TRPC3 shapes the ER-mitochondria Ca\textsuperscript{2+} transfer characterizing tumour-promoting senescence

Valerio Farfariello\textsuperscript{1,2,11,12}, Dmitri V. Gordienko\textsuperscript{1,2,11}, Lina Mesilmany\textsuperscript{1,2,3,11}, Yasmine Touil\textsuperscript{4}, Emmanuelle Germain\textsuperscript{1,2}, Ingrid Fliniaux\textsuperscript{1,2}, Emilie Desruelles\textsuperscript{1,2}, Dimitra Gkika\textsuperscript{1,2,4}, Morad Roudbaraki\textsuperscript{1,2}, George Shapovalov\textsuperscript{1,2}, Lucile Noyer\textsuperscript{5}, Mathilde Lebas\textsuperscript{1,2}, Laurent Allart\textsuperscript{1,2}, Nathalie Zienthal-Gelus\textsuperscript{1,2}, Oksana Lamshanova\textsuperscript{6}, Franck Bonardi\textsuperscript{7}, Martin Figeac\textsuperscript{7}, William Laine\textsuperscript{4}, Jerome Kluza\textsuperscript{4}, Philippe Marchetti\textsuperscript{4}, Bruno Quesnel\textsuperscript{4}, Daniel Metzger\textsuperscript{8}, David Bernard\textsuperscript{9}, Jan B. Cellular senescence is implicated in a great number of diseases including cancer. Although alterations in mitochondrial metabolism were reported as senescence drivers, the underlying mechanisms remain elusive. We report the mechanism altering mitochondrial function and OXPHOS in stress-induced senescent fibroblasts. We demonstrate that TRPC3 protein, acting as a controller of mitochondrial Ca\textsuperscript{2+} load via negative regulation of IP\textsubscript{3} receptor-mediated Ca\textsuperscript{2+} release, is down regulated in senescence regardless of the type of senescence inducer. This remodelling promotes cytosolic/mitochondrial Ca\textsuperscript{2+} oscillations and elevates mitochondrial Ca\textsuperscript{2+} load, mitochondrial oxygen consumption rate and oxidative phosphorylation. Re-expression of TRPC3 in senescent cells diminishes mitochondrial Ca\textsuperscript{2+} load and promotes escape from OIS-induced senescence. Cellular senescence evoked by TRPC3 downregulation in stromal cells displays a proinflammatory and tumour-promoting secretome that encourages cancer epithelial cell proliferation and tumour growth in vivo. Altogether, our results unravel the mechanism contributing to pro-tumour behaviour of senescent cells.
It is now well established that various cell-stressing factors, such as DNA-damaging radiations, oxidative stress or oncogene activation, are able to initiate an alternative cellular response to DNA damage that engages the p53 and pRB tumour suppressor pathways culminating in the induction of premature senescence\textsuperscript{1–3}. Senescent cells are depicted by specific characteristics such as morphological modifications, cell cycle arrest, apoptosis resistance and altered gene expression. Despite the irreversible loss of their proliferative ability, senescent cells remain metabolically active and secrete several soluble factors,
referred to as senescence-associated secretory phenotype (SASP)4–6, which includes secreted proteins like metalloproteases, inflammatory cytokines and growth factors.

Chemotherapeutic agents have also been shown to induce so-called chemotherapy-induced senescence (CIS)1–3. The induction of CIS in the tumour microenvironment alters the cross-talk between tumour and stromal cells via development of the SASP, thus supporting tumour relapse and the resistance to further antineoplastic therapies. Indeed, stromal cell CIS is able to boost neoplastic epithelial cell proliferation by paracrine mechanisms. This involves molecules such as FGF, HGF, amphiregulin and WNT16B recently identified as components of the SASP in the tumour microenvironment and capable of promoting cell survival/disease progression and attenuating the effects of cytotoxic chemotherapy7–10. It is therefore vital to identify molecular actors regulating senescence in stromal cells and the underlying molecular mechanisms.

In recent years, emerging evidence indicate that the mitochondrial activity is coupled to cellular senescence. Mitochondrial dysfunction has been described to induce a specific subset of senescence called "mitochondrial dysfunction-associated senescence (MiDAS)"11) and more recently, NAD+ metabolism has been related to the acquisition of a proinflammatory senescence-associated secretome12. In addition, mitochondrial reactive oxygen species (ROS) production is known to induce/ stabilise the DNA damage response (DDR), leading to a permanent growth arrest13. It is now clear that mitochondrial metabolism is tightly coupled to cellular Ca2+ homeostasis. Indeed, mitochondria both encode and decode Ca2+ signals which in turn have a direct impact on oxidative phosphorylation (OXPHOS) and ATP production. Indeed, mitochondrial Ca2+ transients have been reported to increase mitochondrial dehydrogenase (DHase) activity that in turn enhances ATP synthesis. Taking into account that three key DHases of the tricarboxylic acid (TCA) cycle are Ca2+ dependent, it was suggested that mitochondrial Ca2+ regulates the NADH/NAD+ ratio and, hence, controls ATP synthesis14–16.

Nevertheless, the mechanisms underlying mitochondrial Ca2+ homeostasis alteration in senescent cells are not yet well understood. Normal mitochondrial Ca2+ homeostasis relies on functional endoplasmic reticulum (ER)–mitochondrial Ca2+ transfer due to constitutive activity of inositol 1,4,5-trisphosphate receptors (IP3Rs)17. We and others have recently shown that IP3R-mediated Ca2+ release from the ER and subsequent Ca2+ accumulation in mitochondria lead to cellular senescence in normal human cells18–21. It is important to note that a great number of partner proteins not only regulate (either directly or via multiple signalling pathways) the IP3R activity, but also determine the molecular targets of IP3R-mediated Ca2+ release22. Among these, a number of oncogenes and tumour suppressor proteins have been identified23–25 shedding light on the Ca2+ dependence of the cancer hallmarks. Whether alteration of the IP3R activity in senescence is mediated by partner protein(s), however, remains unknown.

Here we show how cytosolic and mitochondrial Ca2+ signatures are altered in senescent cells and whether these alterations affect the SASP composition and tumour progression. Our results provide original insights into the determinants of Ca2+-dependence in pro-tumour senescence.

Results

Senescent cells display TRPC3 downregulation and altered calcium homeostasis. One of the most widespread families of Ca2+-permeable channels known to affect IP3R activity and to be recruited during capacitative Ca2+ entry are transient receptor potential (TRP) channels22,26.

In order to assess possible changes in the expression of Ca2+-permeable channels in senescence, we used several experimental models: (1) human prostate fibroblasts (HPFfs) and prostate cancer-associated fibroblasts (CAFs) treated with docetaxel (Docet)—a microtubule poison commonly used in prostate cancer therapy27,28 and known to induce senescence in several cell types3,9; (2) HPFs treated with hydrogen peroxide, H2O2,29,30 and (3) MRC-5 fibroblasts in which senescence was induced by oncogenic RAS (hRASG12V)31. The induction of senescence was confirmed by SA-β-galactosidase staining (Supplementary Fig. 1a–d)32.

