nitrophenol mineralization with CuO/Al$_2$O$_3$ catalyst. The utilization efficiency of H$_2$O$_2$ is an important parameter to assess H$_2$O$_2$-based systems because H$_2$O$_2$ utilization efficiency not only considerably impacts the operation cost in real-world applications, but also significantly affects the mineralization efficiency.

Furthermore, the effect of pH on mineralization performance is relatively different. Fajerwerg et al. found that phenol mineralization in heterogeneous CWPO decreased with increasing pH and the TOC abatement was 81.4% in 360 min with an initial pH of 2, and the mineralization efficiency was obviously impacted by the initial solution pH in a wide range of 2–7.0. Whether heterogeneous MW-CWPO could still retain high-pitched catalytic performance under neutral conditions is a key issue to be explored in detail. Additionally, most of the current studies on the mechanism involved in heterogeneous Fenton-like systems are based on the Haber–Weiss mechanism, mainly concentrating on yield of •OH. Nevertheless, few reports are available on the involvement of other radicals in heterogeneous Fenton-like systems.

The environmental persistence contaminant of quinoline, which has an N atom in the cyclic system, is very easy to be assembled in water environments. Besides, it is very harmful toward the health of humans and animals. It was chosen as the target pollutant to study the mineralization efficiency of supported bimetallic Cu/Ni oxides catalyzing MW-CWPO.

As part of our ongoing work in this field, this work presents the influence of initial pH and H$_2$O$_2$ dosage on quinoline mineralization to assess whether supported bimetallic Cu/Ni oxides catalyzing MW-CWPO could carry out the mineralization efficiently under neutral conditions, in addition to H$_2$O$_2$ utilization efficiency. Moreover, five carboxylic acids, namely acetic acid, formic acid, succinic acid, oxalic acid, and glycolic acid, were quantified to elucidate the pH fall during mineralization under alkaline and neutral conditions. Finally, specific radical scavengers were used to identify the oxygen radicals involved in supported bimetallic Cu/Ni oxides catalyzing MW-CWPO.

2. Experimental

2.1. Chemicals and reagents

All reagents utilized in this research were of analytical grade and were utilized without further purification. Quinoline was obtained from Sigma-Aldrich. The main characteristics of quinoline are presented in Table S1 of the ESL. Hydrogen peroxide (H$_2$O$_2$) (35%, w/w, stabilized), nitrobenzene (NB) and carbon tetrachloride (CT) were obtained from J&K Scientific. All solutions were prepared with Milli-Q water.

2.2. Preparation and characterization of catalyst

The supported Cu/Ni catalyst was prepared by the wet impregnation method with 50 mL of mixture (1.5 mol L$^{-1}$; Cu(NO$_3$)$_2$ and Ni(NO$_3$)$_2$; Cu(NO$_3$)$_2$ : Ni(NO$_3$)$_2$ = 5 : 1). The detailed synthetic methods are illustrated in Text S1. All the samples were kept in a desiccator for the subsequent experiments. The SEM images, EDX analysis, and XRD patterns of the as-synthesized catalyst are provided in Fig. S1. Furthermore, the elemental content of the as-prepared catalyst is provided in Table S2. The BET surface area, pore size, and pore volume of the as-synthesized catalyst were 136.64 m$^2$ g$^{-1}$, 0.34 cm$^3$ g$^{-1}$, and 10.11 nm, respectively.

2.3. Degradation experiments

Batch degradation experiments were carried out in a 500 mL glass flask equipped with a mechanical agitator, a reflux condenser and a thermocouple under MW irradiation. More information is offered in Text S2.

