**How to cite this article:** Hamid S, Bhat MA, Mir IA, Taku A, Badroo GA, Nazki S, Malik A (2017) Phenotypic and genotypic characterization of methicillin-resistant *Staphylococcus aureus* from bovine mastitis, *Veterinary World*, 10(3): 363-367.

**Abstract**

**Aim:** This study was conducted to determine the occurrence of methicillin-sensitive and *Staphylococcus aureus* (MSSA) methicillin-resistant *S. aureus* (MRSA) from bovine mastitis and to characterize them with respect to antibiotic resistance gene *mecA*.

**Materials and Methods:** A total of 160 mastitic milk samples were screened for the presence of *S. aureus*. The presumptive positive isolates were confirmed using *nuc* and 23S rRNA gene-based polymerase chain reaction. All the confirmed isolates were subjected to *in vitro* antibiotic using a number of antibiotics. Isolates which showed resistance against methicillin were characterized for the presence of *mecA* gene.

**Results:** Out of the total 160 milk samples, 36 (22.5%) samples yielded *S. aureus*. The *in vitro* antibiotic revealed that 16.6% *S. aureus* isolates were resistant to all antibiotics screened for and 5.5% isolates were sensitive to all of them. Furthermore, the study found 94.4%, 83.3%, 77.7%, 66.6%, 50%, and 27.7% of *S. aureus* isolates resistant to penicillin, ampicillin, amoxicillin-sulbactam, enrofloxacin, ceftriaxone, and methicillin, respectively. Out of the 36 *S. aureus* isolates, only 6 (16.6%) isolates were confirmed as MRSA while rest were MSSA.

**Conclusion:** The higher occurrence of *S. aureus*-mediated mastitis was concluded due to improper hygienic and poor farm management. The multiple drug resistance reveals the indiscriminate use of drugs and presence of methicillin resistance gene determinant is an alarming situation as such infections are difficult to treat.

**Keywords:** bovine, mastitis, methicillin-resistant *Staphylococcus aureus*, *mecA*, methicillin-sensitive *Staphylococcus aureus*, *Staphylococcus aureus*.

**Introduction**

*Staphylococcus aureus* is a Gram-positive coccal bacterium found commonly as commensal on skin and mucous membrane of upper respiratory and lower urogenital tract of humans and various animal species [1,2]. It has an ability to colonize and infect a variety of host species, including humans, farm and companion animals and wildlife. In case of animals, it is a primary and most lethal agent because it causes chronic and deep infections in the mammary glands that is extremely difficult to be cured [3]. *S. aureus* is the most prevalent and contagious pathogen that is found in 30-40% of all mastitic cases and 80% of subclinical bovine mastitis which may result in about 35 billion US dollar annual losses worldwide [4,5].

The mastitis causing ability is governed by a number of virulence factors which are either structural or secretory [6]. The structural virulence factors include protein A, capsular polysaccharide, peptidoglycan and adhesions, while as secretory includes coagulase, lipase, hyaluronidase, proteases and hemolysins [7,8].

Over the recent past, it has become difficult to control the virulent strains of *S. aureus* from causing mastitis. The reason being some strains of *S. aureus* have become resistant to various β-lactam antibiotics including the powerful ones in this class, i.e., methicillin. Such strains of *S. aureus* are known as methicillin-resistant *S. aureus* (MRSA) [9]. Methicillin resistance is caused by the acquisition of a *mecA* gene. This produces an alternative penicillin-binding protein 2a (PBP2a), which has lower affinity for β-lactam antibiotics [10].

The increase in global prevalence of virulent and multidrug resistant *S. aureus* strains poses a renewed threat to the dairy industry which lays need to undertake research for addressing the issue. Hence, this study was aimed at isolation and molecular characterization of *S. aureus* isolates obtained from mastitic milk of various dairy farms in Jammu for methicillin governing gene determinant.
Materials and Methods

Ethical approval
The approval from the Institutional Animal Ethics Committee to carry out this study was not required as no invasive technique was used. The milk samples were collected from clinically affected animals with mastitis as per standard collection procedure.

Sampling
This study was based on a total of 160 milk samples (80 cows and 80 buffaloes) collected from clinical as well as subclinical mastitis cases. Before sampling, the udders were inspected for externally observed pathological condition. Each milk sample was collected aseptically in a sterile screw-capped bottle from each mammary gland after washing with water and cleaning the teats with cotton soaked in 70% ethanol. The samples were immediately taken to the laboratory for bacteriological analysis.

Isolation
Isolation of *S. aureus* was attempted according to the method previously described by Singh and Prakash with slight modification [11]. Enrichment was carried out in peptone water enrichment broth (HiMedia Pvt. Ltd., India). A loop full of milk sample was inoculated in sterile enrichment broth and incubated for 24 h at 37°C. Subsequently, a loop full of inoculum from enrichment broth was streaked on Baird Parker agar (HiMedia Pvt. Ltd., India). After 48 h of incubation at 37°C, colonies appeared as jet black surrounded by a white halo characteristic of *S. aureus*. The pure cultures were streaked on Nutrient agar slant and incubated for 24 h at 37°C and then stored at 4°C. The confirmation of the isolates as *S. aureus* was done by demonstration of the typical cellular morphology in Gram stained smears (Gram-positive cocci that occurred in clusters) and biochemical tests such as catalase, oxidase, DNase and coagulase, respectively.

