Abstract

A Galois connection between clones and relational clones on a fixed finite domain is one of the cornerstones of the so-called algebraic approach to the computational complexity of non-uniform Constraint Satisfaction Problems (CSPs). Cohen et al. established a Galois connection between finitely-generated weighted clones and finitely-generated weighted relational clones [SICOMP'13], and asked whether this connection holds in general. We answer this question in the affirmative for weighted (relational) clones with real weights and show that the complexity of the corresponding valued CSPs is preserved.

1 Introduction

The constraint satisfaction problem (CSP) is a general framework capturing decision problems arising in many contexts of computer science [16]. The CSP is NP-hard in general but there has been much success in finding tractable fragments of the CSP by restricting the types of relations allowed in the constraints. A set of allowed relations has been called a constraint language [12]. For some constraint languages, the associated constraint satisfaction problems with constraints chosen from that language are solvable in polynomial-time, whilst for other constraint languages this class of problems is NP-hard [12]; these are referred to as tractable languages and NP-hard languages, respectively. Dichotomy theorems, which classify each possible constraint language as either tractable or NP-hard, have been established for constraint languages over two-element domains [24], three-element domains [6], for conservative (containing all unary relations) constraint languages [8], for maximal constraint languages [9, 5], for graphs (corresponding to languages containing a single binary symmetric relation) [15], and for digraphs (corresponding to languages containing a single binary relation) without sources and sinks [2]. The most successful approach to classifying the complexity of constraint languages has been the algebraic approach [19, 7, 1]. The dichotomy conjecture of Feder and Vardi [12] asserts that every constraint language is either tractable or NP-hard, and the algebraic refinement of the conjecture specifies the precise boundary between tractable and NP-hard languages [7].

The valued constraint satisfaction problem (VCSP) is a general framework that captures not only feasibility problems but also optimisation problems [11, 34, 18]. A VCSP instance represents each constraint by a weighted relation, which is a $\overline{\mathbb{Q}}$-valued function where $\overline{\mathbb{Q}} = \mathbb{Q} \cup \{\infty\}$, and the goal

*The authors were supported by a Royal Society Research Grant. Stanislav Živný was supported by a Royal Society University Research Fellowship. A part of this work appeared in Proceedings of the 42nd International Colloquium on Automata, Languages, and Programming (ICALP), 2015 [13].
is to find a labelling of variables minimising the sum of the values assigned by the constraints to that labelling. Tractable fragments of the VCSP have been identified by restricting the types of allowed weighted relations that can be used to define the valued constraints. A set of allowed weighted relations has been called a \textit{valued constraint language} [11]. Dichotomy theorems, which classify each possible valued constraint language as either tractable or NP-hard, have been established for valued constraint languages over two-element domains [11], for conservative (containing all \{0, 1\}-valued unary cost functions) valued constraint languages [22], for finite-valued (all weighted relations are \(\mathbb{Q}\)-valued) constraint languages [27]. Moreover, it has been shown that a dichotomy for constraint languages implies a dichotomy for valued constraint languages [20]. Finally, the power of the basic linear programming relaxation [26, 21] and the power of the Sherali-Adams relaxation [30, 29] for valued constraint languages have been completely characterised.

Cohen et al. have introduced an algebraic theory of weighted clones [10], further extended in [28, 23], for classifying the computational complexity of valued constraint languages. This theory establishes a one-to-one correspondence between valued constraint languages closed under expressibility (which does not change the complexity of the associated class of optimisation problems), called weighted relational clones, and weighted clones [10]. This is an extension of (a part of) the algebraic approach to CSPs which relies on a one-to-one correspondence between constraint languages closed under pp-definability (which does not change the complexity of the associated class of decision problems), called relational clones, and clones [7], thus making it possible to use deep results from universal algebra. This theory has been developed primarily as an aid for studying the computational complexity of valued CSPs (and indeed, recent progress on valued CSPs [26, 27, 21, 30, 20] and on special cases of valued CSPs [31] heavily rely on the theory introduced in [10]), but the theory is interesting in its own right [28, 23, 33, 32].

**Contributions**

The Galois connection between weighted clones and weighted relational clones established in [10] was proved only for weighted (relational) clones generated by a \textit{finite} set. The authors asked whether such a correspondence holds also for weighted (relational) clones in general. In this paper we answer this question in the affirmative.

Firstly, we show that the Galois connection from [10] (using only rational weights) does \textit{not} work for general weighted (relational) clones. Secondly, we alter the definition of weighted (relational) clones and establish a new Galois connection that holds even when the generating set has an infinite size. We allow weighted relations and weightings to assign real weights instead of rational, require weighted relational clones to be closed under operator \(\text{Opt}\) and to be topologically closed, and prove that these changes preserve tractability of a constraint language (albeit only in an approximate sense).

Including the \(\text{Opt}\) operator (sometimes called \text{argmin})\textsuperscript{1} in the definition of weighted relational clones simplifies the structure of the space of all weighted clones, and guarantees that every non-projection polymorphism of a weighted relational clone \(\Gamma\) is assigned a positive weight by some weighted polymorphism of \(\Gamma\). Indeed, including the \(\text{Opt}\) operator is very natural and can be used to simplify several results in [23]. Real weights (as opposed to rational weights) were previously used, in the context of valued CSPs, in [27] and our results confirm that real weights are necessary when studying infinite weighted (relational) clones.

---

\textsuperscript{1}Given a \(k\)-ary function \(f : D^k \to \mathbb{Q}\), \(\text{Opt}(f)\) is the \(k\)-ary relation over \(D\) of minimal-value tuples of \(f\).
2 Background

2.1 Valued CSPs

Throughout the paper, let $D$ be a fixed finite set of size at least two.

**Definition 1.** An $m$-ary relation\(^2\) over $D$ is any mapping $\phi : D^m \to \{c, \infty\}$ for some $c \in \mathbb{Q}$. We denote by $R_D^{(m)}$ the set of all $m$-ary relations and let $R_D = \bigcup_{m \geq 1} R_D^{(m)}$.

Given an $m$-tuple $x \in D^m$, we denote its $i$th entry by $x[i]$ for $1 \leq i \leq m$.

Let $\mathbb{Q} = \mathbb{Q} \cup \{\infty\}$ denote the set of rational numbers with (positive) infinity.

**Definition 2.** An $m$-ary weighted relation over $D$ is any mapping $\gamma : D^m \to \mathbb{Q}$. We denote by $\Phi_D^{(m)}$ the set of all $m$-ary weighted relations and let $\Phi_D = \bigcup_{m \geq 1} \Phi_D^{(m)}$.

From Definition 2 we have that relations are a special type of weighted relations.

**Example 3.** An important example of a (weighted) relation is the binary equality $\phi_\sim$ on $D$ defined by $\phi_\sim(x, y) = 0$ if $x = y$ and $\phi_\sim(x, y) = \infty$ if $x \neq y$.

Another example of a relation is the unary empty relation $\phi_\emptyset$ defined on $D$ by $\phi_\emptyset(x) = \infty$ for all $x \in D$.

For any $m$-ary weighted relation $\gamma \in \Phi_D^{(m)}$, we denote by Feas$(\gamma) = \{x \in D^m | \gamma(x) < \infty\} \in R_D^{(m)}$ the underlying feasibility relation, and by Opt$(\gamma) = \{x \in \text{Feas}(\gamma) | \gamma(x) \leq \gamma(y) \text{ for every } y \in D^m\} \in R_D^{(m)}$ the relation of minimal-value tuples.

**Definition 4.** Let $V = \{x_1, \ldots, x_n\}$ be a set of variables. A valued constraint over $V$ is an expression of the form $\gamma(x)$ where $\gamma \in \Phi_D^{(m)}$ and $x \in V^m$. The number $m$ is called the arity of the constraint, the weighted relation $\gamma$ is called the constraint weighted relation, and the tuple $x$ the scope of the constraint.

We call $D$ the domain, the elements of $D$ labels (for variables), and say that the weighted relations in $\Phi_D$ take values or weights.

**Definition 5.** An instance of the valued constraint satisfaction problem (VCSP) is specified by a finite set $V = \{x_1, \ldots, x_n\}$ of variables, a finite set $D$ of labels, and an objective function $I$ expressed as follows:

$$I(x_1, \ldots, x_n) = \sum_{i=1}^{q} \gamma_i(x_i),$$

where each $\gamma_i(x_i)$, $1 \leq i \leq q$, is a valued constraint over $V$. Each constraint can appear multiple times in $I$.

The goal is to find an assignment (or a labelling) of labels to the variables that minimises $I$.

\(^2\)An $m$-ary relation $R$ over $D$ is commonly defined as a subset of $D^m$. For the corresponding mapping $\phi : D^m \to \{0, \infty\}$ it holds $\phi(x) = 0$ when $x \in R$ and $\phi(x) = \infty$ otherwise. We shall use both definitions interchangeably. Because two mappings that differ only by a constant are usually equivalent for our purposes, we consider mappings $D^m \to \{c, \infty\}$ to be relations even if $c \neq 0$. 

The proof of the Galois connection in [10] relies on results on linear programming duality; we use their generalisation from the theory of convex optimisation in order to establish the connection even for infinite sets.
CSPs are a special case of VCSPs using only (unweighted) relations with the goal to determine
the existence of a feasible assignment.

Definition 6. Any set \( \Gamma \subseteq \Phi_D \) is called a \textit{(valued) constraint language} over \( D \), or simply a
\textit{language}. We will denote by VCSP(\( \Gamma \)) the class of all VCSP instances in which the constraint
weighted relations are all contained in \( \Gamma \).

Definition 7. A constraint language \( \Gamma \) is called \textit{tractable} if VCSP(\( \Gamma' \)) can be solved (to optimality)
in polynomial time for every finite subset \( \Gamma' \subseteq \Gamma \), and \( \Gamma \) is called \textit{intractable} if VCSP(\( \Gamma' \)) is NP-hard
for some finite \( \Gamma' \subseteq \Gamma \).

We refer the reader to a recent survey \[18\] for more information on the computational complexity
of constraint languages.

2.2 Weighted relational clones

Definition 8. A weighted relation \( \gamma \) of arity \( r \) can be obtained by \textit{addition} from the weighted
relation \( \gamma_1 \) of arity \( s \) and the weighted relation \( \gamma_2 \) of arity \( t \) if \( \gamma \) satisfies the identity
\[
\gamma(x_1, \ldots, x_r) = \gamma_1(y_1, \ldots, y_s) + \gamma_2(z_1, \ldots, z_t)
\] (2)
for some (fixed) choice of \( y_1, \ldots, y_s \) and \( z_1, \ldots, z_t \) from amongst \( x_1, \ldots, x_r \).