Knowing that, on the one hand, Ca2+-permeable channels are involved in the establishment of senescence18 and, on the other hand, a number of tumours are considered as oncocannelopathies33, we therefore performed a real-time qPCR screening for the members of TRP, IP3Rs, ORAI channel families and the accessory molecules STIM and some of the main Ca2+-permeable mitochondrial channels. As shown by the heat map in Fig. 1a, the senescent phenotype was associated with alterations in the expression of several genes, among which Trpc3 was the only gene found to be consistently and significantly downregulated in all models of senescence (Supplementary Table 2). This was also confirmed at the protein level (Fig. 1B–E). Moreover, the decline of Trpc3 expression was found to occur at an early stage of the senescent phenotype establishment (Supplementary Fig. 1e–h). Noteworthy, the expression of the genes encoding diacylglycerol (DAG)-sensitive TRPC3 homologues, Trpc6 and Trpc7 (the latter was not expressed) was not affected.

We analysed the expression of TRPC3 in human prostate cancer tissues using published microarray datasets obtained from chemo/radiotherapy-treated patients. We found that TRPC3, reported to be predominantly expressed in the prostate stroma34, was downregulated in tumours from patients undergoing anticancer treatments (Supplementary Fig. 1j–k) (ONCOMINE: Datasets “Grasso Prostate” and “Tamura Prostate”). This was also true for other malignancies, such as breast cancer (Supplementary Fig. 1l). TRPC3 downregulation in senescent cells was also confirmed by the analysis of public datasets reporting gene expression changes caused by treatments with pro-senescent compounds or RAS expression, as depicted in Supplementary Fig. 11.
Moreover, in the tumours expressing low levels of TRPC3, the gene set enrichment analysis (GSEA) conducted on the data from the gene expression omnibus (GEO) dataset GSE35988 from prostate cancer tissues showed a strong enrichment of the genes upregulated in senescence (Human Cellular Senescence Gene Database, HCSGD\textsuperscript{35}, Supplementary Fig. 1m).

To decipher the Ca\textsuperscript{2+} signalling events characterising senescence, basal cytosolic Ca\textsuperscript{2+} levels, the magnitudes of Ca\textsuperscript{2+} release and Ca\textsuperscript{2+} entry were measured in two senescence models, CIS and oncogene-induced senescence (OIS), utilising ratiometric fluorescence wide-field Ca\textsuperscript{2+} imaging with Fura-2/AM (Fig. 1f–i). Our results show a slight but significant increase in basal cytosolic Ca\textsuperscript{2+} concentration ([Ca\textsuperscript{2+}]\textsubscript{c}) in senescent cells. Application of histamine (an endogenous activator of the G-protein–phospholipase C–IP\textsubscript{3}–IP\textsubscript{3}R-mediated Ca\textsuperscript{2+} release signalling pathway\textsuperscript{36}) to cells bathed in a Ca\textsuperscript{2+}-free solution revealed that Ca\textsuperscript{2+} release from the ER is dramatically increased in senescent cells. This was associated with a significant increase in capacitative Ca\textsuperscript{2+} entry (SOCE) following Ca\textsuperscript{2+}...
readmission only in cells with CIS (Fig. 1f and g). However, in OIS, SOCE was found to be decreased (Fig. 1h and i). Moreover, analysis of single cell responses (examples are shown in Supplementary Fig. 2a, b) revealed that senescent cells are prone to cytotoxic Ca^{2+} oscillations. Taken together, these results indicate that IP_{3}R-mediated Ca^{2+} release from the ER is increased in senescence, thus confirming results obtained previously in other models.\(^14\)

**TRPC3 regulates senescence.** The above results brought up the question about roles of TRPC3 protein in the acquisition of the senescent phenotype. To address it, we downregulated Trpc3 expression in HPrFs or MRC5 using siRNA or doxycycline-inducible shRNAs (Supplementary Fig. 2C, D). Trpc3 knockdown (KD) resulted in senescence induction, reported by proliferation arrest (depicted by the cumulative population doubling, crystal violet and EdU staining; Fig. 2a, b), increased cell size and augmented SA-β-gal activity (Fig. 2c and Supplementary 2e), the activation of the P53/P16 pathways (Fig. 2d) and the formation of heterochromatin foci (Fig. 2e). Of note, as shown by Annexin V/7-AAD staining and flow cytometry analysis (Supplementary Fig. 2f), TRPC3 KD does not induce cell death, what otherwise would compromise the assessment of proliferation rate. Furthermore, downregulation of the TRPC3 homologue, TRPC6, failed to induce senescence (Supplementary Fig. 2g, h), thus highlighting the specific role of TRPC3. Conversely, overexpression of TRPC3 by means of a doxycycline-inducible system (Supplementary Fig. 2i) promoted escape from OIS, as reported by colony formation assays and SA-β-gal staining (Fig. 2f) showing proliferation rescue after 3 weeks in culture. Escape from senescence was also confirmed by WB analysis of proliferation (Cyclin D1/PCNA1) and senescence (p16 expression) markers, respectively (Fig. 2g).

Altogether, these results indicate that TRPC3 is involved in the establishment of the senescent phenotype.

**TRPC3 constitutively inhibits IP_{3}R-mediated Ca^{2+} release.** Alteration of the ER Ca^{2+} homoeostasis observed in senescent cells (Fig. 1f–i and Supplementary Fig. 2a, b), on the one hand, and the induction of senescence by Trpc3 KD, on the other hand, suggest that TRPC3 may be involved in the regulation of the ER Ca^{2+}-release mechanisms.

To check whether TRPC3 downregulation affects ER Ca^{2+} homoeostasis, we used an experimental strategy similar to the one shown in Fig.1f–i, but on shCTRL or shTRPC3-expressing MRC5. Results were similar to those obtained in senescent cells: the shTRPC3-expressing cells showed elevated basal cytoplasmic Ca^{2+}, increased histamine-induced Ca^{2+} release from the ER and increased capacitative Ca^{2+} entry (Fig. 3a). The latter results strongly suggest that TRPC3 does not contribute directly to the store-operated Ca^{2+} entry (SOCE), at least in this model.

We also observed that TRPC3-KD cells are prone to spontaneous cytosolic Ca^{2+} oscillations (Supplementary Fig. 3a, b).

Considering that TRPC3 downregulation facilitates cytosolic Ca^{2+} events, we hypothesised that its function is to regulate ER Ca^{2+}-release channels rather than to act as an ER Ca^{2+}-release channel.

It was previously reported that TRPC3 channel activity can be tuned by its interaction with IP_{3}R5,38 that occurs between the calmodulin/IP_{3} receptor-binding (CIRB) region on the C-terminal fragment of TRPC3 and the N-terminal fragment of the IP_{3}R5,39. Using absolute qPCR quantification, we found that prostate fibroblasts express all three IP_{3}R isoforms, of which type 3 accounts for almost 80% (Supplementary Fig. 3c). Western blot analysis performed on subcellular fractions showed that TRPC3 is also expressed in the ER membrane (Supplementary Fig. 3d). Moreover, co-immunoprecipitation and western blot analysis revealed that TRPC3 interacts with IP_{3} receptor type 3 (IP_{3}R3) in fibroblasts (Supplementary Fig. 3e).

