Abstract

This report describes a case of generalized chronic periodontitis requiring periodontal regenerative therapy. The patient was a 62-year-old man who presented with the chief complaint of gingival swelling in the molar region. An initial examination revealed that 31.6% of sites had a probing depth of ≥4 mm and 18.5% bleeding on probing. Radiographic examination revealed vertical bone resorption in #14, 25, 26, 27, 32, 37, 45, and 47, and horizontal resorption in other regions. Based on a clinical diagnosis of moderate chronic periodontitis, initial periodontal therapy consisting of plaque control and scaling and root planing was performed. Occlusal adjustment of premature contact sites was performed after inflammation was suppressed. Surgical periodontal therapy was subsequently performed at selected sites. Periodontal regenerative therapy using recombinant human fibroblast growth factor (rhFGF)-2 was performed on #14, 25, 26, 32, and 37. Combination therapy with rhFGF-2 and deproteinized bovine bone mineral (DBBM) was performed on #45 and 47. Other sites with residual periodontal pockets were treated by open flap debridement, and #27 was extracted due to a bone defect exceeding the root apex. Progress was then reevaluated and the patient placed on supportive periodontal therapy. Periodontal regenerative therapy using rhFGF-2 in combination with DBBM resulted in an improvement in clinical parameters and vertical bone resorption. This improvement has been adequately maintained over an 18-month period. The periodontal treatment provided resulted in a marked improvement in the patient’s oral health-related quality of life.

Key words: Chronic periodontitis — Intrabony defects — Periodontal regenerative therapy — Recombinant human fibroblast growth factor (rhFGF)-2 — Deproteinized bovine bone mineral
Introduction

Periodontal regeneration has become the ideal goal in the treatment of periodontal lesions since the demonstration of the possibility of new attachment with the formation of cementum and periodontal ligament\(^{16}\). Recently, various regenerative techniques have been proposed for the treatment of periodontitis with intrabony defects. In 2016, the use of 0.3% recombinant human fibroblast growth factor (rhFGF)-2 for periodontal regeneration was formally approved in Japan. Recombinant human fibroblast growth factor stimulates proliferation, differentiation, and angiogenesis in a variety of cells, and has been reported to be effective in regenerating periodontal tissue in pre-clinical models\(^{15,23}\). Previous in vivo studies by the present group showed that rhFGF-2 enhanced periodontal healing in an animal model\(^{2,6}\). The use of rhFGF-2 has been shown to be effective in periodontal regenerative therapy in clinical trials\(^{8-11}\). Furthermore, one randomized controlled clinical trial has shown that rhFGF-2 yielded a greater radiographic bone fill than enamel matrix derivative (EMD) in intrabony defects\(^{9}\). However, due to its fluid consistency, rhFGF-2 appears to possess limited space-making potential, which, in defects with a more complicated anatomy, may not be able to prevent the collapse of a mucoperiosteal flap, thus limiting the available space for regeneration.

One comparative controlled clinical trial found that combining deproteinized bovine bone mineral (DBBM) with EMD, a biological agent, yielded greater improvement in clinical and radiographical outcomes than with EMD alone at 1 year postoperatively\(^{25}\). Recently, the present research group showed that combined use of rhFGF-2 and DBBM yielded an enhanced radiographic outcome at 6 months postoperatively in the treatment of intrabony defects\(^{21}\). This suggests that combination therapy with rhFGF-2 and DBBM is an effective treatment modality. Here, we report a case of chronic periodontitis with intrabony defects in which periodontal regenerative therapy with rhFGF-2 and DBBM resulted in improvements that were sustained for more than 18 months of postoperative follow-up.

Case Presentation

This case represents part of a longitudinal clinical study investigating clinical outcomes of regenerative therapy with rhFGF-2 and DBBM which was approved by the Ethics Committee of Tokyo Dental College (Approval No: 747). Written informed consent was obtained from the patient for study participation and inclusion in this report.

1. Baseline examination

In May 2017, a 62-year-old man visited the Clinic of Conservative Dentistry at the Tokyo Dental College Chiba Dental Center with the chief complaint of gingival swelling in the molar region. The general health of the patient was good. The patient had first become aware of gingival swelling approximately 3 years earlier. He had received some initial periodontal treatment and had had regular check-ups every 3 months at a local dental office. In 2016, the symptoms of his periodontitis had begun to worsen, however, and as there appeared to be no subsequent improvement, his dentist referred him to our clinic for treatment. Figure 1 shows the oral view obtained at his first visit. Gingival inflammation and subgingival calculus were mostly evident in the molar region. Gingival recession was observed in #32. Premature contact was observed in #27 and 37.