Definition 9. A weighted relation \( \gamma \) of arity \( r \) can be obtained by \textit{minimisation} from the weighted
relation \( \gamma' \) of arity \( r + s \) if \( \gamma \) satisfies the identity
\[
\gamma(x_1, \ldots, x_r) = \min_{(y_1, \ldots, y_s) \in D^s} \gamma'(x_1, \ldots, x_r, y_1, \ldots, y_s). 
\] (3)

Definition 10. A constraint language \( \Gamma \subseteq \Phi_D \) is called a \textit{weighted relational clone} if it contains
the binary equality relation \( \phi_e \) and the unary empty relation \( \phi_\emptyset \), and is closed under addition,
minimisation, scaling by non-negative rational constants, and addition of rational constants.

For any \( \Gamma \), we define wRelClone(\( \Gamma \)) to be the smallest weighted relational clone containing \( \Gamma \).

Note that for any weighted relational clone \( \Gamma \), if \( \gamma \in \Gamma \) then Feas(\( \gamma \)) \( \in \Gamma \) as Feas(\( \gamma \)) = 0\( \cdot \gamma \) (we
define 0 \cdot \infty = \infty \).

Definition 11. Let \( \Gamma \subseteq \Phi_D \) be a constraint language, \( I \in \text{VCSP}(\Gamma) \) an instance with variables \( V \),
and \( L = (v_1, \ldots, v_r) \) a list of variables from \( V \). The \textit{projection} of \( I \) onto \( L \), denoted \( \pi_L(I) \), is the
\( r \)-ary weighted relation on \( D \) defined as
\[
\pi_L(I)(x_1, \ldots, x_r) = \min_{\{s : V \to D \mid (s(v_1), \ldots, s(v_r)) = (x_1, \ldots, x_r)\}} I(s). 
\] (4)

We say that a weighted relation \( \gamma \) is \textit{expressible} over a constraint language \( \Gamma \) if \( \gamma = \pi_L(I) \) for some
\( I \in \text{VCSP}(\Gamma) \) and list of variables \( L \). We call the pair \( (I, L) \) a \textit{gadget} for expressing \( \gamma \) over \( \Gamma \).

The list of variables \( L \) in a gadget may contain repeated entries. The minimum over an empty
set is \( \infty \).

\(^3\) Although the definition in \[10\] does not require the inclusion of \( \phi_\emptyset \), the proofs there implicitly assume its presence
in any weighted relational clone.
Example 12. For any $\Gamma \subseteq \Phi_D$, we can express the binary equality relation $\phi_=$ on $D$ over language $\Gamma$ using the following gadget. Let $I \in \text{VCSP}(\Gamma)$ be the instance with a single variable $v$ and no constraints, and let $L = (v, v)$. Then, by Definition 11, $\pi_L(I) = \phi_=$.

We may equivalently define a weighted relational clone as a set $\Gamma \subseteq \Phi_D$ that contains the unary empty relation $\phi_0$ and is closed under expressibility, scaling by non-negative rational constants, and addition of rational constants [10, Proposition 4.5].

The following result has been shown in [10].

Theorem 13. A constraint language $\Gamma$ is tractable if and only if $\text{wRelClone}(\Gamma)$ is tractable, and $\Gamma$ is intractable if and only if $\text{wRelClone}(\Gamma)$ is intractable.

Consequently, when trying to identify tractable constraint languages, it is sufficient to consider only weighted relational clones.

2.3 Weighted clones

Any mapping $f : D^k \to D$ is called a $k$-ary operation. We will apply a $k$-ary operation $f$ to $k$ $m$-tuples $x_1, \ldots, x_k \in D^m$ coordinatewise, that is,

$$f(x_1, \ldots, x_k) = (f(x_1[1], \ldots, x_k[1]), \ldots, f(x_1[m], \ldots, x_k[m])) \in D^m.$$ (5)

Definition 14. Let $\gamma$ be an $m$-ary weighted relation on $D$ and let $f$ be a $k$-ary operation on $D$. Then $f$ is a polymorphism of $\gamma$ if, for any $(x_1, \ldots, x_k) \in (\text{Feas}(\gamma))^k$, we have $f(x_1, \ldots, x_k) \in \text{Feas}(\gamma)$.

For any constraint language $\Gamma$ over a set $D$, we denote by $\text{Pol}(\Gamma)$ the set of all operations on $D$ which are polymorphisms of all $\gamma \in \Gamma$. We write $\text{Pol}(\gamma)$ for $\text{Pol}(\{\gamma\})$.

A $k$-ary projection is an operation of the form $e_i^{(k)}(x_1, \ldots, x_k) = x_i$ for some $1 \leq i \leq k$. Projections are (trivial) polymorphisms of all constraint languages.

Definition 15. The superposition of a $k$-ary operation $f : D^k \to D$ with $k$ $\ell$-ary operations $g_i : D^\ell \to D$ for $1 \leq i \leq k$ is the $\ell$-ary function $f[g_1, \ldots, g_k] : D^\ell \to D$ defined by

$$f[g_1, \ldots, g_k](x_1, \ldots, x_\ell) = f(g_1(x_1, \ldots, x_\ell), \ldots, g_k(x_1, \ldots, x_\ell)).$$ (6)

Definition 16. A clone of operations, $C$, is a set of operations on $D$ that contains all projections and is closed under superposition. The $k$-ary operations in a clone $C$ will be denoted by $C^{(k)}$.

Example 17. For any $D$, let $J_D$ be the set of all projections on $D$. By Definition 16, $J_D$ is a clone.

It is well known that $\text{Pol}(\Gamma)$ is a clone for all constraint languages $\Gamma$.

Definition 18. A $k$-ary weighting of a clone $C$ is a function $\omega : C^{(k)} \to \mathbb{Q}$ such that $\omega(f) < 0$ only if $f$ is a projection and

$$\sum_{f \in C^{(k)}} \omega(f) = 0.$$ (7)

We will call a function $\omega : C^{(k)} \to \mathbb{Q}$ that satisfies Equation (7) but assigns a negative weight to some operation $f \notin J^{(k)}_D$ an improper weighting. In order to emphasise the distinction we may also call a weighting a proper weighting.

When specifying a weighting, we often write it as a weighted sum of operations (i.e. $\sum \omega(f) \cdot f$) without any zero terms.
Definition 19. For any clone \( C \), any \( k \)-ary weighting \( \omega \) of \( C \), and any \( g_1, \ldots, g_k \in C^{(k)} \), the superposition of \( \omega \) and \( g_1, \ldots, g_k \) is the function \( \omega[g_1, \ldots, g_k] : C^{(k)} \rightarrow \mathbb{Q} \) defined by
\[
\omega[g_1, \ldots, g_k](f') = \sum_{f \in C^{(k)} \land f[g_1, \ldots, g_k] = f'} \omega(f).
\]
By convention, the value of an empty sum is 0.

If the result of a superposition is a proper weighting (that is, negative weights are only assigned to projections), then that superposition will be called a proper superposition.

Definition 20. A weighted clone, \( \Omega \), is a non-empty set of weightings of some fixed clone \( C \), called the support clone of \( \Omega \), which is closed under scaling by non-negative rational constants, addition of weightings of equal arity, and proper superposition with operations from \( C \).

We now link weightings and weighted relations by the concept of weighted polymorphism, which will allow us to establish a correspondence between weighted clones and weighted relational clones.

Definition 21. Let \( \gamma \) be an \( m \)-ary weighted relation on \( D \) and let \( \omega \) be a \( k \)-ary weighting of a clone \( C \) of operations on \( D \). We call \( \omega \) a weighted polymorphism of \( \gamma \) if \( C \subseteq \text{Pol}(\gamma) \) and for any \((x_1, \ldots, x_k) \in (\text{Feas}(\gamma))^k\), we have
\[
\sum_{f \in C^{(k)}} \omega(f) \cdot \gamma(f(x_1, \ldots, x_k)) \leq 0.
\]
If \( \omega \) is a weighted polymorphism of \( \gamma \), we say that \( \gamma \) is improved by \( \omega \).

Example 22. Let \( D = \{0, 1\} \) with ordering \( 0 < 1 \). Binary operations min and max return the smaller and larger of their two arguments respectively. A function \( \gamma : D^k \rightarrow \mathbb{Q} \) is submodular if it satisfies \( \gamma(x_1) + \gamma(x_2) \geq \gamma(\min(x_1, x_2)) + \gamma(\max(x_1, x_2)) \) for all \( x_1, x_2 \). Clearly, submodular functions are improved by the binary weighting \( \omega = -e_1^{(2)} - e_2^{(2)} + \min + \max \).

Definition 23. For any \( \Gamma \subseteq \Phi_D \), we define \( \text{wPol}(\Gamma) \) to be the set of all weightings of \( \text{Pol}(\Gamma) \) which are weighted polymorphisms of all weighted relations \( \gamma \in \Gamma \). We write \( \text{wPol}(\gamma) \) for \( \text{wPol}(\{\gamma\}) \).

Definition 24. We denote by \( W_C \) the set of all possible (proper) weightings of clone \( C \), and define \( W_D \) to be the union of the sets \( W_C \) over all clones \( C \) on \( D \).

Any \( \Omega \subseteq W_D \) may contain weightings of different clones over \( D \). We can then extend each of these weightings with zeros, as necessary, so that they are weightings of the same clone \( C \), where \( C \) is the smallest clone containing all the clones associated with weightings in \( \Omega \).

Definition 25. We define \( \text{wClone}(\Omega) \) to be the smallest weighted clone containing this set of extended weightings obtained from \( \Omega \).

For any \( \Omega \subseteq W_D \), we denote by \( \text{Imp}(\Omega) \) the set of all weighted relations in \( \Phi_D \) which are improved by all weightings \( \omega \in \Omega \).

The main result in \([10]\) establishes a 1-to-1 correspondence between weighted relational clones and weighted clones.

Theorem 26 (\([10]\)).
1. For any finite \( D \) and any finite \( \Gamma \subseteq \Phi_D \), \( \text{Imp}(\text{wPol}(\Gamma)) = \text{wRelClone}(\Gamma) \).
2. For any finite \( D \) and any finite \( \Omega \subseteq W_D \), \( \text{wPol}(\text{Imp}(\Omega)) = \text{wClone}(\Omega) \).

Thus, when trying to identify tractable constraint languages, it is sufficient to consider only languages of the form \( \text{Imp}(\Omega) \) for some weighted clone \( \Omega \).
3 Results

First we show that Theorem 26 can be slightly extended to certain constraint languages and sets of weightings of infinite size.