To test whether TRPC3 is involved in the regulation of the IP_{3}R-mediated Ca^{2+} release from the ER, we performed confocal cytosolic Ca^{2+} imaging in cells expressing shCTRL or shTRPC3 after stimulation with IP_{3}-AM. We found that downregulation of TRPC3 augmented IP_{3}-induced Ca^{2+} oscillations (Fig. 3b). These results confirm our hypothesis that IP_{3}R activity is regulated by TRPC3 upon establishment of the senescent phenotype.

For further verification, we conducted confocal Ca^{2+} imaging on prostate fibroblasts stably expressing the ER-targeted ratiometric Ca^{2+} indicator GEM-CEPIA1 (Supplementary Fig. 4a)\(^40\). To assess the rate of the ER Ca^{2+} release directly, fibroblasts bathed in an intracellular-like media with Ca^{2+} clamped at 50 nM (note that Mg^{2+} and ATP were omitted to inhibit SERCA-mediated Ca^{2+} re-uptake) were briefly exposed to 40 μM digitonin (to permeabilize the plasma membrane) during x–y time series imaging (Supplementary Fig. 4b). This revealed that the mean rate of Ca^{2+} release was augmented by TRPC3 knockdown, while TRPC3 overexpression significantly reduced it (Fig. 3c, d). To probe for a possible contribution of IP_{3}Rs to this release we tested the effect of Xestospongin C (XeC, 5 μM), a well-known inhibitor of IP_{3}R41,42. As shown in Fig. 3e and f, inhibition of IP_{3}Rs reduces the permeabilization-unmasked Ca^{2+} release from the ER by about 80%. This indicates that even without exogenous IP_{3}R stimulation, the observed release is mediated mainly via IP_{3}Rs and thus depends on TRPC3 expression levels.

Fig. 3 TRPC3 inhibits ER Ca\textsuperscript{2+} release. a Cytosolic Ca\textsuperscript{2+} imaging (Fura-2) performed on HPrFs 10 days after shRNA induction. Left: averaged time courses (mean ± SEM of fluorescence ratio with excitation wavelengths 340/380 nm. Right: panels comparing the mean values of (1) basal cytosolic Ca\textsuperscript{2+} levels, (2) peak amplitudes of the Histamine (100 μM)-induced ER Ca\textsuperscript{2+} release and (3) peak amplitudes of SOCE, respectively (n\textsubscript{shCTL} = 25, n\textsubscript{shTRPC3} = 26). ***P < 0.001 (Student’s t test, two-sided). b Representative traces (left) of IP\textsubscript{3}-AM (250 nM)-induced [Ca\textsuperscript{2+}] oscillations reported by confocal time-series imaging (at 5 Hz) of Fluo-4 fluorescence in fibroblasts 5 days after shRNA induction: shCTL and shTRPC3, respectively. The bar diagram plot (right) compares corresponding mean signal temporal densities (n\textsubscript{shCTL} = 25, n\textsubscript{shTRPC3} = 26). ***P < 0.001 (Student’s t test, two-sided). See also Supplementary Figs. 2 and 3.

To analyse the dependence of the release rate on the IP\textsubscript{3} concentration ([IP\textsubscript{3}]) following cell membrane permeabilization with digitonin, the cells were superfused with a solution supplemented with XeC at different concentrations ranging from: 0 to 10,000 nM (Supplementary Fig. 4c). The kinetics of Ca\textsuperscript{2+} release from the ER observed at different [IP\textsubscript{3}] was then compared between MRC5 cells with downregulated (Fig. 4a) or overexpressed TRPC3 (Fig. 4b). This revealed that TRPC3: (1) exerts an inhibitory effect on the Ca\textsuperscript{2+} release at [IP\textsubscript{3}] = 0–1000 nM (Fig. 4c, d) and (2) reduces the sensitivity of IP\textsubscript{3}Rs to IP\textsubscript{3} at [IP\textsubscript{3}] < 100 nM (Fig. 4e).

To confirm these findings, we assessed the regulation of IP\textsubscript{3}R activity by TRPC3 at single channel level using electrical recordings from organelle membrane-derived patches\textsuperscript{43}. This approach utilises the incorporation of extracted intracellular membrane fractions into giant uni-lamellar vesicles and allows characterising the activity of the channels from the fragments of cellular organelles in endogenous protein environment and their regulation by partner proteins using standard patch-clamp recording. We found that the open probability of the IP\textsubscript{3}R channels was markedly reduced in giant uni-lamellar vesicles (GUVs) obtained from TRPC3-overexpressing membranes (Fig. 4f). These results, together with our previous findings (see Supplementary Fig. 3d), suggest that TRPC3 inhibits the IP\textsubscript{3}Rs from within the ER.

TRPC3 exerts its effect on IP\textsubscript{3}R via a direct interaction rather than via its channel activity. It is well known that IP\textsubscript{3}R channel activity is sensitive to cytosolic and intraluminal Ca\textsuperscript{2+} concentrations, and is regulated by several partner proteins\textsuperscript{22}. To determine whether inhibition of the IP\textsubscript{3}R-mediated Ca\textsuperscript{2+} release by TRPC3 results from a Ca\textsuperscript{2+}–mediated interplay between these two channels or is governed by protein–protein interaction, we transduced MRC5 fibroblasts with the TRPC3 C1RB domain mutant (MKR/AAA) which disrupts the interaction between the two proteins\textsuperscript{44}. The expression of this mutant, in contrast to the expression of the wild-type TRPC3, had virtually no effect on the IP\textsubscript{3}-induced Ca\textsuperscript{2+}–release (Fig. 4g and Supplementary Fig. 4d). In addition, the inhibitory effect of TRPC3 overexpression on the IP\textsubscript{3}-mediated Ca\textsuperscript{2+} release was only slightly reduced when the pore channel mutants, E630Q (“Ca\textsuperscript{2+} permeation-deficient”) or E630K (“pore-dead”)\textsuperscript{45} were overexpressed instead of wild-type TRPC3 (Fig. 4h and Supplementary Fig. 4e), indicating that TRPC3 exerts its inhibitory effects via direct interaction with IP\textsubscript{3}R.

Relief of the TRPC3-mediated inhibition of IP\textsubscript{3}Rs promotes ER–mitochondria Ca\textsuperscript{2+} transfer and increased OXPHOS facilitating senescence. Bearing in mind the inhibition of IP\textsubscript{3}R-mediated Ca\textsuperscript{2+} release by TRPC3, we hypothesised that the augmented ER Ca\textsuperscript{2+} release caused by TRPC3 downregulation in senescence may lead to enhanced mitochondrial Ca\textsuperscript{2+} uptake, which was previously implicated in senescence induction\textsuperscript{18}.