Samples were taken at set time intervals: some sample was promptly quantified for H$_2$O$_2$ concentration; Na$_2$SO$_3$ was introduced to the remainder to impede the ongoing redox reaction before TOC (Total Organic Carbon) measurement. In probing the oxygen radicals included in the heterogeneous MW-CWPO catalyzed by supported Cu/Ni bimetallic oxides, NB and carbon CT were utilized as scavengers for ‘OH and O$_2$•-, respectively, assessing the variation of the removal rate of 100 mg L$^{-1}$ quinoline with 22.75 mmol L$^{-1}$ H$_2$O$_2$, 4 g L$^{-1}$ Cu/Ni-catalyst, temperature of 333 K, and initial pH of 7.0 under MW (500 W) irradiation to identify relevant radicals.

3. Results and discussion

3.1. Influence of initial pH on quinoline mineralization in supported Cu/Ni bimetallic oxides catalyzing MW-CWPO

The solution pH value can substantially impact the MW-CWPO reaction. Thus, the influence of initial pH on quinoline
of organic acids, experiments were executed in buffer solutions of pH 6.8 and pH 7.6 including Na2HPO4·7H2O and NaH2PO4·H2O. From Fig. 1a, it was apparent that removal substantially decreased with a stable pH of 6.8 and 7.6. In Fenton reactions the optimum pH is usually 2.0–4.0. The benefit of supported Cu/Ni bimetallic oxides over soluble metal salts as a catalyst in CWPO lies in avoiding the shortcoming owing to metal ion precipitation. The reduced mineralization efficiency with buffers at pH 6.8 and 7.6 could be based on the fact that ‘OH has an oxidation-reduction potential of +1.5 V in basic media and +2.8 V in acidic media.38 In addition, it was noticed that the utilization of H2O2 with buffers of pH 6.8 and 7.6 was considerably inhibited, consequently diminishing the amount of reactive species for quinoline mineralization.

Fig. 1b displays the variation of H2O2 utilization efficiency with different initial pHs. As the pH rises from 2.0 to 7.0 in solution, the H2O2 utilization efficiency increased from 0.56 at pH 2.0 to 0.67 at pH 7.0 at 18 min. Higher H2O2 utilization efficiency indicates a lower required amount of H2O2 for the same mineralization efficiency. The values above 0.56 indicate that less TOC was removed than the theoretical value calculated from the amount of H2O2 in the reaction.29 The higher H2O2 utilization efficiency along with the highest TOC removal at initial pH of 7.0 in supported Cu/Ni bimetallic oxides catalyzing MW-CWPO would avoid the inherent disadvantages of homogeneous wet peroxide oxidation, including high H2O2 dosage and regulation of initial pH to be strongly acidic.39,40

3.2. Influence of H2O2 dosage on quinoline mineralization by supported Cu/Ni bimetallic oxides catalyzing MW-CWPO

The influence of H2O2 dosage was explored by altering the initial H2O2 concentration to 0.75 × ▲ H2O2, 1 × ▲ H2O2, 1.25 ×
\[ \Delta H_2O_2, 1.5 \times \Delta H_2O_2, \text{ and } 1.75 \times \Delta H_2O_2 \text{ mmol L}^{-1} \text{ theoretical } H_2O_2 \text{ dosage for mineralization of } 100 \text{ mg L}^{-1} \text{ quinoline.} \]

Fig. 2 Effect of H$_2$O$_2$ dosage on H$_2$O$_2$ utilization efficiency in MW-CWPO catalyzed by supported Cu/Ni bimetallic oxides. Except for the investigated H$_2$O$_2$ dosage, other parameters were fixed: 500 W, initial pH 7.0, 4 g L$^{-1}$ Cu/Ni-catalyst, 100 mg L$^{-1}$ quinoline, and T 333 K.