Theorem 27.

1. Let $\Gamma \subseteq \Phi_D$. Then $\text{Imp}(\text{wPol}(\Gamma)) = \text{wRelClone}(\Gamma)$ if and only if $\text{wRelClone}(\Gamma) = \text{Imp}(\Omega)$ for some $\Omega \subseteq W_D$.

2. Let $\Omega \subseteq W_D$. Then $\text{wPol}(\text{Imp}(\Omega)) = \text{wClone}(\Omega)$ if and only if $\text{wClone}(\Omega) = \text{wPol}(\Gamma)$ for some $\Gamma \subseteq \Phi_D$.

Proof. We will only prove the first case as the second one is analogous.

Suppose that $\text{wRelClone}(\Gamma) = \text{Imp}(\Omega)$ for some $\Omega \subseteq W_D$. As $\Gamma \subseteq \text{wRelClone}(\Gamma)$, every weighting in $\Omega$ improves $\Gamma$, hence $\Omega \subseteq \text{wPol}(\Gamma)$ and $\text{Imp}(\text{wPol}(\Gamma)) \subseteq \text{Imp}(\Omega) = \text{wRelClone}(\Gamma)$. The inclusion $\text{wRelClone}(\Gamma) \subseteq \text{Imp}(\text{wPol}(\Gamma))$ follows from the fact that $\text{Imp}(\text{wPol}(\Gamma))$ is a weighted relational clone [10, Proposition 6.2] that contains $\Gamma$.

The converse implication holds trivially for $\Omega = \text{wPol}(\Gamma)$. \hfill \Box

We remark that any finitely generated weighted relational clone on a finite domain satisfies, by Theorem 26 (1), the condition of Theorem 27 (1). Similarly, any finitely generated weighted clone on a finite domain, by Theorem 26 (2), satisfies the condition of Theorem 27 (2).

However, our next result shows that Theorem 26 does not hold for all infinite constraint languages and infinite sets of weightings.

Theorem 28.

1. There is a finite $D$ and an infinite $\Gamma \subseteq \Phi_D$ with $\text{Imp}(\text{wPol}(\Gamma)) \neq \text{wRelClone}(\Gamma)$.

2. There is a finite $D$ and an infinite $\Omega \subseteq W_D$ with $\text{wPol}(\text{Imp}(\Omega)) \neq \text{wClone}(\Omega)$.

Our aim is to establish a Galois connection even for infinite sets of weighted relations and weightings. As we demonstrate in the proof of Theorem 28, this cannot be done when restricted to rational weights; hence we allow weighted relations and weightings to assign real-valued weights. To distinguish them from their formerly defined rational-valued counterparts, we will use a subscript/superscript $\mathbb{R}$.

We will show in Lemma 40 that $\text{wPol}_{\mathbb{R}}(\Gamma)$ is topologically closed (in a natural topology defined later) for any set of weighted relations $\Gamma$; analogously, in Lemma 41 we will show that $\text{Imp}_{\mathbb{R}}(\Omega)$ is topologically closed for any set of weightings $\Omega$. Therefore, our new definitions of weighted (relational) clones require them to be topologically closed.

Inspired by weighted pp-definitions [25], we extend the notion of weighted relational clones: we require them to be closed also under operator $\text{Opt}$. This change is justified by Theorem 44 in which we prove that the inclusion of $\text{Opt}$ preserves tractability. In order to retain the one-to-one correspondence with weighted clones, we need to alter their definition too: weightings now assign weights to all operations and hence are independent of the support clone (which becomes meaningless and we discard it).

Including the $\text{Opt}$ operator brings two advantages to the study of weighted clones. Firstly, it slightly simplifies the structure of the space of all weighted clones. According to the original
definition, a weighted clone is determined by its support clone and the set of weightings it consists of; by our definition a weighted clone equals the set of its weightings. Secondly, any non-projection polymorphism of a weighted relational clone \( \Gamma \) is assigned a positive weight by some weighted polymorphism of \( \Gamma \) (see Corollary 39).

Our main result is the following theorem, which holds for our new definition of real-valued weightings and weighted relations.

**Theorem 29 (Main).**

1. For any finite \( D \) and any \( \Gamma \subseteq \Phi_D \), \( \text{Imp}_\mathbb{R}(wPol_\mathbb{R}(\Gamma)) = wRelClone_\mathbb{R}(\Gamma) \).
2. For any finite \( D \) and any \( \Omega \subseteq W^\mathbb{R}_D \), \( wPol_\mathbb{R}(\text{Imp}_\mathbb{R}(\Omega)) = wClone_\mathbb{R}(\Omega) \).

Finally, we show that taking the weighted relational clone of a constraint language preserves solvability with an absolute error bounded by \( \epsilon \) (for any \( \epsilon > 0 \)), and demonstrate certain difficulties with proving that it preserves exact solvability.

### 4 Proof of Theorem 28

In this section we will prove Theorem 28, which we state here as two lemmas.

**Lemma 30.** There is a finite \( D \) and an infinite \( \Gamma \subseteq \Phi_D \) with \( \text{Imp}(wPol(\Gamma)) \neq wRelClone(\Gamma) \).

**Proof.** We set the domain to be \( D = \{0, 1, 2\} \) and choose a positive irrational number \( t \). Let \( U \subseteq \Phi_1(1) \) be the set of unary weighted relations \( \rho \) such that

\[
\rho(2) - \rho(0) \geq (1 + t) \cdot (\rho(1) - \rho(0)) \tag{10}
\]

holds whenever \( \rho(0), \rho(1), \rho(2) \) are all finite. It is easy to show that \( U \) is closed under addition, scaling by non-negative rational constants, and addition of rational constants.

For any rational \( u < t \), we define a unary weighted relation \( \mu_u^- \in U \) such that \( \mu_u^-(0) = 0 \), \( \mu_u^-(1) = -1 \), and \( \mu_u^-(2) = -1 - u \). For any rational \( v > t \), we define a unary weighted relation \( \mu_v^+ \in U \) such that \( \mu_v^+(0) = 0 \), \( \mu_v^+(1) = 1 \), and \( \mu_v^+(2) = 1 + v \). It is easy to verify that these weighted relations belong to \( U \). Set \( U \) also contains any unary (unweighted) relation.

Let us define \( \Gamma \subseteq \Phi_D \) as the set of weighted relations \( \gamma \) that can be written as

\[
\gamma(x_1, \ldots, x_r) = \sum_{i=1}^r \rho_i(x_i) + \sum_{(i,j) \in S} \phi_e(x_i, x_j), \tag{11}
\]

where \( r \) equals the arity of \( \gamma \), \( \rho_i \in U \) for all \( i \), \( \phi_e \) is the binary equality relation, and \( S \) is an equivalence relation on \( \{1, \ldots, r\} \). We claim that \( \Gamma \) is a weighted relational clone. It certainly contains \( \phi_e \) and \( \phi_\emptyset \), and is closed under addition, scaling by non-negative rational constants, and addition of rational constants (as set \( U \) is closed under these operations). It is also closed under minimisation. Without loss of generality, let us assume we minimise an \( r \)-ary weighted relation \( \gamma \) \((r \geq 2)\) over the last variable \( (x_r) \). If the equivalence class of \( r \) in \( S \) is a singleton, we simply add the value of \( \min_{x_r \in D} \rho_r(x_r) \) to (say) \( \rho_1 \). Otherwise, we can pick any \( i \neq r \) such that \((i, r) \in S\) and replace weighted relation \( \rho_i \) with \( \rho_i + \rho_r \).
We want to determine which weightings improve $\Gamma$. Let $\omega \in \text{wPol}^{(k)}(\Gamma)$ be a $k$-ary weighting and $x \in D^k$. For any $a \in D$, we will denote by $s_a$ the sum of weights $\omega(f)$ of all operations $f$ such that $f(x) = a$. Note that $s_0 + s_1 + s_2 = 0$. For any rational $v > t$, weighting $\omega$ improves $\mu_v^+ \in \Gamma$, so we get $s_1 + (1 + v) \cdot s_2 \leq 0$ and therefore $v \cdot s_2 \leq s_0$. Similarly, for any rational $u < t$, weighting $\omega$ improves $\mu_u^- \in \Gamma$, and therefore $s_0 \leq u \cdot s_2$. We can choose both $u$ and $v$ arbitrarily close to $t$, so it must hold $s_0 = t \cdot s_2$. However, $s_0$ and $s_2$ are rational while $t$ is not. Therefore, we must have $s_0 = s_1 = s_2 = 0$ for any weighting $\omega \in \text{wPol}^{(k)}(\Gamma)$ and any $x \in D^k$.

Now, let us consider the unary weighted relation $\rho$ defined as $\rho(0) = 0$ and $\rho(1) = \rho(2) = 1$. It follows from the previous paragraph that any weighting $\omega \in \text{wPol}(\Gamma)$ improves $\rho$, i.e. $\rho \in \text{Imp}(\text{wPol}(\Gamma))$. However, $\rho \notin \Gamma = \text{wRelClone}(\Gamma)$, so we get $\text{Imp}(\text{wPol}(\Gamma)) \neq \text{wRelClone}(\Gamma)$. \hfill \qed

**Lemma 31.** There is a finite $D$ and an infinite $\Omega \subseteq W_D$ with $\text{wPol}(\text{Imp}(\Omega)) \neq \text{wClone}(\Omega)$.

**Proof.** We set the domain to be $D = \{0, 1, 2\}$ and choose a positive irrational number $t$. Let $C$ be the set of all operations $f$ such that $f(0, \ldots, 0) = 0$. Clearly, $C$ contains all projections and is closed under superposition; hence it is a clone. Let us define a set of weightings $\Omega \subseteq W_D$ of the support clone $C$. For any arity $k \geq 1$, $\Omega^{(k)}$ consists of weightings $\omega$ such that for all $x \in D^k$,

$$t \cdot \sum_{f(x)=2} \omega(f) \leq \sum_{f(x)=0} \omega(f). \quad (12)$$

It is easy to check that $\Omega$ is closed under addition of weightings and non-negative scaling. To show that it is also closed under superposition, let us consider any sequence of $\ell$-ary operations $g_1, \ldots, g_k$ and $x \in D^\ell$. For any $a \in D$ we have

$$\sum_{f(x)=a} \omega[g_1, \ldots, g_k](f) = \sum_{f[g_1, \ldots, g_k](x)=a} \omega(f) = \sum_{f(y)=a} \omega(f), \quad (13)$$

where $y = (g_1(x), \ldots, g_k(x))$. As $\omega$ satisfies Inequality (12) for vector $y$, the superposition $\omega[g_1, \ldots, g_k]$ satisfies it for vector $x$. Therefore, $\Omega$ is a weighted clone.