To probe mitochondrial Ca\textsuperscript{2+}, we transduced MRC5 fibroblasts with the mitochondria-targeted ratiometric Ca\textsuperscript{2+} sensor GEM-GECO1mito\textsuperscript{46} (Supplementary Fig. 5a, b) and assessed the effect of TRPC3 downregulation on the mitochondrial Ca\textsuperscript{2+} concentration ([Ca\textsuperscript{2+}]\textsubscript{mito}). Comparison of the mean values of GEM-GECO1mito fluorescence ratio at the two wavelength bands in a number of x–y confocal images revealed that TRPC3 knockdown resulted in significant elevation of [Ca\textsuperscript{2+}]\textsubscript{mito} (Fig. 5a). Conversely, the elevation of [Ca\textsuperscript{2+}]\textsubscript{mito} observed in shCTL, was prevented by the rescue of TRPC3 expression (Fig. 5b) to the same extent as by MUC silencing (Supplementary Fig. 5c, d). Of note, TRPC3 overexpression decreased the basal [Ca\textsuperscript{2+}]\textsubscript{mito} of non-senescent cells, suggesting that TRPC3 also regulates the ER–mitochondrial Ca\textsuperscript{2+} transfer in normal physiological conditions. To elucidate whether the difference in the apparent steady-state [Ca\textsuperscript{2+}]\textsubscript{mito} is related to an alteration of the mitochondrial Ca\textsuperscript{2+} uptake we have conducted x–y time series confocal imaging. This revealed that TRPC3 knockdown promotes mitochondrial Ca\textsuperscript{2+} oscillations (Fig. 6a, b) leading to a dramatic augmentation of the mean signal temporal density (Fig. 6c). The latter explains the elevated apparent steady-state [Ca\textsuperscript{2+}]\textsubscript{mito} observed in Fig. 5a. Dynamic confocal imaging of TMRE fluorescence revealed that TRPC3 knockdown promotes spontaneous transient depolarisation of the mitochondrial membrane potential, ΔΨ\textsubscript{mito} (Fig. 6d–f), known as mitochondrial flickers\textsuperscript{47}.

Taking into account that Ca\textsuperscript{2+} is an important regulator of mitochondrial function\textsuperscript{14–16} which is altered in senescent cells\textsuperscript{11,48,49}, we assessed whether TRPC3 downregulation affects mitochondrial metabolism.

Assessment of the total NAD\textsuperscript{+}/NADH and ADP/ATP ratios demonstrated that TRPC3 knockdown effectively alters cellular metabolism (Supplementary Fig. 6a, b), leading to significant accumulation of NAD\textsuperscript{+} and elevated total ADP/ATP ratio in siTRPC3-expressing cells. However, in the mitochondrial compartment, TRPC3 downregulation increased ATP levels (Fig. 7a).

We therefore investigated further these alterations by measuring mitochondrial respiration. As expected, TRPC3 downregulation significantly increased mitochondrial oxygen consumption rate (OCR) (Fig. 7b, c). Moreover oligomycin-sensitive respiration, known as ATP turnover, was found to be increased in TRPC3-KD cells relative to siCTL (Fig. 7d), thus, suggesting elevated ATP production. Of note, the enhancement of mitochondrial metabolism observed in TRPC3-KD cells was fully reversed by IP3R3 downregulation (Fig. 7c, d). Conversely,
the increased basal OCR and proton leak observed in OIS was prevented by rescue of TRPC3 expression (Supplementary Fig. 7a–e), what reflects the importance of TRPC3 in the regulation of mitochondrial metabolism in senescence. However, the increase of maximal OCR observed in OIS was not abolished by TRPC3 downregulation, what, likely, reflects differences in regulation of FCCP-stimulated and basal respiration.\(^50\). Monitoring of ROS production (with MitoSox Red) by mitochondria visualised with MitoTracker Deep Red, showed that TRPC3 kD leads to augmented genesis of ROS, which was notably prevented by the concurrent suppression of IP3R3 (Fig. 7e and Supplementary Fig. 6d).
Our flow cytometry analyses revealed that the percentage of senescent cells observed after TRPC3 knockdown was reduced following: (1) inhibition of Ca\(^{2+}\) transfer to mitochondria by Ru360, (2) IP\(_3\)R3 knockdown or (3) mitochondrial ROS scavenging by MitoTempo (Supplementary Fig. 6h). Altogether, these observations unravel a chain of signalling events caused by TRPC3 downregulation and leading to enhanced OXPHOS and elevated mitochondrial ROS production (reported to maintain senescence\(^1\)), providing an additional evidence for the role of TRPC3 in modulation of the ER–mitochondrial Ca\(^{2+}\) transfer and mitochondrial metabolism observed in senescence.

TRPC3 downregulation is characterised by a tumour-promoting SASP. The SASP secretion supports tumour progression, since it promotes cancer cell proliferation, resistance to chemotherapy and a pro-inflammatory microenvironment\(^4\). In this context, mitochondrial metabolism seems to play a central role\(^2\). However, mitochondrial dysfunction has also been associated with another secretory phenotype, lacking the IL-1-dependent inflammatory arm and altering the differentiation of preadipocytes and keratinocytes\(^1\). To discriminate between these two distinct phenotypes, we analysed the SASP secreted upon TRPC3 downregulation. Antibody arrays covering a large spectrum of cytokines, chemokines and growth factors, showed that TRPC3 downregulation is associated with a pro-inflammatory and pro-tumour SASP, notably including IL-8, ENA-78, GRO-alpha and other soluble factors associated with tumour progression and aggressiveness (Fig. 8a and Supplementary Fig. 8a).

Because TRPC3 KD cells show an important secretion of SASP per se, we next aimed to check if TRPC3 overexpression in senescent cells would modify their SASP expression. To this aim, we rescued TRPC3 in OIS and checked, by qRT-PCR, the expression of some of the main SASP components. Our data confirm further the role of TRPC3 in the regulation of the senescent cells secretome, since its overexpression led to a drastic reduction of SASP (Supplementary Fig. 8b). To test whether this SASP exerted any pro-tumour effect in vitro, we incubated PC3 and DU145 prostate epithelial cancer cells with a medium conditioned with prostate cancer associated fibroblasts (CAFs) expressing either shTRPC3 or shCTL. Comparison of the effect of the conditioned medium (CM) from the two groups of CAFs on the proliferation rate of the epithelial cells revealed only modest effect of the shTRPC3: ~35% increase in the epithelial cell proliferation rate (Fig. 8b). Of note, the effects of conditioned medium from OIS cells on prostate cancer cell proliferation were measured at different concentration of IP\(_3\) (as depicted above plots in corresponding colours) 5 days after shRNA induction (\(n = 76, 80, 101, 117\) and 80, respectively, for \([\text{IP}_3] = 0, 10, 100, 1000\) and 10,000 nM) or 3 days after TRPC3 overexpression (\(n = 52, 113, 51, 104\), and 59, respectively for \([\text{IP}_3] = 0, 10, 100, 1000,\) and 10,000 nM) (Fig. 8c).