The results of a periodontal examination (see Fig. 2) revealed that 31.6% of sites had a probing depth (PD) of ≥4 mm and 6% a PD of ≥6 mm. Bleeding on probing (BOP) was observed at 18.5% of sites. The level of plaque control as assessed according to the O’Leary plaque control record (PCR)\(^{18}\) was 42%. Radiographic examination (Fig. 3) revealed angular bone defects in #14, 25, 26, 27, 32, 37, 45, and 47. Furcation involvement was Degree
1 for #27. As a measure of patient-reported outcome, oral health-related quality of life (QoL) was assessed using an oral health-related QoL instrument (OHRQL)\(^2\). The total OHRQL score was 19.

2. Diagnosis

The clinical diagnosis was Stage III, Grade B generalized chronic periodontitis\(^1\)(\(^3\)). A treatment plan was presented to the patient and his consent to the proposed plan obtained.

---

**Clinical Procedures and Outcomes**

1. **Treatment plan**

   This comprised oral hygiene instruction, quadrant scaling and root planing (SRP), root canal treatment in #27, and occlusal adjustment for #27 and 37.

2. **Reevaluation**

3. **Periodontal surgery**

   Periodontal surgery for sites with a PD of \(\geq 4\) mm. Periodontal regenerative therapy with rhFGF-2 for #14, 25, 26, 27, 32, 37, 45, and 47.
2. Treatment process

An outline of the treatment process is shown in Table 1.

1) Initial periodontal therapy

After obtaining informed consent for the proposed treatment plan, instruction was given on maintaining oral hygiene and quadrant SRP performed. Root canal treatment was performed for #27. Occlusal adjustment was implemented for #27 and 37.

2) Reevaluation

Subsequent reevaluation revealed a reduction in the PCR score to 19% and a decrease to 15.3% and 4.8% for sites with a PD of ≥4 mm and 6 mm, respectively. The OHRQL total score was 13. Closed pockets were observed in 18.7% of the teeth and BOP in 13.1%. These results were judged to be “insufficient” according to the criteria for the success of non-surgical periodontal therapy.

3) Periodontal surgery

Based on the results of the reevaluation, the need for periodontal surgery was explained and informed consent for its implementation obtained. Regenerative therapy with rhFGF-2 [REGROTH Dental Kit, 600 μg in hydroxypropyl cellulose, Kaken Pharmaceutical, Tokyo, Japan] and DBBM (Geistlich Bio-Oss, 0.25–1.0 mm granules, Geistlich Pharma AG, Wolhusen, Switzerland) was then performed on #45 and 47 for deep intrabony defects (Fig. 4). Subsequently, regenerative therapy with rhFGF-2 was performed on #14, 25, 26, 32, and 37. Open flap debridement was implemented for #15, 16, 17, 31, 33, 35, 36, 41, 42, and 43 to reduce periodontal pockets. Intraoperatively, #27 had to be extracted due to a bone defect exceeding the root apex.

4) Reevaluation

On reevaluation, gingival inflammation showed an improvement. Sites with a PD of ≥4 mm and BOP had disappeared.

5) Treatment for recovery of oral function

The patient complained of poor esthetics and requested a new prosthesis. A CAD/CAM resin crown was then placed on #14.

6) Reevaluation

On reevaluation, an improvement was observed in gingival inflammation and PD (Fig. 5 and 6). The patient’s level of plaque control was good (PCR <20%). Various levels of improvement were observed radiographically at those sites selected for regenerative therapy (Fig. 7). The periodontal conditions were judged to be stable, and the patient was placed in a recall system for SPT.

Fig. 4  Periodontal regenerative therapy with rhFGF-2 and DBBM (#45, 47)
(a) (b) Preoperative radiograph. (c) Intra-operative view. (d) rhFGF-2 mixed with DBBM.
(e) After debridement and rinsing, filled with rhFGF-2. (f) Defects were completely filled
with rhFGF-2 and DBBM. Care was taken not to overfill defects. (g) (h) 18 months of SPT.