Let us denote by $e_0$ the unary constant zero operation, by $f, g$ the unary operations and by $h$ the binary operation such that

$$f(x) = \begin{cases} 0 & \text{for } x = 0 \\ 0 & \text{for } x = 1 \\ 2 & \text{for } x = 2 \end{cases}, \quad g(x) = \begin{cases} 0 & \text{for } x = 0 \\ 2 & \text{for } x = 1 \\ 2 & \text{for } x = 2 \end{cases}, \quad h(x, y) = \begin{cases} 1 & \text{for } x = 0 \land y = 2 \\ 2 & \text{for } x = 2 \land y = 2 \\ 0 & \text{otherwise} \end{cases}. \quad (14)$$

We denote by $\omega_0$ the unary weighting $-e_1^{(1)} + c_0$. For any rational $v > t$, we define a unary weighting $\mu_v^{(1)} = -(1 + v) \cdot e_1^{(1)} + v \cdot f + g$. For any positive rational $u < t$, we define a binary weighting $\mu_u^{(2)} = -u \cdot e_1^{(2)} - e_2^{(2)} + (1 + u) \cdot h$. It is easy to show that all these weightings belong to $\Omega$.

We will show that all weighted relations improved by $\Omega$ are relations, i.e. $\text{Imp}(\Omega) \subseteq R_D$. Suppose, to the contrary, that there is an $r$-ary weighted relation $\gamma \in \text{Imp}(\Omega)$ that is not a relation. First, we obtain from it a ternary weighted relation with the same property. Weighting $\omega_0$ improves $\gamma$, so we have $\gamma(0) \leq \gamma(x)$ for all $x \in \text{Feas}(\gamma)$, where $0 = c_0(x)$ is the zero $r$-tuple. As $\gamma$ is not a relation, there must be an $r$-tuple $z = (z_1, \ldots, z_r) \in \text{Feas}(\gamma)$ for which $\gamma(0) < \gamma(z)$. Let us define a ternary weighted relation $\rho$ so that $\rho(x_0, x_1, x_2) = \gamma(x_{2z_1}, \ldots, x_{2z_r})$. It holds that $\rho(0, 0, 0) = \gamma(0)$ and $\rho(0, 1, 2) = \gamma(z)$, so $\rho(0, 0, 0) < \rho(0, 1, 2) < \infty$. Moreover, $\rho \in \text{Imp}(\Omega)$.
For any rational \( v > t \), weighting \( \mu_v^{(1)} \) improves \( \rho \). As \((0,1,2) \in \text{Feas}(\rho)\), we also have \((f(0),f(1),f(2)) = (0,0,2) \in \text{Feas}(\rho)\), \((g(0),g(1),g(2)) = (2,2) \in \text{Feas}(\rho)\), and the inequality

\[
\rho(0,2,2) - \rho(0,1,2) \leq v \cdot (\rho(0,1,2) - \rho(0,0,2)).
\]  

(15)

For any positive rational \( u < t \), weighting \( \mu_u^{(2)} \) improves \( \rho \). As \((0,0,2),(0,2,2) \in \text{Feas}(\rho)\), we get

\[
\rho(0,2,2) - \rho(0,1,2) \geq u \cdot (\rho(0,1,2) - \rho(0,0,2)).
\]  

(16)

We can choose both \( u \) and \( v \) arbitrarily close to \( t \), so it must hold

\[
\rho(0,2,2) - \rho(0,1,2) = t \cdot (\rho(0,1,2) - \rho(0,0,2)).
\]  

(17)

However, weights assigned by \( \rho \) are rational while \( t \) is not. Therefore, \( \rho(0,0,2) = \rho(0,1,2) = \rho(0,2,2) \). Similarly, by applying weightings \( \mu_u^{(2)} \) to \((0,0,0),(0,0,2) \) and weightings \( \mu_v^{(1)} \) to \((0,0,1) \) we obtain \( \rho(0,0,0) = \rho(0,0,1) = \rho(0,0,2) \), which contradicts \( \rho(0,0,0) < \rho(0,1,2) \). Therefore, \( \text{Imp}(\Omega) \) contains only (unweighted) relations.

Now, let us consider the unary weighting \( \omega = -e_1^{(1)} + g \). Although it does not belong to \( \Omega = \text{wClone}(\Omega) \) (it violates Inequality (12) for \( x = (1) \)), \( \omega \) certainly improves any \( \gamma \in \text{Imp}(\Omega) \). Therefore, \( \text{wPol}(\text{Imp}(\Omega)) \neq \text{wClone}(\Omega) \).

5 New Galois Connection

In this section we will prove our main results. In Section 5.1, we will describe the differences between the previous definitions of weighted (relational) clones (as they were defined in [10] and presented in Section 2 and the first part of Section 3) and our new definitions. Section 5.2 proves the main result, which establishes a 1-to-1 correspondence between weighted relational clones and weighted clones. Finally, Section 5.3 is devoted to computational-complexity consequences of our results.

5.1 Preliminaries

Let \( \mathbb{R} = \mathbb{R} \cup \{ \infty \} \) denote the set of real numbers with (positive) infinity. We will allow weights in relations and weighted relations, as defined in Definition 1 and 2 respectively, to be real numbers. In other words, an \( m \)-ary weighted relation \( \gamma \) on \( D \) is a mapping \( \gamma : D^m \to \mathbb{R} \). We will add a subscript/superscript \( \mathbb{R} \) to the notation introduced in Section 2 in order to emphasise the use of real weights.

For any fixed arity \( m \) and any \( F \subseteq D^m \), consider the set of all \( m \)-ary weighted relations \( \gamma \in \Phi^\mathbb{R}_D \) with \( \text{Feas}(\gamma) = F \). Let us denote this set by \( H \) and equip it with the inner product defined as

\[
\langle \alpha, \beta \rangle = \sum_{x \in F} \alpha(x) \cdot \beta(x)
\]  

(18)

for any \( \alpha, \beta \in H \); \( H \) is then a real Hilbert space. Set \( \Phi^\mathbb{R}_D \) is a disjoint union of such Hilbert spaces for all \( m \) and \( F \), and therefore a topological space with the disjoint union topology induced by inner products on the underlying Hilbert spaces. When we say a set of weighted relations is open/closed, we will be referring to this topology.
Definition 32. A constraint language $\Gamma \subseteq \Phi^R_D$ is called a weighted relational clone if it contains the binary equality relation $\phi_e$ and the unary empty relation $\phi_\emptyset$, is closed under addition, minimisation, scaling by non-negative real constants, addition of real constants, and operator Opt, and is topologically closed.

For any $\Gamma$, we define $w\text{RelClone}_R(\Gamma)$ to be the smallest weighted relational clone containing $\Gamma$.

As opposed to Definition 10, our new definition requires weighted relational clones to be closed under operator Opt. In order to establish a Galois connection now, we need to make an adjustment to the definition of weighted clone too. We will discard the explicit underlying support clone; instead, $(k\text{-ary})$ weightings will assign weights to all $(k\text{-ary})$ operations. The role of the support clone of a weighted clone $\Omega$ is then taken over by $\text{supp}(\Omega)$ (see Lemma 38).

We denote by $O^{(k)}_D$ the set of all $k\text{-ary}$ operations on $D$ and let $O_D = \bigcup_{k \geq 0} O^{(k)}_D$.

Definition 33. A $k\text{-ary}$ weighting is a function $\omega : O^{(k)}_D \to \mathbb{R}$ such that $\omega(f) < 0$ only if $f$ is a projection and

$$\sum_{f \in O^{(k)}_D} \omega(f) = 0.$$  \hfill (19)

We define $\text{supp}(\omega)$ as

$$\text{supp}(\omega) = J^{(k)}_D \cup \{ f \in O^{(k)}_D \mid \omega(f) > 0 \}.$$  \hfill (20)

We will call a function $\omega : O^{(k)}_D \to \mathbb{R}$ that satisfies Equation (19) but assigns a negative weight to some operation $f \notin J^{(k)}_D$ an improper weighting. In order to emphasise the distinction we may also call a weighting a proper weighting.

We denote by $W^R_D$ the set of all weightings on domain $D$. For any fixed arity $k$, consider the set $H$ of all functions $O^{(k)}_D \to \mathbb{R}$ equipped with the inner product defined as

$$\langle \alpha, \beta \rangle = \sum_{f \in O^{(k)}_D} \alpha(f) \cdot \beta(f)$$  \hfill (21)

for any $\alpha, \beta \in H$; $H$ is then a real Hilbert space. Set $W^R_D$ lies in the disjoint union of such Hilbert spaces for all $k$, which is a topological space with the disjoint union topology induced by inner products on the underlying Hilbert spaces. When we say a set of weightings is open/closed, we will be referring to this topology. Clearly, any closure point of a set of weightings is itself a weighting.

Definition 34. Let $\Omega$ be a non-empty set of weightings on a fixed domain $D$. We define $\text{supp}(\Omega) = J_D \cup \bigcup_{\omega \in \Omega} \text{supp}(\omega)$.

We call $\Omega$ a weighted clone if it is closed under scaling by non-negative real constants, addition of weightings of equal arity, and proper superposition with operations from $\text{supp}(\Omega)$, and is topologically closed.

It is often convenient to build a desired proper weighting by taking a sum of (possibly) improper superpositions. The following lemma, which is an analogue of [10, Lemma 6.4], shows that weighted clones are closed under such constructions.
Lemma 35. Let $\Omega$ be a weighted clone, $\omega_1, \ldots, \omega_n \in \Omega$, and $c_1, \ldots, c_n \geq 0$. We will denote the arity of weighting $\omega_i$ by $\ell_i$. For any $1 \leq i \leq n$ and $1 \leq j \leq \ell_i$, let $g_{i,j} \in \text{supp}(\Omega)$ be a $k$-ary operation (for some fixed arity $k$). If the $k$-ary weighting $\mu$ defined as

$$\mu = \sum_{i=1}^{n} c_i \cdot \omega_i[g_{i,1}, \ldots, g_{i,\ell_i}]$$

is proper, then $\mu \in \Omega$.

Proof. We show that weighting $\mu$ can be constructed using proper superpositions only.