To verify whether modification of the SASP caused by TRPC3 downregulation could contribute to the acquisition of a chemotherapy-resistant phenotype, we assessed the effect of SASP secreted by CAFs on prostate cancer cells. To this end, we cultured CAFs expressing either shCTL or shTRPC3 for 24 h and then exposed PC3 and DU145 prostate cancer cells to the corresponding conditioned medium. Prostate cancer cells treated with non-conditioned medium were used as control. Following a 24 h incubation, the cells were transferred to media containing either docetaxel or vehicle (DMSO) only and cultured for an extra 48 h. Cell viability was then measured for all six conditions. The chemotherapeutic-resistance was expressed as a ratio of the cell viability observed after treatment with docetaxel to that observed with vehicle only (Fig. 8d). This approach revealed that in both prostate cancer cell models tested, the resistance to docetaxel was significantly stronger following incubation with conditioned medium derived from the CAFs expressing shTRPC3: about 25% increase in cell viability relative to that observed with the medium derived from shCTL-expressing CAFs. Of note, the incubation in the conditioned medium derived from shCTL-expressing CAFs, per se increased the resistance to DOX, but only in PC3 cells. Thus, our results reveal that TRPC3 suppression in both normal and cancer-associated fibroblasts modify the behaviour of epithelial cancer cells. To assess further our hypothesis that TRPC3 suppression in stromal cells favours a senescent pro-tumour microenvironment, we have conducted in vivo experiments. In these experiments, HPrFs carrying doxycycline-inducible shTRPC3 or shCTL were pre-treated with doxycycline for 7 days to induce senescence. These cells were then mixed with PC3-Luc cells in proportion 1:2 and injected subcutaneously into immunodeficient mice. The animals were then imaged once a week during 6 weeks. The results of the bioluminescence imaging and tumour size measurements revealed that TRPC3 downregulation in prostate stromal cells accelerates growth of the newly formed subcutaneous prostate tumours (Fig. 8e–g). This suggests that stromal cells senescence caused by TRPC3 downregulation facilitates cancer progression mainly via the production of a pro-inflammatory and pro-tumour SASP.

Discussion
Our study uncovers a molecular mechanism underlying mitochondrial dysfunction that contributes to pro-tumour effects of senescence. In particular, we demonstrated that, in proliferating cells, TRPC3 inhibits the IP\(_3\)R-mediated Ca\(^{2+}\) release thus limiting the ER–mitochondria Ca\(^{2+}\) transfer, while the development of senescent phenotype is associated with TRPC3 downregulation. This, in turn, results in augmented mitochondrial Ca\(^{2+}\) uptake/load, mitochondrial depolarisation, elevated ROS production and mitochondrial metabolism alteration.

This inhibition of IP$_3$Rs by TRPC3 appeared to be unrelated to its potential activity as Ca$^{2+}$-permeable channel. Indeed, on the one hand, downregulation of TRPC3 was associated with significant increase in the ER Ca$^{2+}$ release, while its overexpression had the opposite effect (Fig. 3c, d). The observed effects cannot be attributed to a potential variability in cytosolic Ca$^{2+}$ concentration ([Ca$^{2+}$]) or SERCA activity, since the measurements were performed on permeabilized cells superfused with Mg$^{2+}$/ATP-free solution with [Ca$^{2+}$] clamped at 50 nM. On the other hand, the observed increase of the mitochondrial Ca$^{2+}$ uptake/load upon TRPC3 downregulation (Figs. 5 and 6) rules out that TRPC3-mediated mitochondrial Ca$^{2+}$-uptake is the main mechanism controlling ER Ca$^{2+}$ homeostasis. All the above suggest that the most likely mechanism, which determines the dependence of the ER Ca$^{2+}$ release on TRPC3 bioavailability, is the regulation of other Ca$^{2+}$-permeable channel(s) in the ER membrane by TRPC3. IP$_3$R is commonly recognised as the major conduit contributing to the ER–mitochondria Ca$^{2+}$ transfer$^{31}$. inhibition of the ER Ca$^{2+}$ release by the IP$_3$R inhibitor XeC$_{32}$ indicates that IP$_3$Rs are responsible for about 80% of the Ca$^{2+}$ release from the ER of prostate stromal cells (Fig. 3e, f). Our co-immunoprecipitation experiments confirmed the interaction between TRPC3 and IP$_3$R3 proteins (Supplementary Fig. 3e), while the dynamic confocal imaging of the [Ca$^{2+}$]$_{ER}$ changes in permeabilized stromal cells (Fig. 4a-f) and patch-clamp recording of the IP$_3$R single channel activity (Fig. 4g) provided the most direct evidence of IP$_3$R activity inhibition by the TRPC3 protein. The fact that this inhibition is caused by the TRPC3–IP$_3$R interaction rather than the TRPC3 channel activity was confirmed further with TRPC3 mutants (Fig. 4h, i).

The ER–mitochondria Ca$^{2+}$ transfer is essential for cell metabolism, since mitochondrial Ca$^{2+}$ uptake is crucial for the regulation of the oxidative phosphorylation and ATP production. On the one hand, in many cell types, reduction of the constitutive IP$_3$R-mediated Ca$^{2+}$ transfer to mitochondria results in autophagy that opposes a bioenergetic crisis and promotes cell survival$^{17,52}$. However, in cancer cells, the induction of autophagy is not sufficient for cell survival, since necrotic cell death prevails due to mitochondrial dysfunction$^{34}$. In this context, the authors showed that suppression of about 80% of the ER-Ca$^{2+}$ release events (and the consequent loss of Ca$^{2+}$ transfer to the mitochondria) following xestospongin application compromised cell bioenergetics and evoked either pro-survival macroautophagy in normal cells, or cell death in transformed or tumour cells. However, the extent of mitochondrial Ca$^{2+}$ uptake alteration in these cells was not reported$^{17,53}$. On the other hand, a sustained increase of mitochondrial Ca$^{2+}$ concentration induces apoptosis, since mitochondrial Ca$^{2+}$ overload leads to mitochondrial swelling and, hence, to perturbation/rupture of the outer mitochondrial membrane, release of mitochondrial apoptotic factors into the cytosol and activation of the caspase cascade$^{34}$.

Another possible consequence of mitochondrial dysfunction is the induction of senescence. Indeed, several papers associate ROS production with the induction and stabilisation of senescence, as well as with OXPHOS$^{35}$. Our results confirm further the role of mitochondrial homeoeostasis and bioenergetics in senescence, since TRPC3 downregulation leads to increased OXPHOS (reported by augmented NAD+/NADH and ADP/ATP levels) and augmented mitochondrial ROS production.