Fig. S57 shows that the TOC removal efficiency increased with H$_2$O$_2$ dosage over the range from 0.75 $\times$ $\Delta$ H$_2$O$_2$ to 1.75 $\times$ $\Delta$ H$_2$O$_2$ at 18 min. During the 18 min reaction time, the TOC abatement with 1.25 $\times$ $\Delta$ H$_2$O$_2$ was significantly higher than that at other H$_2$O$_2$ dosages; 1.5 $\times$ $\Delta$ H$_2$O$_2$, gave 81.12\%, indicating that an excessive dosage of H$_2$O$_2$ was not essential to attain satisfactory performance. Actually, with the exception of the reaction with 0.75 $\times$ $\Delta$ H$_2$O$_2$, there was some H$_2$O$_2$ left in the solution after 18 min, which were 0.72 mM, 0.99 mM, 2.01 mM, and 2.73 mM for the reactions with 1 $\times$ $\Delta$ H$_2$O$_2$, 1.25 $\times$ $\Delta$ H$_2$O$_2$, 1.5 $\times$ $\Delta$ H$_2$O$_2$, and 1.75 $\times$ $\Delta$ H$_2$O$_2$, respectively.

The H$_2$O$_2$ utilization efficiency in Fig. 2 demonstrates that the reaction with 1.25 $\times$ $\Delta$ H$_2$O$_2$ had the highest H$_2$O$_2$ utilization efficiency of 0.65. With increasing the dosage of H$_2$O$_2$ from 1.25 $\times$ $\Delta$ H$_2$O$_2$ to 1.75 $\times$ $\Delta$ H$_2$O$_2$, the utilization efficiency of H$_2$O$_2$ diminished from 0.65 to 0.40, which might be attributed to the scavenging of 'OH by excess H$_2$O$_2$.19,41

To acquire high efficiency of both TOC abatement and H$_2$O$_2$ utilization, the H$_2$O$_2$ dosage could be limited to the range of 1 $\times$ $\Delta$ H$_2$O$_2$ to 1.5 $\times$ $\Delta$ H$_2$O$_2$ for mineralization of 100 mg L$^{-1}$ quinoline. The high H$_2$O$_2$ utilization efficiency in this study poses a vital highlight of supported Cu/Ni bimetallic oxides catalyzing MW-CWPO, which is to reduce the H$_2$O$_2$ dosage and operation cost. Comparison of the H$_2$O$_2$ utilization efficiency for CWPO and MW-CWPO is displayed in Fig. 3.

The MW-CWPO systems had a significantly higher efficiency of H$_2$O$_2$ utilization than the CWPO systems, increased by more than 15\%. Furthermore, the MW-CWPO systems had better and quicker TOC removal efficiency. Further work was conducted to clarify the reason for the quite high utilization efficiency of H$_2$O$_2$ in the MW-CWPO systems.

3.3. Time course of generated carboxylic acids

In order to reveal the explanation for the pH fall during the supported Cu/Ni bimetallic oxides catalysis of the wet peroxide oxidation under microwave irradiation of quinoline, several short linear aliphatic carboxylic acids, namely acetic acid, formic acid, succinic acid, oxalic acid, and glycolic acid, were detected by HPLC after degradation with an initial pH of 7.0.