Extraction of DNA
Suspensions of the bacterial colonies maintained on the nutrient agar slant were prepared in 1.5 ml microcentrifuge tubes in 250 μl of sterile double distilled water by gentle mixing. The samples were boiled for 10 min, cooled on ice for 10 min and centrifuged at 10,000×g for 5 min. 2 μl of the supernatant was used as the template for each polymerase chain reaction (PCR).

Molecular detection of *S. aureus*
The presumptive *S. aureus* isolates were confirmed by amplifying species-specific thermonuclease (*nuc*) gene as described previously [12]. The sequence of primers used is mentioned in Table-I. Isolates negative for *nuc* gene were subjected to another round of PCR using species-specific primers targeting the 23S rRNA gene [13].

Phenotypic detection of MRSA by oxacillin screening agar test
A bacterial suspension equal to 0.5 McFarland was smeared onto oxacillin resistance screening agar (ORSA) (HiMedia Pvt. Ltd., India), and the plate was incubated at 37°C for 24 h. Oxacillin resistance was confirmed by bacterial growth after 24 h of incubation at 37°C.

Antimicrobial sensitivity test
MRSA and methicillin sensitive and *S. aureus* (MSSA) isolates were subjected to disc diffusion antimicrobial sensitivity test on Mueller-Hinton agar plates (HiMedia, Mumbai, India) as per the previous protocol described by Bauer et al. [14]. The six different antimicrobial discs (HiMedia, Mumbai, India) used in this study were ampicillin, amoxicillin-sulbactam, ceftriaxone, enrofloxacin, methicillin, and pencillin.

Molecular detection of MRSA targeting *mecA* gene
All the *S. aureus* isolates were screened for the presence of *mecA* gene as per the method earlier described [12].

Results
From a total of 160 milk samples collected, 132 (82.5%) samples revealed jet black colonies surrounded by white halo indicating lecithinase activity on Baird Parker agar medium indicating presumptive *S. aureus* as shown in Figure-1. The Gram-staining showed all these isolates were Gram-positive cocci, but only 96 (72.7%) isolates showed characteristic positive catalase and negative oxidase tests and were regarded as presumptive *S. aureus*. From the 96 isolates, 72 (75%) isolates were positive for DNase test and showed typical depolymerization of DNA around the bacterial colonies on DNase agar as shown in Figure-2.

Molecular detection of *S. aureus*
Out of the 96 presumptive *S. aureus* isolates, 28 were confirmed as *S. aureus*, as revealed by the amplification of 270 bp product of *nuc* gene specific for

Table-I: The sequence of the primers for PCR amplification specific to different genes of *Staphylococcus aureus*.

| Primer name | Primer sequence (5’– 3’) | Reference | Size (bp) |
|-------------|-------------------------|-----------|-----------|
| nuc-1 F     | GGGATGGAGTGCTGATA CGGT | Louie et al. [12] | 270       |
| nuc-2 R     | AGCCAAGCCTGACGAACTAAGGC |            |           |
| Staur 4     | ACGGAGTTAC AAAGGCAGC   | Straub et al. [13] | 1250      |
| Staur 6     | AGCTAGCCCTTAACGAGTAC  |           |           |
| mecAF       | AAGATTCGATGTTAAGGGTGGC | Louie et al. [12] | 530       |
| mecAR       | AGTTCTGCAGTACGGGATTGC  |           |           |

PCR=Polymerase chain reaction
S. aureus (Figure-3). Out of the nuc gene negative isolates, 8 more were confirmed S. aureus in species-specific PCR targeting 23S rRNA gene (Figure-4). Thus, out of 96 presumptive isolates of S. aureus, 36 (37.5%) were found positive on the basis of molecular tests.

Phenotypic detection of MRSA isolates on ORSA

The methicillin resistance was ascertained to check the sensitivity and specificity of MRSA isolates in comparison to molecular detection of MRSA. Only 20 isolates showed growth on ORSA showing lesser sensitivity and specificity than molecular methods (Figure-5).

Antibiogram of S. aureus isolates

Antibiotic sensitivity assay revealed that out of 36 isolates, 34 (94.4%) of isolates were resistant to penicillin, 30 (83.3%) to ampicillin, 28 (77.7%) to amoxicillin-sulbactam, 24 (66.6%) to enrofloxacin, 18 (50%) were resistant to ceftriaxone, and 10 (27.7%) were resistant to methicillin. Two isolates were sensitive to all antibiotics used while as six isolates turned out to be resistant to all of them. The 10 methicillin-resistant isolates on antibiogram included six MRSA isolates which were confirmed by the presence of mecA gene.