The spatio-temporal pattern of Ca$^{2+}$ signalling is an important determinant of cell fate$^{36}$. One of the major findings of our paper is that the relief of the TRPC3-mediated IP$_3$R inhibition caused by TRPC3 downregulation facilitates [Ca$^{2+}$] oscillations in the cytosol and mitochondria rather than sustained elevation of [Ca$^{2+}$]$_{mito}$. This specific oscillatory Ca$^{2+}$ signalling in prostate stromal cells seems then to be a crucial point for the choice of the induction of senescence as an alternative to autophagy or apoptosis. Although senescent cells are more prone to Ca$^{2+}$ oscillations than their proliferative counterpart, we observed that SOCE amplitude in senescence may vary. This is not surprising, since it is generally recognised that different Ca$^{2+}$ signatures can lead to a same cell fate$^{32}$. However, understanding and deciphering these differences is a challenge that deserves to be explored to better characterise the role of Ca$^{2+}$ signalling in senescence.

Senescence in the microenvironment exerts a well-documented pro-tumour effect. Indeed, SASP content is enriched in soluble factors which facilitate (1) inflammation-related cancer progression and immune escape and (2) cancer cell proliferation and resistance to anticancer therapies. Our results demonstrate that senescence is associated with mitochondrial dysfunction depending on TRPC3 bioavailability and is characterised by the release of pro-inflammatory chemokines, cytokines and other inflammation-related cancer progression factors which facilitate (1) inflammation-related cancer progression and immune escape and (2) cancer cell proliferation and resistance to anticancer therapies. Our results demonstrate that senescence is associated with mitochondrial dysfunction depending on TRPC3 bioavailability and is characterised by the release of pro-inflammatory chemokines, cytokines and other tumour-promoting molecules (Fig. 8a–c). Besides the pro-inflammatory chemokines and cytokines evoking the induction of the IL-1-regulated arm of SASP, some of the soluble factors released by fibroblasts upon TRPC3 downregulation such as IL-8, HGF, ENA-78, CXCL5, RANTES, PDGF Rb and MMP1 directly stimulate tumour growth and resistance to chemotherapy or contribute to tumour progression in vivo (Fig. 8b–g)$^{37,40}$. However, the discrepancies observed between the rate of cell proliferation in vitro and tumour growth in vivo strongly suggest the contribution of some other factors to the latter.

Altogether, our findings pinpoint TRPC3 as a key regulator of intracellular Ca$^{2+}$ events engaged in senescence affecting SASP production and thereby tumour progression.

Methods

Cell lines and primary cultures. Human primary lung embryonic fibroblasts MRC5 (PD 5–40, ATCC, USA) and Virus-packaging GP293 cells (Clontech, USA)
were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% foetal bovine serum and penicillin/streptomycin 100 U ml⁻¹. Human primary prostate fibroblasts (PD 0-15, ScienCell, USA) were cultured in MCDB131 medium (Biological Industries, Israel) supplemented with 10% foetal bovine serum, 10 mM Hepes, 1 ng ml⁻¹ bFGF and 0.1 ng ml⁻¹ EGF. CAFs from human prostate cancer biopsies were obtained by explant as described in our previous paper⁶¹. PC3, PC3-Luc and DU145 epithelial prostate cancer cells (ATCC) were cultured in RPMI 1640 supplemented with 10% FBS and 1% L-glutamine. HEK293T
Fig. 6 Silencing of TRPC3 promotes spontaneous Ca\(^{2+}\) oscillations and transient membrane depolarisations in mitochondria. a–c Ratiometric confocal [Ca\(^{2+}\)]\(_{\text{mito}}\) imaging (at 0.2 Hz) was performed in fibroblasts expressing GEM-GECO1mito and transduced with either shCTRL (a) or shTRPC3 (b). The plots (top) show temporal profiles of the GEM-GECO1mito self-normalised fluorescence ratio (ΔF/ΔR\(_{\text{R0}}\)) where R\(_{\text{R0}}\) is a mean of at least 50 sample minimums of R) for four cells. The galleries (bottom) show every 50th image (overlay of 2 channels: BP 470–500 nm plus LP > 520 nm) captured during entire observation period (traces: top). c The bar diagram plot compares corresponding mean signal temporal densities, calculated as signal mass (\(\int (\Delta F/\Delta R_{\text{R0}})\)) per second, in shCTRL (n = 9) and shTRPC3 fibroblasts (n = 11). ***P < 0.001, Student’s t-test, two-sided. d f Changes in the mitochondrial membrane potential (at 0.1 Hz) were monitored in TMRE-loaded fibroblasts transduced with either shCTRL (d) or shTRPC3 (e). The plots (middle) show temporal profiles of the TMRE self-normalised fluorescence ratio (ΔF/F\(_{\text{R0}}\)) at 5 boxed (top) regions of interest (ROIs), as indicated. The galleries (bottom) show every 2nd image (left to right, top to bottom) captured at corresponding ROIs. f The bar diagram plot compares corresponding mean signal temporal densities in shCTRL (n = 6; 75 ROIs) and shTRPC3 (n = 5; 92 ROIs) fibroblasts. ***P < 0.001 (Student’s t-test, two-sided).

Virus production, gene transfer and gene silencing. To produce retroviral particles, GP293 packaging cells were cultured in DMEM containing 10% FBS. The cells were maintained at 37 °C under a 10% CO\(_2\) atmosphere.

Wild-type “TRPC3-Myc”, a gift from Craig Montell (Addgene plasmid # 25902), CEBPα mutants E630K-E630Q, and the pore mutants “TRPC3-MRK/AAA” were cloned into the baculoviral vector pFastBac LIC, a gift from Robert Campbell (Addgene plasmid # 32461), into the plnCX2 vector by BamHI-BglII/HindIII.

EGFP-TRPC3 was produced by E-Zvec (France) and cloned into the plnCX2 vector by Sall/ClaI.

Co-immunoprecipitation, immunoblotting and antibody arrays. For western blots, cells lysis was performed with different solutions depending on the analysed proteins and protocols. The total protein content was measured using the BCA assay. Immunoprecipitation was performed on cell lysates prepared as above and diluted in 1 ml of lysis buffer. Agarose-Protein A/G beads (SantaCruz) were incubated either with rabbit anti-TRPC3 (5 μg/ml lysate) or rabbit anti-IP3 (5 μg/ml lysate) for 3 h at +4 °C. Proteins were then incubated overnight at +4 °C with the Ab-coupled beads and washed five times in IP buffer followed by western blot.

Quantitative real-time PCR. Total RNA was prepared using the NucleoSpin® RNA Plus (Machery Nagel). Two μg of RNA were reverse-transcribed using random hexamers, MuLV and dNTPs (Life Technologies) in a final volume of 20 μl according to manufacturer’s instructions. Quantitative Real-time PCR reactions were performed using the CFX96 Real-time PCR system (BioRad). Primers were designed with the qPrimerDepot software (http://primerdepot.nci.nih.gov/) and are listed in Supplementary Table 2. For primers used to amplify TRP transcripts, see the Declaration of Interests. PCR products were measured by EVA Green fluorescence (SoFast™ EvaGreen® Supermix, Bioxid). Experiments were performed in triplicate and each data point was analysed with the CFX Manager version 3.1 software (BioRad). Gene expression was normalised to GAPDH, ACTIN or 18S gene, and fold expression relative to the control is shown.