Let us denote $\sum_{1 \leq i \leq n} \ell_i$ by $t$. For any $1 \leq m \leq n$, let $s_m = \sum_{1 \leq i < m} \ell_i$. A superposition with projections is always proper (as all negative weights are transferred to projections), and therefore the $t$-ary weighting $\mu'$ defined as

$$\mu' = \sum_{i=1}^{n} c_i \cdot \omega_i [e_{s_i+1}^{(t)}, \ldots, e_{s_i+t_i}^{(t)}]$$

belongs to $\Omega$. Since $\mu = \mu'[g_{1,1}, \ldots, g_{1,\ell_1}, g_{2,1}, \ldots, g_{n,\ell_n}]$, we get $\mu \in \Omega$. \qed

The following lemma has also been observed in [23, 30].

Lemma 36. Let $\Omega$ be a weighted clone. Then $\text{supp}(\Omega)$ is a clone.

Proof. We will denote $\text{supp}(\Omega)$ by $C$. Since it contains all projections, we only need to show that it is closed under superposition.

Let $f \in C^{(k)}$ and $g_1, \ldots, g_k \in C^{(t)}$. If $f[g_1, \ldots, g_k]$ is a projection or is equal to $g_i$ for some $i$, then it clearly belongs to $C$. Otherwise, $f$ is not a projection and therefore there is a $k$-ary weighting $\omega \in \Omega$ for which $\omega(f) > 0$. Weighting $\omega | g_1, \ldots, g_k$ certainly assigns a positive weight to $f[g_1, \ldots, g_k]$ (we are using the fact that only operations $g_1, \ldots, g_k$ may receive negative weight from projections in $\omega$). However, it is possibly improper, as it may assign a negative weight to some $g_i$ that is not a projection.

We denote by $G$ the set of such operations $g \in \{g_1, \ldots, g_k\}$ that are not projections and $\omega | g_1, \ldots, g_k(g) < 0$. For any $g \in G$, there is an $\ell$-ary weighting $\mu_g \in \Omega$ for which $\mu_g(g) > 0$. Then the $\ell$-ary weighting defined as

$$\omega | g_1, \ldots, g_k + \sum_{g \in G} \frac{-\omega | g_1, \ldots, g_k(g)}{\mu_g(g)} \cdot \mu_g$$

is proper, belongs to $\Omega$ (by Lemma 35), and assigns a positive weight to $f[g_1, \ldots, g_k]$. \qed

Again, we link weightings and weighted relations by the concept of weighted polymorphism.

Definition 37. Let $\gamma$ be an $m$-ary weighted relation on $D$ and let $\omega$ be a $k$-ary weighting on $D$. We call $\omega$ a weighted polymorphism of $\gamma$ if $\text{supp}(\omega) \subseteq \text{Pol}(\gamma)$ and for any $(x_1, \ldots, x_k) \in (\text{Feas}(\gamma))^k$, we have

$$\sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma(f(x_1, \ldots, x_k)) \leq 0.$$  

If $\omega$ is a weighted polymorphism of $\gamma$ we say that $\gamma$ is improved by $\omega$. We will denote the set of weighted polymorphisms of $\Gamma$ by $\text{wPol}_\mathbb{R}(\Gamma)$ and the set of weighted relations improved by $\Omega$ by $\text{Imp}_\mathbb{R}(\Omega)$. 

12
The next lemma shows that \( \text{supp}(\Omega) \) consists of all polymorphisms of \( \text{Imp}_R(\Omega) \) and hence fulfills the same role as the support clone in Definition 20.

**Lemma 38.** Let \( \Omega \subseteq \mathbf{W}^R_D \) be a weighted clone. Then \( \text{supp}(\Omega) = \text{Pol}(\text{Imp}_R(\Omega)) \).

**Proof.** We will denote \( \text{supp}(\Omega) \) by \( C \). Projections are polymorphisms of every weighted relation, and any operation \( f \) with \( \omega(f) > 0 \) for some \( \omega \in \Omega \) is a polymorphism of \( \text{Imp}_R(\Omega) \) by the definition of weighted polymorphism. Therefore, \( C \subseteq \text{Pol}(\text{Imp}_R(\Omega)) \).

Let \( \text{Inv}(C) \) be the set of (unweighted) relations over \( D \) that are invariant under all operations from \( C \) (i.e. operations from \( C \) are their polymorphisms). As any relation invariant under \( \text{supp}(\omega) \) is also improved by \( \omega \), we have \( \text{Inv}(C) \subseteq \text{Imp}_R(\Omega) \) and thus \( \text{Pol}(\text{Imp}_R(\Omega)) \subseteq \text{Pol}(\text{Inv}(C)) = C \) (the last equality follows from the Galois connection between relational clones and clones of operations [3, 14] and Lemma 36). \( \square \)

The following corollary has been observed in the context of Min-Sol-Hom and Min-Cost-Hom [31] by Hannes Uppman.\(^4\)

**Corollary 39.** Let \( \Gamma \subseteq \Phi^R_D \) be a weighted relational clone. Then \( \text{supp}(\text{wPol}_R(\Gamma)) = \text{Pol}(\Gamma) \).

**Proof.** We are going to use the Galois connection established later in Section 5.2.

As \( \text{wPol}_R(\Gamma) \) is a weighted clone (Lemma 40), by Lemma 38 we have \( \text{supp}(\text{wPol}_R(\Gamma)) = \text{Pol}(\text{Imp}_R(\text{wPol}_R(\Gamma))) = \text{Pol}(\Gamma) \) (the last equality follows from Theorem 42). \( \square \)

Finally, we introduce some notation that will be used throughout Section 5.2. A sequence of \( k \) \( m \)-tuples over \( D \) can be written as \( X = (x_1, \ldots, x_k) \in (D^m)^k \). By \( X^T \) we will denote the transpose of \( X \), i.e. the sequence of \( m \) \( k \)-tuples \( (y_1, \ldots, y_m) \in (D^k)^m \) such that \( y_i = (x_1[i], \ldots, x_k[i]) \). Let \( f \) be a \( k \)-ary operation; we denote by \( f(X) \) the \( m \)-tuple obtained by applying \( f \) coordinatewise to \( x_1, \ldots, x_k \), i.e. \( f(X) = f(x_1, \ldots, x_k) = (f(y_1), \ldots, f(y_m)) \).

Let \( \gamma \in \Phi^R_D \) be a weighted relation and \( \omega \in \mathbf{W}^R_D \) a \( k \)-ary weighting with \( \text{supp}(\omega) \subseteq \text{Pol}(\gamma) \). Let us denote by \( H \) the Hilbert space of functions \( \text{Pol}^{(k)}(\gamma) \rightarrow \mathbb{R} \) with the inner product analogous to (21). As weighting \( \omega \) assigns non-zero weights only to operations from \( \text{supp}(\omega) \subseteq \text{Pol}^{(k)}(\gamma) \), we can identify \( \omega \) with its restriction to \( \text{Pol}^{(k)}(\gamma) \). For any \( X \in (\text{Feas}(\gamma))^k \), we denote by \( \gamma[X] \) the vector in \( H \) such that \( \gamma[X](f) = \gamma(f(X)) \) for all \( f \in \text{Pol}^{(k)}(\gamma) \). Inequality (25) can be then written as \( \langle \omega, \gamma[X] \rangle \leq 0 \).

The (internal) polar cone \( K^\circ \) of a set \( K \subseteq H \) is defined as

\[
K^\circ = \left\{ \alpha \in H \mid \langle \alpha, \beta \rangle \leq 0 \text{ for all } \beta \in K \right\}.
\]  

It is well known ([4, 17]) that \( K^\circ \) is a convex cone, i.e. \( K^\circ \) is closed under addition of vectors and scaling by non-negative constants. Moreover, \( K^\circ \) is topologically closed, and \( K^{\circ \circ} = (K^\circ)^\circ \) is the closure of the smallest convex cone containing \( K \).\(^5\)

Let

\[
K = \left\{ \gamma[X] \mid X \in (\text{Feas}(\gamma))^k \right\}.
\]

Weighting \( \omega \) is then a weighted polymorphism of \( \gamma \) if and only if \( \omega \in K^\circ \).

\(^4\)Private communication, 2014.

\(^5\)If \( K \) is a finite set, the smallest convex cone containing \( K \) is topologically closed. This is why the former definitions of weighted (relational) clones did not have to require topological closedness explicitly.
5.2 Main Proofs

Lemma 40. For any finite \(D\) and any \(\Gamma \subseteq \Phi_D^R\), \(w\text{Pol}_R(\Gamma)\) is a weighted clone.

Proof. Let \(k \geq 1\) be a fixed arity. We denote by \(H\) the Hilbert space of functions \(\text{Pol}^{(k)}(\Gamma) \to \mathbb{R}\) and define a set \(K \subseteq H\) as

\[
K = \left\{ \gamma[X] \mid \gamma \in \Gamma \land X \in (\text{Feas}(\gamma))^k \right\}.
\]

A \(k\)-ary weighting \(\omega\) with \(\text{supp}(\omega) \subseteq \text{Pol}^{(k)}(\Gamma)\) is a weighted polymorphism of \(\Gamma\) if and only if its restriction to \(\text{Pol}^{(k)}(\Gamma)\) belongs to \(K^o\). Set \(w\text{Pol}_R^{(k)}(\Gamma)\) is therefore closed under addition as \(K^o\) is convex, it is closed under non-negative scaling as \(K^o\) is a cone, and it is topologically closed as \(K^o\) is.

It remains to show that \(w\text{Pol}_R(\Gamma)\) is closed under superposition. Let \(\omega \in w\text{Pol}_R(\Gamma)\) be a \(k\)-ary weighting and \(g_1, \ldots, g_k \in \text{Pol}(\Gamma)\) be \(\ell\)-ary operations. For any \(\gamma \in \Gamma\) and \(X \in (\text{Feas}(\gamma))^\ell\), we have \(Y = (g_1(X), \ldots, g_k(X)) \in (\text{Feas}(\gamma))^k\) and

\[
\sum_{f \in \text{supp}(\omega)} \omega[g_1, \ldots, g_k](f) \cdot \gamma(f(X)) = \sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma(f[g_1, \ldots, g_k](X)) = \sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma(f(Y)) \leq 0.
\]

Therefore, weighting \(\omega[g_1, \ldots, g_k]\) is a weighted polymorphism of \(\Gamma\). \(\square\)

Lemma 41. For any finite \(D\) and any \(\Omega \subseteq \text{W}^R_D\), \(\text{Imp}_R(\Omega)\) is a weighted relational clone.

Proof. Both \(\phi_{\omega}\) and \(\phi_{\emptyset}\) are improved by any weighting and hence belong to \(\text{Imp}_R(\Omega)\). Addition, non-negative scaling, and addition of a constant preserve Inequality (25), and therefore \(\text{Imp}_R(\Omega)\) is closed under these operations.