Fig. 4a displays the time-profile of carboxylic acids with 22.75 mmol L$^{-1}$ H$_2$O$_2$ (1.25 $\times$ $\Delta$ H$_2$O$_2$); acetic acid was the major constituent of the carboxylic acids, achieving the highest concentration of 73.15 mg L$^{-1}$ at 9 min in mineralization of 100 mg L$^{-1}$ quinoline. However, formic acid, oxalic acid, succinic acid, and glycolic acid were gathered to the highest values of 23.14 mg L$^{-1}$, 14.1 mg L$^{-1}$, 12.11 mg L$^{-1}$, and 7.11 mg L$^{-1}$ at 9 min, 12 min, 12 min, and 12 min, respectively. At the end of mineralization at 18 min, succinic acid and glycolic acid disappeared and only small amounts of acetic acid and oxalic acid existed, because most of them were degraded between 12 min and 18 min; acetic acid was the chief constituent of the residual carboxylic acids. The sum of TOC contributed by residual acetic acid, formic acid, and oxalic acid, was 16.35 mg L$^{-1}$, similar to the measured TOC value at 18 min of 17.16 $\pm$ 2 mg L$^{-1}$. As for the pH increase starting from 12 min presented in Table 1, it might be linked to the degradation of carboxylic acids for the reason that the carboxylic acids were substantially degraded during this period. When the H$_2$O$_2$ dosage was reduced to 18.20 mmol L$^{-1}$ H$_2$O$_2$ (1.00 $\times$ $\Delta$ H$_2$O$_2$), the time-profile of produced carboxylic acids was quite dissimilar to that with 22.75 mmol L$^{-1}$ H$_2$O$_2$ (1.25 $\times$ $\Delta$ H$_2$O$_2$). Fig. 4b shows the carboxylic acids produced with 18.20 mmol L$^{-1}$ H$_2$O$_2$ (1.00 $\times$ $\Delta$ H$_2$O$_2$). The succinic acid, formic acid, glycolic acid, and oxalic acid were unable to be decomposed while acetic acid was slowly but surely decomposed with 18.20 mmol L$^{-1}$ H$_2$O$_2$ (1.00 $\times$ $\Delta$ H$_2$O$_2$), which was probably caused by the inadequate production of reactive species like ‘OH owing to the lower H$_2$O$_2$ dosage. When decreasing the dosage of H$_2$O$_2$ in practical applications, an approach should be approved in which the effluent from supported Cu/Ni bimetallic oxides catalyzing MW-CWPO with high biodegradability is further clarified by successive biological treatment.

3.4. Identification of free radicals utilizing the chemical probe method

Although ‘OH has been widely acknowledged as the most active species in modified systems based on the Fenton system, the
production of other free radicals, for example, $\mathrm{O_2}^{\cdot-}$, had also been witnessed in some Fenton-like reactions.\(^{42}\)

Smith et al.\(^{43}\) confirmed that $\mathrm{O_2}^{\cdot-}$ is the main reductive species in the degradation of CT. Hence, it is quite probable that under specific situations, both redox reactions may promote the elimination of pollutants in the MW-CWPO systems at the same time. Hereafter, further research was carried out in this study to detect the generation of $\cdot\mathrm{OH}$ and $\mathrm{O_2}^{\cdot-}$ utilizing free radical probe tests. Based on the reaction with each of the free radicals potentially present in the MW-CWPO system, NB and CT were utilized as scavengers for $\cdot\mathrm{OH}$ and $\mathrm{O_2}^{\cdot-}$, respectively, because NB reacts with $\cdot\mathrm{OH}$ rapidly ($k_{\cdot\mathrm{OH}} = 3.9 \times 10^9 \text{ M}^{-1} \text{s}^{-1}$)\(^{44}\) and CT has high reactivity with $\mathrm{O_2}^{\cdot-}$ ($k_{\cdot\mathrm{OH}} < 2 \times 10^6 \text{ M}^{-1} \text{s}^{-1}$, $k_c = 1.6 \times 10^{10} \text{ M}^{-1} \text{s}^{-1}$).\(^{45}\)

Fig. 5a shows the impact of NB on quinoline degradation over the range of 0–50 mg L\(^{-1}\). The degradation rate of quinoline substantially declined with NB compared with that without NB. The results imply that $\cdot\mathrm{OH}$ was present in MW-CWPO, which caused quick quinoline removal. Furthermore, the quinoline removal in 18 min was 100% in the absence of NB. However, quinoline degradation was substantially impeded after NB addition and the impact of quinoline degradation was obviously dependent on NB dosage (Fig. 5a). The production of $\mathrm{O_2}^{\cdot-}$ in the MW-CWPO system, quantified by CT, is shown in Fig. 5b. Quinoline degradation was diminished to different degrees over the range of 0–50 mg L\(^{-1}\), but the impact degrees were less than that for NB. These results show that $\mathrm{O_2}^{\cdot-}$ was present in the MW-CWPO systems, participated in the quinoline degradation, and played a slight role in the quinoline degradation.