7) SPT
Over 18 months of SPT, pockets with a PD of 4 mm were found in #17 (Fig. 9), but the
periodontal condition remained stable in most of the teeth (Fig. 8 and 9). A 3.1-mm
gain in mean clinical attachment level (CAL) was observed in the teeth treated with rhFGF-2
(Fig. 11). In #45 and 47, combined treatment with rhFGF-2 and DBBM yielded CAL gains of
3.0 mm and 4.0 mm, respectively (Fig. 12). Distinct radiographic bone fill was observed
in the teeth treated with the combination of rhFGF-2 and DBBM (Fig. 4 and 10). The total
OHRQL score was 6, indicating an improve-

Discussion

Application of rhFGF-2 has been reported to greatly improve clinical outcomes and bone loss\(^\text{9-11}\). In the present case (SPT, 18 months), treatment of periodontal defects with rhFGF-2 alone yielded an improvement in PD and clinically relevant CAL gain at 18 months postoperatively (Fig. 11). Kitamura \textit{et al.} reported a mean gain in CAL of 2.7 mm at 9 months following rhFGF-2 therapy\(^\text{9}\). The 18-month results in the present case are in agreement with this earlier finding. However, periodontal regeneration in large circumferential defects without bony walls is considered difficult because it may not be possible to preserve space for regeneration of periodontal tissue or retain the blood clot to promote healing. According to an evidence-based decision tree proposed by Reynolds \textit{et al.}\(^\text{20}\), the combined use of supportive or filling materials is recommended in treating wide defects and/or non-contained defects\(^\text{20}\). This suggests that it is effective to use bone substitutes as a scaffold for regeneration.

There are multiple opinions regarding the effect of bone substitutes in combination regenerative therapy. According to a clinical practice guideline issued by the Japanese Society of Periodontology\(^\text{7}\), there is no clear evidence of an additional effect when a bone graft is applied in combination with guided tissue regeneration or EMD. This indicates...
the need to carefully consider different combinations of regenerative therapies, such as application of growth factor and bone substitutes. In one previous report, FGF-2 used in combination with beta-tricalcium phosphate ($\beta$-TCP) yielded a significant increase in new bone and cementum formation in comparison with an FGF-2-alone group in a dog model\textsuperscript{17}. In one multicenter randomized controlled trial evaluating the treatment of intrabony periodontal defects, rhFGF-2 used in combination with $\beta$-TCP improved clinical parameters at 6 months in comparison with $\beta$-TCP alone\textsuperscript{3}. The reported CAL gain with treatment comprising rhFGF-2 in combination with $\beta$-TCP was 3.0 mm at 6 months postoperatively. Saito et al. reported a mean gain in CAL of 3.16 mm at 6 months following rhFGF-2 and DBBM therapy\textsuperscript{21}. In the present case, treatment of periodontal defects with rhFGF-2 and DBBM yielded CAL gains of 3.0 mm and 4.0 mm, respectively at 18 months postoperatively (Fig. 12). This is consistent with findings from previous studies. However, caution has to be exercised when comparing these results, as there may have been differences in the initial probing depth or attachment level. In the present case, increases in radiopacity were confirmed at 3 months postoperatively after treatment with the combination of rhFGF-2 and DBBM, and further improvement was observed at 18 months (Fig. 4). One previous study showed that DBBM particles were still present after 4 years 6 months postoperatively with no clear signs of resorption\textsuperscript{5}. To prevent complications, it is necessary to continue long-term observation of change in radiopacity.

In the present case, the OHRQL score showed an improvement after initial periodontal therapy, a finding consistent with those in our own previous reports\textsuperscript{14}. We believe that this was due to the removal of the chief complaint and improvement of the oral environment with initial periodontal treatment. The OHRQL score worsened after surgical treatment compared with that at first visit, however. This may have been due to the patient experiencing postoperative discomfort, which might have included pain, swelling, or tooth sensitivity. We believe that this was not due to combined use of rhFGF-2 and DBBM. At the start of SPT, the OHRQL score appeared to improve compared to with that after surgical treatment. We speculate that resolution of discomfort after surgical treatment and recovery of oral function through the wearing of prosthetic appliances may have contributed to this improvement in QoL. In the present case, the OHRQL score remained stable during SPT.

The risk during the maintenance phase was determined to be low according to the Periodontal Risk Assessment\textsuperscript{13}. Several sites were found to be positive for BOP, however. Sites recognized as having BOP during SPT indicate a higher probability of periodontitis progression\textsuperscript{12}. Cugini et al. reported that maintenance scaling appeared to be important in sustaining post-therapy decreases in mean levels of subgingival microbiota over a prolonged period of time\textsuperscript{4}. In consideration of these earlier reports, the present patient was placed on a 3-month recall schedule for SPT, during which the level of oral hygiene was also checked.

In summary, periodontal treatment including regenerative therapy with rhFGF-2 and DBBM yielded a marked improvement in clinical parameters and radiographic bone fill. Careful SPT is scheduled to be continued.