We need to prove that \(\text{Imp}_R(\Omega)\) is closed under minimisation. Let \(\gamma \in \text{Imp}_R(\Omega)\) be an \(r\)-ary weighted relation and consider \(\gamma'\) obtained from \(\gamma\) by minimising over the last argument, i.e.

\[
\gamma'(x_1, \ldots, x_{r-1}) = \min_{x_r \in D} \gamma(x_1, \ldots, x_{r-1}, x_r).
\]

Let \(\omega \in \Omega\) be a \(k\)-ary weighting and \(X' = (x'_1, \ldots, x'_k) \in (\text{Feas}(\gamma'))^k\). For any \(i \in \{1, \ldots, k\}\), we can extend \((r-1)\)-tuple \(x'_i\) to an \(r\)-tuple \(x_i \in \text{Feas}(\gamma)\) so that \(\gamma'(x'_i) = \gamma(x_i)\); we will denote the list of these extended \(r\)-tuples by \(X = (x_1, \ldots, x_k)\). Note that \(f(X)\) is an extension of \(f(X')\) for any \(k\)-ary operation \(f \in \text{supp}(\omega)\), and therefore \(\gamma'(f(X')) \leq \gamma(f(X))\). Moreover, \(\gamma'(f(X')) = \gamma(f(X))\) whenever \(f\) is a projection. As \(\gamma\) satisfies Inequality (25) and only projections may be assigned a negative weight, we have

\[
\sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma'(f(X')) \leq \sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma(f(X)) \leq 0,
\]

and thus \(\gamma' \in \text{Imp}_R(\Omega)\).

Now we prove that \(\text{Imp}_R(\Omega)\) is closed under operator \(\text{Opt}\). Let \(\gamma \in \text{Imp}_R(\Omega)\) and \(\rho = \text{Opt}(\gamma)\). We will assume that \(\text{Feas}(\gamma)\) is non-empty (otherwise \(\gamma = \rho\) and denote by \(c\) the minimum weight
assigned by $\gamma$. Let $\omega \in \Omega$ be a $k$-ary weighting. As $\rho$ is a relation, we only need to show that all operations in the support of $\omega$ are polymorphisms of $\rho$. Let $X \in (\text{Feas}(\rho))^k \subseteq (\text{Feas}(\gamma))^k$. For any operation $f$ in the support of $\omega$, it holds $\gamma(f(X)) \geq c$. Moreover, $\gamma(f(X)) = c$ whenever $f$ is a projection. We have

$$0 \geq \sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma(f(X)) \geq \sum_{f \in \text{supp}(\omega)} \omega(f) \cdot c = 0,$$

which for all $f \in \text{supp}(\omega)$ implies $\gamma(f(X)) = c$ and hence $f(X) \in \text{Feas}(\rho)$. Therefore, $\rho \in \text{Imp}_\mathcal{R}(\Omega)$.

Finally, we show that $\text{Imp}_\mathcal{R}(\Omega)$ is topologically closed. Let $r$ be a fixed arity and $F \subseteq D^r$; we claim that the set $\Gamma \subseteq \Phi^\mathcal{R}_D$ of $r$-ary weighted relations $\gamma$ with $\text{Feas}(\gamma) = F$ which are not improved by $\Omega$ is an open set. Take any $\gamma \in \Gamma$. There must be a non-zero weighting $\omega \in \Omega$ (let us denote its arity by $k$) and $X \in F^k$ such that $\langle \omega, \gamma[X] \rangle = d$ for some positive $d$, i.e. $\omega$ violates Inequality (25) for $\gamma$ and $X$. Then for every $r$-ary weighted relation $\gamma'$ with $\text{Feas}(\gamma') = F$ and distance from $\gamma$ less than

$$\frac{d}{\sum_{f \in \text{supp}(\omega)} |\omega(f)|}$$

it holds $\langle \omega, \gamma'[X] \rangle > 0$, so $\gamma$ has a neighbourhood contained in $\Gamma$.

We are now ready to prove our main result, stated as Theorems 42 and 43.

**Theorem 42.** For any finite $D$ and any $\Gamma \subseteq \Phi^\mathcal{R}_D$, $\text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma)) = \text{wRelClone}_\mathcal{R}(\Gamma)$.

**Proof.** First, we show that $\text{wRelClone}_\mathcal{R}(\Gamma) \subseteq \text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma))$. Surely $\Gamma \subseteq \text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma))$ and therefore $\text{wRelClone}_\mathcal{R}(\Gamma) \subseteq \text{wRelClone}_\mathcal{R}(\text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma)))$. By Lemma 41 we know that $\text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma))$ is a weighted relational clone. Hence, $\text{wRelClone}_\mathcal{R}(\text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma))) = \text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma))$.

Now we will prove the other inclusion, $\text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma)) \subseteq \text{wRelClone}_\mathcal{R}(\Gamma)$. Let $\rho \in \text{Imp}_\mathcal{R}(\text{wPol}_\mathcal{R}(\Gamma))$ be a weighted relation and denote $|\text{Feas}(\rho)|$ by $k$. If $k = 0$, $\rho$ is expressible from $\phi_0$ and hence $\rho \in \text{wRelClone}_\mathcal{R}(\Gamma)$. Otherwise, we will focus solely on the $k$-ary weighted polymorphisms of $\Gamma$. Let us denote the Hilbert space of functions $\text{Pol}^{(k)}(\Gamma) \rightarrow \mathbb{R}$ by $H$; the $k$-ary weighted polymorphisms of $\Gamma$ can be then seen as vectors from $H$. Denoting $m = |D|^k$, a $k$-ary operation on $D$ is uniquely determined by the $m$-tuple of labels it assigns to its $m$ possible inputs. Later we will define a correspondence between a subset of $m$-ary weighted relations and $H$.

The outline of the proof is as follows. We transform $\Gamma$ into a set $M \subseteq \text{wRelClone}_\mathcal{R}(\Gamma)$ of $m$-ary weighted relations and consider their corresponding vectors in $H$. The polar cone of these vectors equals $\text{wPol}^{(k)}_\mathcal{R}(\Gamma)$, and its polar cone, in turn, consists of $m$-ary weighted relations improved by $\text{wPol}^{(k)}_\mathcal{R}(\Gamma)$. We know that the polar cone of the polar cone of a set is the closure of the smallest convex cone containing this set; therefore, any $m$-ary weighted relation improved by $\text{wPol}^{(k)}_\mathcal{R}(\Gamma)$ belongs to $\text{wRelClone}_\mathcal{R}(\Gamma)$. This also includes a particular $m$-ary weighted relation that we use to express $\rho$, so we get $\rho \in \text{wRelClone}_\mathcal{R}(\Gamma)$.

We begin by formally defining the correspondence between certain $m$-ary weighted relations and vectors from $H$. Let us denote by $(z_1, \ldots, z_m) = Z^T$ the sequence of all $k$-tuples over $D$ in an arbitrary fixed order; any $k$-ary operation $f$ is then determined by the $m$-tuple $(f(z_1), \ldots, f(z_m)) = f(Z)$. Let us define a set $F \subseteq D^m$ as

$$F = \left\{ f(Z) \mid f \in \text{Pol}^{(k)}(\Gamma) \right\}.$$  

(36)
For any \( m \)-ary weighted relation \( \gamma \) with \( \text{Feas}(\gamma) = F \), the corresponding vector in \( H \) is \( \gamma[Z] \). Conversely, for any vector in \( H \) there is a corresponding \( m \)-ary weighted relation with finite weights precisely on \( F \).

Now we transform \( \Gamma \) into a set of \( m \)-ary weighted relations \( M \subseteq w\text{RelClone}_R(\Gamma) \) that captures enough information to reconstruct the set of \( k \)-ary weighted polymorphisms of \( \Gamma \). Let \( \gamma \in \Gamma \) be an \( n \)-ary weighted relation and \( X \in (\text{Feas}(\gamma))^k \); we will denote the \( k \)-tuples of \( X^T \) by \((x_1, \ldots, x_n)\). We claim that there is an \( m \)-ary weighted relation \( \mu_{\gamma,X} \in w\text{RelClone}_R(\Gamma) \) with \( \text{Feas}(\mu_{\gamma,X}) = F \) such that \( \mu_{\gamma,X}(f(Z)) = \gamma(f(X)) \) for all \( f \in \text{Pol}^{(k)}(\Gamma) \). First, we construct an \( m \)-ary weighted relation \( \mu'_{\gamma,X} \) as

\[
\mu'_{\gamma,X}(y_{z_1}, \ldots, y_{z_m}) = \gamma(y_{x_1}, \ldots, y_{x_n}),
\]

where \( y_{z_i} \) are variables indexed by \( k \)-tuples over \( D \). Clearly, \( \mu'_{\gamma,X}(f(Z)) = \mu'_{\gamma,X}(f(z_1), \ldots, f(z_m)) = \gamma(f(x_1), \ldots, f(x_n)) = \gamma(f(X)) \). However, we are not done yet, as \( \mu'_{\gamma,X} \) assigns a finite weight to all \( m \)-tuples \( f(Z) \) such that \( f(X) \in \text{Feas}(\gamma) \), even if \( f \not\in \text{Pol}^{(k)}(\Gamma) \). We can easily fix this: Let \( f \) be an \( k \)-ary operation that is not a polymorphism of \( \Gamma \); then there is a weighted relation \( \gamma_f \in \Gamma \) and \( X_f \in (\text{Feas}(\gamma_f))^k \) such that \( f(X_f) \not\in \text{Feas}(\gamma_f) \). Adding \( 0 \cdot \mu'_{\gamma_f,X_f} \) to \( \mu'_{\gamma,X} \) ensures that the weighted relation will assign infinity to \( m \)-tuple \( f(Z) \) without changing other weights. This can be done for all (finitely many) such operations \( f \), so we obtain a weighted relation \( \mu_{\gamma,X} \) with \( \text{Feas}(\mu_{\gamma,X}) = F \).

Similarly, there are \( m \)-ary weighted relations \( \mu_i, \mu_{-i} \in w\text{RelClone}_R(\Gamma) \) with \( \text{Feas}(\mu_i) = \text{Feas}(\mu_{-i}) = F \) such that \( \mu_i(f(Z)) = 1 \) and \( \mu_{-i}(f(Z)) = -1 \) for all \( f \in \text{Pol}^{(k)}(\Gamma) \). Again, we start with \( \mu'_i(y_{z_1}, \ldots, y_{z_m}) = 1 \), \( \mu'_{-i}(y_{z_1}, \ldots, y_{z_m}) = -1 \) and then add \( 0 \cdot \mu'_{\gamma_f,X_f} \) for all \( k \)-ary operations \( f \not\in \text{Pol}^{(k)}(\Gamma) \) to ensure that the resulting weighted relations \( \mu_i, \mu_{-i} \) assign finite weights only to \( m \)-tuples from \( F \).