Molecular detection of MRSA targeting mecA gene

Out of the total 36 confirmed S. aureus isolates, 6 (16.6%) isolates were confirmed to be MRSA when subjected to PCR amplification using specific primers for mecA gene. The PCR product appeared as a single band with a size close to the expected size of 533 bp (Figure-6).

Discussion

S. aureus causes one of the most common types of chronic mastitis in dairy animals worldwide. It has been found responsible for more than 80% of

Figure-1: Typical jet back colonies of Staphylococcus aureus surrounded by white halo showing lecithinase activity on Baried Parker agar.

Lane M: 100 bp ladder, Lane 1: Positive control of S. aureus, Lane 2: Negative control having distilled water as template, Lane 3, 4, 6: Isolate from mastitic milk samples positive for S. aureus indicated by 270 bp band, Lane 5: Isolate from mastitic milk samples negative for S. aureus.
subclinical bovine mastitis which results in huge economic losses to farmers in India [15]. In our study, out of 160 mastitic milk samples collected from different regions of Jammu province of India, only 22.5% of cases were found due to S. aureus. These results are comparatively lower than those formerly documented by some authors [16,17] who observed a prevalence of 30.6% and 55% which may be possibly because of improper hygiene and poor farm management practices. However, Unnerstad et al. [18] have also reported that the most frequently isolated bacterial species was S. aureus constituting 21.3% of the diagnoses carried out nationwide in Sweden. S. aureus isolates can be easily identified by cultural and biochemical tests, but these phenotypic characterization procedures are relative, so it is common practice to confirm the isolates with molecular tests. Two molecular tests one targeting the thermonuclease (nuc) gene [12] and other targeting the 23S rRNA gene [13] are well established. Only 28 (29.1%) isolates could be confirmed by nuc gene. However, nuc gene negative isolates showed further eight isolates positive for S. aureus in 23S rRNA specific-PCR. Hence, it is recommended that for molecular identification of S. aureus both nuc and 23SrRNA gene-specific PCR should be carried out. Even, when both the genes were targeted only 36 (37.5%) of presumptive isolates could be confirmed. This detection level of S. aureus from mastitic milk is low when compared with that of Kuzma et al. [19] and Bharathy et al. [20] who detected 100% and 65.57% of isolates positive by PCR. The probable reason may be due to other etiologic factors belonging to Enterobacteriaceae associated with mastitis.

MRSA is a feature of modern day health-care across the world. Methicillin resistance in staphylococci is mediated by the mecA gene, encoding the PBP2a, which has a reduced affinity for the penicillinase resistant penicillins like methicillin and oxacillin and for all other beta-lactam antibiotics [21]. In this investigation, 55.5% of the isolated S. aureus were phenotypically resistant to oxacillin and only 16.6% of isolated S. aureus strains were carrying the mecA gene and identified as MRSA. The variation in the phenotypic and the genotypic results may be due to the presence of MRSA encoding a divergent mecA gene. This divergent homolog is referred as mecC.

The emergence of antimicrobial resistance among animal pathogens is of growing concern in veterinary medicine as it renders antimicrobials ineffective for treating the animals. The antibiogram pattern revealed that 94.4% of all the isolates were resistant to penicillin. Similar results were obtained by Sori et al. [22] who reported that out of 86 pure isolates of S. aureus 87.2% were resistant to penicillin while as Khakpoor et al. [23] in other study reported that all isolate of S. aureus from mastitic cattle were resistant to penicillin. The occurrence of 83.3% resistance to ampicillin in this study is much higher than that of 41.44% as reported by Mubarack et al. [24] and lower as compared to 100% resistance reported by Khakpoor et al. [23]. In this study, 66.6% isolates turned out to be resistant to enrofloxacin. This is quite contrary to Hussain et al. [25] who report 94.73% and 69.56% S. aureus isolates were susceptible to enrofloxacin, respectively. The 50% resistance to ceftriaxone is almost in agreement with that of Khakpoor et al. [23] who reported 42.10% susceptibility to ceftriaxone.

**Conclusion**

Improper hygiene and poor farm managemental practices in the dairy farms could be responsible for contamination of udder resulting in mastitis. There is higher occurrence of S. aureus-mediated mastitis in Jammu region. For molecular identification of S. aureus both thermonuclease (nuc) gene and 23S rRNA gene-specific PCR should be used...
simultaneously as none of these tests cover all the *S. aureus* isolates individually. The variation in the phenotypic and the genotypic typing of *S. aureus* as MRSA and MSSA may be due to the presence of MRSA encoding a divergent mecA gene like mecC. Hence, it is recommended that both the variants should be covered for genotypic typing of *S. aureus*. Unusually, high resistance of *S. aureus* isolates to enrofloxacin indicates its indiscriminate use in clinical practice, hence alarming.

**Authors’ Contributions**

AT and MAB designed the study. Laboratory work was done by SH and AM. IAM and GAB prepared the manuscript and analyzed the data. SN done sampling of animals and isolation. All authors read and approved the final manuscript.