Based on the influence of NB and CT on quinoline degradation in supported bimetallic Cu/Ni oxides catalyzing catalytic wet peroxide oxidation under microwave irradiation, it could be concluded that $\cdot\mathrm{OH}$ and $\mathrm{O_2}^{\cdot-}$ were present in the MW-CWPO systems and the relative contribution of these two radicals followed the order: $\cdot\mathrm{OH} > \mathrm{O_2}^{\cdot-}$. Furthermore, quinoline degradation was completely impeded by scavenging $\cdot\mathrm{OH}$, implying that $\mathrm{O_2}^{\cdot-}$ was produced from reactions with the involvement of $\cdot\mathrm{OH}$.\(^{46}\) So, a simple mechanism of supported Cu/Ni bimetallic oxides catalyzing MW-assisted CWPO is proposed in Fig. 6.

3.5. Catalytic activity of Cu/Ni-catalyst in repeated runs

In exploring the stability and reusability of the Cu/Ni-catalyst in heterogeneous MW-CWPO, the catalytic reaction was conducted repeatedly six times with the Cu/Ni-catalyst under the standard reaction conditions. As seen in Fig. S6, the activity of the Cu/Ni-
During quinoline mineralization with an initial of pH 7.0, formic acid, acetic acid, oxalic acid, succinic acid, and glycolic acid were produced and instigated the fall of the solution pH to acidic conditions, favorable for high mineralization performance. In order to attain satisfactory mineralization efficiency and $\text{H}_2\text{O}_2$ utilization efficiency, the $\text{H}_2\text{O}_2$ dosage should be 1.25 times the theoretical value of $\text{H}_2\text{O}_2$ usage in mineralization of 100 mg L$^{-1}$ quinoline.

To identify the free radical species, CT and NB were introduced to the MW-CWPO system. Differences between the probes’ reactivity and the potential free radical species were perceived, indicating that $'\text{OH}$ was a direct product and $'\text{O}_2$ was a secondary oxidant produced from $'\text{OH}$-based reactions. The results of the stability and metal leaching experiments indicated that supported Cu-Ni bimetallic oxides could be applied as a proper catalyst.

**Fig. 6** A simple mechanism of supported Cu/Ni bimetallic oxides catalyzing MW-assisted CWPO.

**Table 2** Extent of metal leaching using reused Cu/Ni-catalyst

| Cycle number | Cu     | Ni     |
|--------------|--------|--------|
| 1st run      | 0.007  | 0.002  |
| 2nd run      | 0.004  | 0.0007 |
| 3rd run      | 0.001  | 0.0003 |
| 4th run      |        |        |
| 5th run      |        |        |
| 6th run      |        |        |

The extent of metal leaching using reused Cu/Ni-catalyst decreased gradually on the basis of TOC abatement and $\text{H}_2\text{O}_2$ utilization efficiency, probably owing to the leaching of iron from the catalyst surface as determined in the former section (Table 2). However, during the later third runs, TOC removal and $\text{H}_2\text{O}_2$ utilization efficiency were similar (Fig. S6†), implying that the catalyst may be stable.

Additionally, atomic absorption spectroscopy was utilized to measure whether there were any free Cu and Ni ions in the reaction solution after each reaction. The amount of metal leaching was analyzed after each experimental run (Table 2). As with the metal Cu and Ni leaching, quinoline mineralization efficiency and $\text{H}_2\text{O}_2$ utilization efficiency are reduced in acidic conditions, favorable for high mineralization performance. In order to attain satisfactory mineralization efficiency and $\text{H}_2\text{O}_2$ utilization efficiency, the $\text{H}_2\text{O}_2$ dosage should be 1.25 times the theoretical value of $\text{H}_2\text{O}_2$ usage in mineralization of 100 mg L$^{-1}$ quinoline.