Let \( i \in H \) be the vector assigning every operation value \( 1 \). For any operation \( f \in \text{Pol}^{(k)}(\Gamma) \) that is not a projection, let \( \chi_f \in H \) be the vector such that \( \chi_f(f) = 1 \) and \( \chi_f(g) = 0 \) for all \( g \neq f \). We define a set of \( m \)-ary weighted relations \( M \subseteq w\text{RelClone}_R(\Gamma) \), the set of corresponding vectors \( V \subseteq H \), and an auxiliary set of vectors \( W \subseteq H \) as follows:

\[
\begin{align*}
M &= \{ \mu_{\gamma,X} \mid \gamma \in \Gamma \land X \in (\text{Feas}(\gamma))^k \} \cup \{ \mu_i, \mu_{-i} \} \\
V &= \{ \gamma[X] \mid \gamma \in \Gamma \land X \in (\text{Feas}(\gamma))^k \} \cup \{ \iota, -\iota \} \\
W &= V \cup \left\{ -\chi_f \mid f \in \text{Pol}^{(k)}(\Gamma) \setminus J_D^{(k)} \right\}.
\end{align*}
\]

We claim that the polar cone \( W^0 \) consists of \( k \)-ary weighted polymorphisms of \( \Gamma \). Let \( \omega \in W^0 \) be a vector. As \( \langle \omega, \iota \rangle \leq 0 \) and \( \langle \omega, -\iota \rangle \leq 0 \), we have \( \langle \omega, \iota \rangle = 0 \), i.e. the sum of weights of \( \omega \) equals 0. For any non-projection \( f \) we have \( \langle \omega, -\chi_f \rangle \leq 0 \), i.e. \( \omega(f) \) is non-negative. Finally, for any \( \gamma \in \Gamma \) and \( X \in (\text{Feas}(\gamma))^k \) it holds \( \langle \omega, \gamma[X] \rangle \leq 0 \); hence \( \omega \) is a weighted polymorphism of \( \Gamma \).

Let us now return to weighted relation \( \rho \) and denote the sequence of elements of \( \text{Feas}(\rho) \) in an arbitrary fixed order by \( R \in (\text{Feas}(\rho))^k \). As \( \rho \) is improved by \( w\text{Pol}_R(\Gamma) \), any vector \( \omega \in W^0 \) satisfies Inequality (25) for \( \rho \) and any \( X \in (\text{Feas}(\rho))^k \), in particular for \( X = R \). Hence, we would like to claim that \( \langle \omega, \rho[R] \rangle \leq 0 \) for all \( \omega \in W^0 \) and thus \( \rho[R] \in W^{\infty} \). However, \( \rho[R] \) might be ill-defined: Although \( \rho \in \text{Imp}_R(w\text{Pol}_R(\Gamma)) \), not necessarily all operations \( f \in \text{Pol}^{(k)}(\Gamma) \) are polymorphisms of \( \rho \), and therefore possibly \( \rho(f(R)) = \infty \). Let us denote the set of these problematic operations by

\[
Q = \left\{ f \in \text{Pol}^{(k)}(\Gamma) \mid f(R) \not\in \text{Feas}(\rho) \right\}.
\]
On the other hand, every operation in the support of \( w\text{Pol}_{\mathbb{R}}(\Gamma) \) is a polymorphism of \( \rho \). This implies that operations in \( Q \) must be assigned a zero weight by all \( \omega \in W^o \). As \( \rho[R] \) might not exist, let us define instead a substitute vector \( \beta \in H \) such that \( \beta(f) = \rho(f(R)) \) for all \( f \in \text{Pol}(\Gamma) \setminus Q \), with arbitrary values assigned to operations in \( Q \). By the previous argument, \( \beta \in W^o \). Additionally, let \( \beta_0 \in H \) be a vector such that \( \beta_0(f) > 0 \) if \( f \in Q \), and \( \beta_0(f) = 0 \) otherwise. For any \( \omega \in W^o \) it holds \( \langle \omega, \beta_0 \rangle = 0 \), so \( \beta_0 \) also belongs to \( W^o \).

Any vector in \( W^o \) can be obtained from some vector in \( V^o \) by adding non-negative multiples of \( -\chi_f \) for \( f \in \text{Pol}(\Gamma) \setminus J \). Therefore, there is a vector \( \alpha \in V^o \) such that \( \alpha(f) \geq \beta(f) = \rho(f(R)) \) for all \( f \notin Q \), and \( \alpha(f) = \beta(f) = \rho(f(R)) \) when \( f \) is a projection. Also, there is a non-negative vector \( \alpha_0 \in V^o \) such that \( \alpha_0(f) > 0 \) if \( f \in Q \), and \( \alpha_0(f) = \beta_0(f) = 0 \) if \( f \) is a projection.

Vectors in \( V \) correspond to weighted relations in \( M \subseteq w\text{Rel}_{\mathbb{R}}(\Gamma) \). Set \( V^o \) is the closure of the smallest convex cone containing \( V \), and therefore weighted relations corresponding to vectors in \( V^o \) also belong to \( w\text{Rel}_{\mathbb{R}}(\Gamma) \) (as it is closed under addition and non-negative scaling, and is topologically closed). Hence, there are \( m \)-ary weighted relations \( \psi, \psi_0 \in w\text{Rel}_{\mathbb{R}}(\Gamma) \) with \( \text{Feas}(\psi) = \text{Feas}(\psi_0) = F \) such that \( \psi[Z] = \alpha \) and \( \psi_0[Z] = \alpha_0 \). We are going to express \( \rho \) from them.

Let us denote the arity of \( \rho \) by \( n \) and the \( k \)-tuples of \( R^T \) by \( (r_1, \ldots, r_n) \). Consider the following gadget. Let \( I \) be a VCSP instance with variables \( y_{z_1}, \ldots, y_{z_m} \) and a single constraint \( \psi(y_{z_1}, \ldots, y_{z_m}) \), and let \( L = (y_{r_1}, \ldots, y_{r_n}) \). Then \( \pi_L(I) \) is an \( n \)-ary weighted relation expressible over \( w\text{Rel}_{\mathbb{R}}(\Gamma) \); we will denote it by \( \rho' \). For any \( n \)-tuple \( x \in D^n \), we have

\[
\rho'(x) = \min_{\{ y_{z_1}, \ldots, y_{z_m} \} \in D^m \mid (y_{r_1}, \ldots, y_{r_n}) = x} \psi(y_{z_1}, \ldots, y_{z_m}) \tag{42}
\]

\[
= \min_{\{ f : D^k \to D \mid (f(r_1), \ldots, f(n)) = x \}} \psi(f(z_1), \ldots, f(z_m)) \tag{43}
\]

\[
= \min_{f(R) = x} \psi(f(Z)) = \min_{f(R) = x} \alpha(f). \tag{44}
\]

Analogously, by replacing \( \psi \) with \( \psi_0 \) in the gadget we obtain an \( n \)-ary weighted relation \( \rho'_0 \) for which \( \rho'_0(x) = \min_{f(R) = x} \alpha_0(f) \).

For any \( x \in \text{Feas}(\rho) \) and \( k \)-ary operation \( f \) such that \( f(R) = x \), it holds \( \alpha(f) \geq \rho(f(R)) = \rho(x) \). As \( R \) is a list of all elements of \( \text{Feas}(\rho) \), there is a projection \( f \) such that \( f(R) = x \); for it we have \( \alpha(f) = \rho(f(R)) = \rho(x) \). Therefore, \( \rho'(x) = \rho(x) \). Similarly we get \( \rho'_0(x) = 0 \) for any \( x \in \text{Feas}(\rho) \).

We are almost done; the last issue is that \( \rho'(x) \) may be finite also for some \( x \notin \text{Feas}(\rho) \). But \( f(R) \notin \text{Feas}(\rho) \) implies \( f \notin Q \), and in that case \( \alpha(f) = \rho(x) \). Therefore, \( \text{Opt}(\rho'_0) \) is finite only on \( \text{Feas}(\rho) \), and \( \rho' + \text{Opt}(\rho'_0) = \rho \).

**Theorem 43.** For any finite \( D \) and any \( \Omega \subseteq W^\mathbb{R}_D \), \( \text{wPol}_{\mathbb{R}}(\text{Imp}_R(\Omega)) = \text{wClone}_{\mathbb{R}}(\Omega) \).

**Proof.** We begin with the inclusion \( \text{wClone}_{\mathbb{R}}(\Omega) \subseteq \text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega)) \).

Weightings in \( \Omega \) are weighted polymorphisms of all weighted relations in \( \text{Imp}_{\mathbb{R}}(\Omega) \), so \( \Omega \subseteq \text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega)) \), and hence \( \text{wClone}_{\mathbb{R}}(\Omega) \subseteq \text{wClone}_{\mathbb{R}}(\text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega))) \). By Lemma 40, we have that \( \text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega)) \) is a weighted clone, so \( \text{wClone}_{\mathbb{R}}(\text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega))) = \text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega)) \).

Now we prove that for any \( k \geq 1 \) and any \( k \)-ary weighting \( \mu \in \text{wPol}_{\mathbb{R}}(\text{Imp}_{\mathbb{R}}(\Omega)) \), it holds \( \mu \in \text{wClone}_{\mathbb{R}}(\Omega) \). First, let us establish the clone of operations we will be working with. Let \( C \) be the smallest clone containing \( \text{supp}(\Omega) \). The support of \( \text{wClone}_{\mathbb{R}}(\Omega) \) is itself a clone (by Lemma 36) so we also have \( C = \text{supp}(\text{wClone}_{\mathbb{R}}(\Omega)) \). As in the proof of Theorem 42, we will represent \( k \)-ary
weightings by vectors of the Hilbert space \( H = C^{(k)} \to \mathbb{R} \), and identify those vectors with certain \( m \)-ary weighted relations (where \( m = |D|^k \)).

The outline of the proof is as follows. We transform \( \Omega \) into a set \( W \) of \( k \)-ary weightings. Although some of these weightings may be improper, any proper weighting obtained as their non-negative linear combination belongs to \( \text{wClone}_\mathbb{R}(\Omega) \). The polar cone \( W^\circ \) consists of \( m \)-ary weighted relations improved by \( \Omega \), and its polar cone \( W^{\circ\circ} \) hence contains \( \mu \). As the polar cone of the polar cone of a set is the closure of the smallest convex cone containing this set, we get \( \mu \in \text{wClone}_\mathbb{R}(\Omega) \).