For absolute qPCR, plasmids containing the sequences for human IP1, R1, IP2, R2 and IP3 and for GP64 viral glycoprotein were serially diluted to obtain a calibration curve and used in a standard reaction.

SA-β-Gal analysis and growth assay. SA-β-Gal activity was determined according to Debaq-Chainaux F et al., for cytometry and flow cytometry, except that C12FDG was replaced by 10 μM DDAOG (Gong et al., 2009).
Confocal microscopy. Confocal imaging was performed with LSM 510 META confocal workstation using a Plan-NeoFluar ×40 1.3 NA objective (Carl Zeiss, Germany). Fluo-4, Mitotracker Green and eGFP were excited by the 488 nm line of 500 mW Argon ion laser (Laser-Fertigung, Hamburg, Germany) and fluorescence was captured at wavelengths 505–545 nm. TMRE and ER-Tracker Red were excited by the 543 nm line of 5 mW He/Ne laser (Laser-Fertigung, Hamburg, Germany) and the fluorescence was captured at wavelengths >560 nm. CellMask Deep Red was excited by the 633 nm line of 15 mW He/Ne laser (Laser-Fertigung, Hamburg, Germany) and the fluorescence was captured at wavelengths >650 nm.
Fig. 7 Relief of the TRPC3-mediated inhibition of IP3Rs promotes senescence via facilitation of ER-mitochondria Ca\textsuperscript{2+} transfer, alteration of mitochondrial metabolism and ROS production. a The galleries (from left to right) show the confocal images of the GO-A Team probe fluorescence excited at 488 nm and captured at wavelengths of 500-520 nm, >550 nm and their overlay. The bar diagram plot (right) compares mean ATP levels (estimated as F500–550/F>550) in the MRC5 transfected with siCTRL (n = 162) or siTRPC3 (n = 178). *P < 0.001 relative to siCTRL (Student’s t test, two-sided). b Oxygen consumption rate (OCR) is expressed as pmol O₂ min⁻¹ 50,000 cells⁻¹ measured using the Seahorse XFe24 technology (mean ± SD; n = 4) in fibroblasts transfected with either siCTRL, siTRPC3 or siIP3R3. Inhibitors have been injected as indicated by arrows: Oligomycin A (Oli.), carbonyl cyanide-4-(trifluoromethoxy)phenylhydrazide (FCCP) and rotenone and antimycin A (Rot/AA). c and d States of mitochondrial respiration are “basal” (c) for basal respiration and “ATP Turnover” (d) for ATP-linked OCR (basal measurement minus oligomycin response). Mean ± SD; n = 4 (one-way ANOVA followed by Tukey's post-test *P < 0.05). See also Supplementary Fig. 6e–g. e Confocal images of Mitosox Green and MitoTracker Deep Red fluorescence (top) and bar diagram plot (bottom) of Mitosox/MitoTracker fluorescence ratio comparing mitochondrial ROS production in fibroblasts transfused either with siCTRL (n = 74) or siTRPC3 (n = 143) and in siP2R3-transfected fibroblasts transfused with siTRPC3 (n = 74). Mean ± SD 1*P < 0.001, **P < 0.01 (one-way ANOVA, Tukey's multiple comparisons test).

To verify optical channel setting for ratiometric confocal [Ca\textsuperscript{2+}]\textsubscript{i} imaging, fluorescence emission spectra of GEM-CPEA1er and GEM-GECO1mito expressed in fibroblasts were measured after stimulation with 10 μM of Fluo-4 (Sigma) and 0.5 μM of Fluo-4 (GEM-CPEA1).mito, or in control and after application of 2.5 μM ionomycin (for GEM-GECO1 mito). Fluorescence was excited by 405 nm line of blue diode laser and captured by META unit of LSM 510 META confocal workstation. Upon time-series [Ca\textsuperscript{2+}]\textsubscript{i} imaging, fluorescence then was captured at the two channel: green—470–500 nm and red—>550 nm in line-by-line mode of the multitrack configuration of the confocal scanner. Illumination intensity was attenuated to 0.6–4% (depending on fluorophore used) with an acousto-optical tunable filter.

Image processing was carried out using LSM 5 software (Zeiss, Oberkochen, Germany) and with custom routines written in IDL (Research Systems, Inc., Boulder, CO, USA).

Fura-2 was alternatively excited at 340 and 380 nm with a monochromator (Polychrome IV; TILL Photonics) and was captured after filtration through a long-pass filter (510 nm) by a 5 MHz charge-coupled device camera (MicroMax; Princeton Instruments). Acquisition and analysis were performed with Metafluor 4.5 software (Universal Imaging Corp.).

Organelle membrane-derived patches. The collection of the ER-containing fractions from prostate fibroblasts transfused either with empty vector or TRPC3, the preparation of GUVs and the patch-clamping were performed following the protocol described in our previous paper43.

Flow cytometry. Flow cytometry was performed using a CYAN AD (Beckton Coulter, USA) and the Summit Software version 4.3. Briefly, 1 × 10⁶ cells were incubated with 5 μl of Pacific Blue Annexin V and 5 μl of 7-AAD for 15 min at +4°C. Collected data were exported to and analysed with the FlowJo 7.0 software (FlowJo, LLC).

Mitochondrial membrane potential. Mitochondrial membrane potential flickers were analysed by utilising the TMRE probe (0.1 μM). Cells were incubated with TMRE for 1 min and analysed by confocal microscopy to determine the number of flickers over a time period of 5 min.

NAD\textsuperscript{+}/NADH and ADP/ATP ratios. MRC5 cells were transfected with siTRPC3 of siCTRL and cultured for 7 days. Cells were then plated in 96-well plates for measurements. The NAD\textsuperscript{+}/NADH ratio was determined using the NAD/NADH-Glo Assay (Promega, G9071) according to the manufacturer's instructions. The ADP/ATP ratio was determined using an ADP/ATP Ratio Assay kit (Sigma, cat. no. MAK135) according to the manufacturer's instructions. Luminescence signals were captured using a TriStar S LB 942 microplate reader (Berthold).

Mitochondrial respiration. Oxygen consumption rates (OCR) were measured using the XFe24 Extracellular Flux Analyser (AgilentTechnologies, Les Ulis, France). Briefly, culture medium was removed and cells were washed once with DMEM (Sigma-Aldrich), pH buffered at 7.35, supplemented with 10 mM glucose and 2 mM glutamine. Then, cells were incubated with DMEM in CO₂-free chamber at 37 °C for 30 min. Baseline OCR was measured: (i) at the basal state, (ii) after oligomycin (Oli.) injection (1 μM), (iii) after FCCP injection (0.27 μM and then 0.34 μM), and (iv) after rotenone and antimycin A (Rot/AA) mix injection (1 μM).