Recall the correspondence between a subset of \( m \)-ary weighted relations and \( H \) from the proof of Theorem 42. This time, we are working with clone \( C \), so we define \( F \) as

\[
F = \left\{ f(Z) \mid f \in C^{(k)} \right\}.
\]  

Let \( \Gamma \) be the set of all \( m \)-ary weighted relations \( \gamma \) with \( \text{Feas}(\gamma) = F \). Similarly as before, there is a bijection between \( \Gamma \) and \( H \): the corresponding vector to a weighted relation \( \gamma \in \Gamma \) is \( \gamma[Z] \).

We show that \( k \)-ary polymorphisms of any \( \gamma \in \Gamma \) are precisely the operations from \( C^{(k)} \). Let \( f \in C^{(k)} \). For any \( X \in F^k \), there are \( k \)-ary operations \( g_1, \ldots, g_k \in C^{(k)} \) such that \( X = (g_1(Z), \ldots, g_k(Z)) \). So we have \( f(X) = f[g_1, \ldots, g_k](Z) \in F \) because \( f[g_1, \ldots, g_k] \in C^{(k)} \). Conversely, let \( f \) be a \( k \)-ary operation not belonging to \( C^{(k)} \). Certainly \( Z = (e_1^k(Z), \ldots, e_k^k(Z)) \in F^k \), but \( f(Z) \notin F \). Therefore, \( f \) is not a polymorphism of \( \gamma \).

Let us define a set \( W \subseteq H \) as

\[
W = \left\{ \omega[g_1, \ldots, g_\ell] \in H \mid \ell \geq 1 \land \omega \in \Omega^{(\ell)} \land g_1, \ldots, g_\ell \in C^{(k)} \right\}.
\]  

We claim that for any vector in the polar cone \( W^\circ \), the corresponding weighted relation is improved by \( \Omega \). Let \( \gamma \in \Gamma \) be a weighted relation such that \( \gamma[Z] \in W^\circ \), \( \omega \in \Omega \) be an \( \ell \)-ary weighting, and \( X \in F^\ell \). Then there are \( k \)-ary operations \( g_1, \ldots, g_\ell \in C^{(k)} \) for which \( X = (g_1(Z), \ldots, g_\ell(Z)) \), and we have

\[
\sum_{f \in \text{supp}(\omega)} \omega(f) \cdot \gamma(f(X)) = \sum_{f \in C^{(\ell)}} \omega(f) \cdot \gamma(f[g_1, \ldots, g_\ell](Z)) = \sum_{f \in C^{(k)}} \omega[g_1, \ldots, g_\ell](f) \cdot \gamma(f(Z)) = \langle \omega[g_1, \ldots, g_\ell], \gamma[Z] \rangle \leq 0.
\]  

Weighting \( \mu \) is a weighted polymorphism of \( \text{Imp}_\mathbb{R}(\Omega) \), so it improves any weighted relation \( \gamma \) corresponding to a vector in \( W^\circ \). Firstly, this implies \( \text{supp}(\mu) \subseteq C^{(k)} \); we can therefore view \( \mu \) as a vector of \( H \). Secondly, \( \mu \) satisfies Inequality (25) for \( \gamma \) and any \( X \in F^k \). In particular, \( Z \in F^k \), so we get \( \langle \mu, \gamma[Z] \rangle \leq 0 \) and thus \( \mu \in W^{\circ\circ} \).

Set \( W^{\circ\circ} \) is the closure of the smallest convex cone containing \( W \). By Lemma 35, any proper weighting obtained as a non-negative linear combination of weightings from \( W \) belongs to \( \text{wClone}_\mathbb{R}(\Omega) \). Therefore, \( \mu \in \text{wClone}_\mathbb{R}(\Omega) \).

### 5.3 Complexity Consequences

When studying the computational complexity of constraint languages, the focus on weighted relational clones is justified by Theorem 13. The aim of this section is to discuss the consequences
of our changes in the definition of weighted relational clones (allowing real weights and requiring weighted relational clones to be closed under operator Opt and to be topologically closed) on the validity of that theorem. We will assume the arithmetic model of computation, i.e. basic arithmetic operations with real numbers take a constant time.

First we show that adding operator Opt preserves the tractability of weighted relational clones.

**Theorem 44.** Let $\Gamma \subseteq \Phi_D^w$ be a finite constraint language and $\gamma \in \Gamma$. Then $\text{VCSP}(\Gamma \cup \{\text{Opt}(\gamma)\})$ polynomial-time reduces to $\text{VCSP}(\Gamma)$.

**Proof.** Adding a constant to all weights of a weighted relation changes the value of every assignment by the same amount, and hence does not affect tractability. Without loss of generality, we may therefore assume that all weighted relations in $\Gamma$ assign non-negative weights and that the minimum weight assigned by $\gamma$ equals 0. We will also assume that $\gamma$ is not a relation, otherwise $\text{Opt}(\gamma) = \gamma$ so the claim would hold trivially. Let us denote by $m$ the smallest positive weight assigned by $\gamma$, and by $M$ the largest finite weight assigned by any $\gamma' \in \Gamma$.

Let $I \in \text{VCSP}(\Gamma \cup \{\text{Opt}(\gamma)\})$ be an instance with $q$ constraints. We replace every constraint of the form $\text{Opt}(\gamma)(x)$ in $I$ with $(q\cdot \lceil M/m \rceil + 1)$ copies of $\gamma(x)$, thus obtaining a polynomially larger instance $I' \in \text{VCSP}(\Gamma)$. Any feasible assignment for instance $I$ is also feasible for $I'$ with the same value, which does not exceed $qM$. On the other hand, any infeasible assignment for instance $I$ is infeasible for $I'$, or it incurs an infinite value from a constraint of the form $\text{Opt}(\gamma)(x)$ in $I$ and therefore a value of more than $qM$ in $I'$.

For any constraint language $\Gamma \subseteq \Phi_D^w$, we will denote by $\Gamma_\sim$ the smallest set of weighted relations containing $\Gamma$ that is closed under scaling by non-negative real constants and addition of real constants. Analogously to [10, Theorem 4.3], we would like to show that $\Gamma$ is tractable if and only if $\Gamma_\sim$ is tractable. Their proof, however, does not apply to scaling by an irrational factor $\alpha$, as it relies on the existence of integers $p,q$ such that $\alpha = p/q$. In fact, we were not able to prove that real-valued scaling preserves tractability when insisting on exact solvability. If we consider solving VCSP with an absolute error bounded by $\epsilon$ (for any $\epsilon > 0$), then real-valued scaling does preserve tractability, as shown in the following theorem.

**Theorem 45.** Let $\Gamma, \Gamma' \subseteq \Phi_D^w$ be finite constraint languages such that $\Gamma$ contains only weighted relations of the form $c \cdot \gamma'$ for $c \geq 0, \gamma' \in \Gamma'$. For any $\epsilon > 0$, there is a polynomial-time reduction that for any instance $I \in \text{VCSP}(\Gamma)$ outputs an instance $I' \in \text{VCSP}(\Gamma')$ such that for any optimal assignment $s'$ of $I'$ it holds $I(s') \in [v,v+\epsilon]$, where $v$ is the value of an optimal assignment of $I$.

**Proof.** Again, we may assume that all weighted relations in $\Gamma$ and $\Gamma'$ assign non-negative weights. Let us denote by $M$ the largest finite weight assigned by any weighted relation in $\Gamma'$; we may assume that $M$ is well-defined and positive, otherwise we would have $\Gamma \subseteq \Gamma'$. We will denote by $q$ the number of constraints in $I$ and let $b = \lceil qM/\epsilon \rceil$.

Let instance $I' \in \text{VCSP}(\Gamma')$ have the same set of variables as $I$. For any constraint $c_i \cdot \gamma'_i(x_i)$ of $I$, we add $(\lceil bc_i \rceil + 1)$ copies of constraint $\gamma'_i(x_i)$ into $I'$. Note that any feasible assignment of $I$ is a feasible assignment of $I'$, and vice versa. Let us assume that $I$ admits a feasible solution. As $(\lceil bc_i \rceil + 1) - bc_i \in (0,1]$, we have

$$b \cdot I(t) \leq I'(t) \leq b \cdot I(t) + qM \tag{50}$$

for any feasible assignment $t$. Let $s$ be an optimal assignment of $I$; we get

$$b \cdot I(s') \leq I'(s') \leq b \cdot I(s) + qM \tag{51}$$
and therefore $I(s') \leq I(s) + \epsilon = v + \epsilon$.

Taking a topological closure of a language also preserves tractability with a bounded absolute error, as the following theorem shows.

**Theorem 46.** Let $\Gamma \subseteq \Phi^D$ be a constraint language and denote by $\overline{\Gamma}$ its closure. For any $\epsilon > 0$, there is a polynomial-time reduction that for any instance $I \in \text{VCSP}(\overline{\Gamma})$ outputs an instance $I' \in \text{VCSP}(\Gamma)$ with the same variables such that any assignment $t$ is either infeasible for both $I$ and $I'$, or is feasible for both and $|I(t) - I'(t)| \leq \epsilon$.

**Proof.** Let us denote by $q$ the number of constraints in $I$. For any $\gamma \in \Gamma$, there is a weighted relation $\gamma' \in \Gamma$ of the same arity and with $\text{Feas}(\gamma) = \text{Feas}(\gamma')$ such that the distance between $\gamma$ and $\gamma'$ is at most $\epsilon/q$. We obtain the sought instance $I'$ by replacing all constraints $\gamma$ from $I$ with their counterparts $\gamma'$.

We finish this section with a discussion of the difficulty of improving Theorem 45 to exact solvability (to optimality). Let $\Gamma$ be a finite constraint language and $\gamma \in \Gamma$. We would like to prove that $\text{VCSP}(\Gamma \cup \{c \cdot \gamma\})$ polynomial-time reduces to $\text{VCSP}(\Gamma)$, where $c \in \mathbb{R}_{\geq 0}$. Given $I \in \text{VCSP}(\Gamma \cup \{c \cdot \gamma\})$, let

$$\delta_I = \min \left\{ |I(s_1) - I(s_2)| \mid s_1, s_2 \text{ are solutions to } I \text{ with different values} \right\}. \quad (52)$$

If we choose an $\epsilon < \delta_I$, we obtain an optimal solution of $I$ by Theorem 45. However, it is not clear how fast the value of $\delta_I$ approaches 0 as the size of $I$ grows to infinity, and whether it is possible to compute it in polynomial time.