Assessment of mitochondrial ROS levels. Mitochondrial ROS levels were measured by incubating cells with MitosoxGreen and MitoTracker Deep Red probes (Life Technologies) for 30 min in culture medium. Cells were washed twice in phenol-red free culture medium and analysed by confocal microscopy. ROS levels were estimated by calculating the mean fluorescence ratio Mitosox/MitoTracker.

Animal study. NOD-SCID mice (NOD.CB17-Prkdcscid/IcrHsd) 5 weeks old, male, weight were purchased from Envigo (Gannat, France), maintained in laminar flow boxes under standard conditions (standard diet and water ad libitum) at 23 °C with 12-h light and 12-h dark cycles at Animal Facility Core (University of Lille, France) under Specific Pathogen Free (SPF) conditions. After one week of quarantine and acclimatisation, the mice were earmarked and randomly separated into 2 groups of 10 subjects, 5 animals/cage, by an independent person. Animal study was approved by the Animal Experimentation Ethics Committee CEER Nord —Pas de Calais no. 75 (Permit No. 201706201532770), and all procedures were conducted in accordance with the French National Chart for Animal Experimentation and the ARRIVE guidelines.

To evaluate the effect of TRPC3 down regulation in HPRFs on the proliferative potential of prostate epithelial cancer cells, NOD-SCID mice were injected s.c. on the right flank with a mix of 1 × 10⁶ PC3-Luc cells and 0.5 × 10⁶ HPRFs stably expressing doxycycline-inducible shRNA against TRPC3 or scramble sequence (ratio 2:1) and previously treated for 7 days with doxycycline (1 μg ml⁻¹) to induce shRNAs expression, in vivo animal imaging was performed one day after injection and weekly by I.P. injection of 150 mg/kg D-XenoLight D-Luciferin (PerkinElmer—K⁺ salt bioluminescent Substrate (PerkinElmer, OH, USA) using the IVIS Spectrum optical imaging system (PerkinElmer) for a total of 6 weeks. Bioluminescence recording was performed using the Living Image software version 4.5 from PerkinElmer.

Public datasets analysis. Microarray datasets from Oncomine (“Grasso Prostate” and “Tamura Prostate”) were used to analyse the expression of TRPC3 in prostate cancer patients undergoing or not chemotherapy or radiotherapy. Log2 median-centred ratios for each patient were used to create the scatter plot.

Raw data (accession number GSE130727 and GSE35988) were downloaded from Gene Expression Omnibus. For GSE130727 dataset, normalisation and differential expression was done with “DESeq2” R package version 1.24.0 and R version 3.6.0. Lastly, we extracted normalised counts for TRPC3 on log scale for each condition and treatments (Supplementary Fig. 1I). For GSE35988 dataset, patients were classified using the median expression of the TRPC3 gene. Differentially expressed genes (DEGs), were identified using the Linear Models for Microarray and RNA-Seq Data limma package v3.46.0 and R 3.6.0. Fold changes were calculated after loess within-normalisation and quantile between-normalisation. Duplicate probes were replaced with their average using the limma ‘averses’ function. A total of 1585 up-regulated and 1801 down-regulated genes were identified with a cut-off value of absolute log fold change (logFC) > 0.5 and an adjusted p-value < 0.05 (Benjamini-Hochberg).

Gene Set Enrichment Analysis (GSEA) was performed using the GSEA software version 4.1.0 from UC San Diego and Broad Institute, using the Human Cellular Senescence Gene Database (HCSGD)35. All probe sets were pre-ranked using a metric defined as the sign(logFC) — log10(p-value)⁶; thereafter, the ordered probe set list was used as the pre-ranked GSEA input. Detailed GSEA parameters are as follows: the number of permutations is 1000, min size is 15 and max size is 500.

Statistical analysis. Error bars represent either the SD or SEM, as described in figure legends. Sample size for each experiment, n, is included in the associated figure legend. Statistic significance was determined by the Student’s t test and the one-way ANOVA using GraphPad Prism 8.0. p values < 0.05 were considered significant. p values for each experiment are also included in the associated figure legend.
**Fig. 8** TRPC3 knockdown-induced senescence is responsible for the pro-tumour behaviour of prostate stromal cells. a Heatmap showing the log2 fold change in secreted SASP, as revealed by antibody arrays, by CAFs treated with siTRPC3 and compared to siCTRL cells (n = 3, multiple T-test, two-sided, Holm–Sidak correction for multiple comparisons). b Bar diagram plot comparing cell proliferation measured with MTS proliferation assay in PC3 (left) and DU145 (right) cell lines cultured in: (1) non-conditioned medium (NCM), (2) conditioned medium from the siCTRL-transfected CAFs (CAFs siCTRL CM) and (3) conditioned medium from the siTRPC3-transfected CAFs (CAFs siTRPC3 CM). The readings (light absorption) from PC3 or DU145 cells obtained in CAFs siCTRL CM and CAFs siTRPC3 CM were normalised to corresponding readings obtained in NCM and expressed as % (mean ± SEM, n = 3: one-way ANOVA, Tukey’s multiple comparisons test). c Same as in (b) but illustrating cell lines cultured in conditioned medium from: (1) control cells, (2) hRAS-overexpressing cells (hRAS), (3) hRAS + TRPC3-overexpressing cells or (4) cells overexpressing TRPC3 alone (mean ± SEM, n = 3: one-way ANOVA, Tukey’s multiple comparisons test). d Bar diagram plot comparing survival of PC3 and DU145 cells (as indicated) after doxetaxel treatment between the cell groups described in (b). The same measurements were done on the cells exposed to DMSO (vehicle) instead of doxetaxel. Chemotherapy-resistance was expressed as a ratio of the cell survival observed after treatment with doxetaxel to that observed with vehicle only and expressed in % (mean ± SEM, n = 3: one-way ANOVA, Tukey’s multiple comparisons test). e Time course (6 weeks) of the bioluminescence mean (10 mice; + SD) total flux (top) and underlying individual traces (bottom) obtained 15 min after luciferin administration. The mice, continuously admitting doxycycline, were injected with PC3-Luc cells mixed with either siCTRL-transduced (black line) or siTRPC3-overtransduced (red line) HPFs. **P < 0.001, "P < 0.01 (one-way ANOVA, Tukey’s multiple comparisons test). f Bioluminescence images of oxidised luciferin from 3 mice of the two groups (panel e) on the 6th week after tumour challenge. g Comparison of sizes from tumours collected 6 weeks after tumour challenge. Scale bar: 0.5 cm.

**Reporting summary.** Further information on research design is available in the Nature Research Reporting Summary linked to this article.

**Data availability**

The processed GSE130727 and GSE35988 datasets used to analyse TRPC3 expression in senescence (Supplementary Fig. 11-L) are available in Gene Expression Omnibus (GEO) and in Oncomine Database (https://www.oncomine.org) identified as “Grasso Prostate” and “Tamura Prostate”. The dataset used to calculate gene enrichment (Supplementary Fig. 1M) is available on the Human Cellular Senescence Database (HCSGD). The individual data point sets for the remaining figures are available in the Source File provided with this manuscript. Source data are provided with this paper.
