Abstract We present the formal derivation of a new unidirectional model for unsteady mixed flows in non-uniform closed water pipes. In the case of free surface incompressible flows, the FS-model is formally obtained, using formal asymptotic analysis, which is an extension to more classical shallow water models. In the same way, when the pipe is full, we propose the P-model, which describes the evolution of a compressible inviscid flow, close to gas dynamics equations in a nozzle. In order to cope with the transition between a free surface state and a pressurized (i.e., compressible) state, we propose a mixed model, the PFS-model, taking into account changes of section and slope variation.

Keywords shallow water equations, unsteady mixed flows, free surface flows, pressurized flows, curvilinear transformation, asymptotic analysis

Notations

Notations concerning geometrical variables

- (0, i, j, k): Cartesian reference frame.
- ω(x, 0, b(x)): parametrization in the reference frame (0, i, j, k) of the plane curve C which corresponds to the main flow axis.
- (T, N, B): Serret-Frenet reference frame attached to C with T the tangent, N the normal and B the bi-normal vector.
- X, Y, Z: local variable in the Serret-Frenet reference frame with X the curvilinear abscissa, Y the width of pipe, Z the B-coordinate of any particle.
- σ(X, Z) = β(X, Z) − α(X, Z): width of the pipe at Z with β(X, Z) (resp. α(X, Z)) is the right (resp. left) boundary point at altitude Z.
- θ(X): angle (i, T).
- S(X): cross-section area.
- R(X): radius of the cross-section S(X).
- nwb: outward normal vector to the wet part of the pipe.

*Corresponding author
n: outward normal vector at the boundary point m in the \( \Omega \)-plane.

Notations concerning the free surface (FS) part

- \( \Omega(t,X) \): free surface cross section.
- \( H(t,X) \): physical water height.
- \( h(t,X) \): Z-coordinate of the water level.
- \( n_{fs} \): outward B-normal vector to the free surface.
- \( A \): wet area.
- \( Q \): discharge.
- \( \rho_0 \): density of the water at atmospheric pressure \( p_0 \).

Notations concerning the pressurized part

- \( \Omega(X) \): pressurized cross-section.
- \( \rho(t,X) \): density of the water.
- \( \beta \): water compressibility coefficient.
- \( c = \sqrt{\frac{1}{\beta \rho_0}} \): sonic speed.
- \( A = \frac{\rho}{\rho_0} S \): FS equivalent wet area.
- \( Q \): FS equivalent discharge.

Notations concerning the PFS model

- \( S \): the physical wet area: \( S = A \) if the state is free surface, \( S \) otherwise.
- \( H \): the Z coordinate of the water level: \( H = h \) if the state is free surface, \( R \) otherwise.

Other notations

- Bold characters are used for vectors except for \( S \).

1 Introduction

The present work takes place in the general framework of the modeling of unsteady mixed flows in any kind of closed domain taking into account the cavitation problem and air entrapment. We are interested in flows occurring in closed pipes with non-uniform sections, where some parts of the flow can be free surface (only a part of the pipe is filled) and other parts are pressurized (the pipe is full). The transition phenomenon between the two types of flows occurs in many situations such as storm sewers and waste or supply pipes in hydroelectric installations. It can be induced by a sudden change in the boundary conditions as failure pumping. During this process, the pressure can reach severe values and cause damage. The simulation of such a phenomenon is thus a major challenge and a great amount of work has been devoted to it these last years (see [12,15,24,25] for instance). Recently, Fuamba [17] proposed a model for the transition from a free surface flow to a pressurized one in a way very close to ours.

The classical shallow water equations are commonly used to describe free surface flows in open channels. They are also used in the study of mixed flows using the Preissman slot artefact (see for example [12,25]). However, this technique does not take into account the depressurization phenomenon which occurs during a water hammer. On the other hand, the Allievi equations, commonly used to describe pressurized flows, are written in a non-conservative form which is not well adapted to a natural coupling with the shallow water equations.

A model for the unsteady mixed water flows in closed pipes and a finite volume discretization have been previously studied by two of the authors [6] and a kinetic formulation has been proposed in [8]. We propose here the PFS-model which tends to extend naturally the work in [6] in the case of a closed pipe with non-uniform section. For the sake of simplicity, we do not deal with the deformation of the domain induced by the change of pressure. We will consider only an infinitely rigid pipe.
The paper is organized as follows. Section 2 is devoted to the derivation of the free surface model from the 3D incompressible Euler equations which are written in a suitable local reference frame in order to take into account the local effects produced by the changes of section and the slope variation. To this end, we present two models derived by two techniques inspired by the work in [3] and [18]. The first one consists in taking the mean value in the Euler equations along the normal section to the main axis. The obtained model provides a description taking into account the geometry of the domain, namely the changes of section and also the inertia strength produced by the slope variation. The second one is a formal asymptotic analysis. In this approach, we seek an approximation at the first order and, by comparison with the previous model, the term related to the inertia strength vanishes since it is a term of second order. We obtain the FS-model. In Section 3, we follow the derivation of the FS-model and we derive the model for pressurized flows, called the P-model, from the 3D compressible Euler equations by a formal asymptotic analysis. Writing the source terms into a unified form and using the same couple of conservative unknowns as in [7], we propose in Section 4 a natural model for mixed flows that we call the PFS-model, which ensures the continuity of the unknowns and the source terms.

2 Formal derivation of the free surface model

The classical shallow water equations are commonly used to describe physical situations like rivers, coastal domains, oceans and sedimentation problems. These equations are obtained from the incompressible Euler system (see e.g. [1,19]) or from the incompressible Navier-Stokes system (see for instance [10,11,18,21]) by several techniques (e.g. by direct integration or asymptotic analysis or as in [14] and especially as proposed by Bouchut et al. [3,4] upon which the PFS-model is based).

In order to formally derive a unidirectional shallow water type equation for free surface flow in a closed water pipe with varying slope and section, we consider that the length of the pipe is larger than the diameter and we write the incompressible Euler equations in a local Serret-Frenet frame attached to a given plane curve (generally the main pipe axis, see Remark 4.1). Then, taking advantage of characteristic scales, we perform a thin layer asymptotic analysis with respect to some small parameter \( \varepsilon = \frac{H}{L} \) which is also assumed to be proportional to the vertical, \( W \) and horizontal, \( U \) ratio of the fluid movements, i.e., \( \varepsilon = \frac{W}{U} \). This assumption translates the fact that in such a domain, the flow follows a main flow axis. Finally, the equations are vertically averaged along orthogonal sections to the given plane curve and we get the Free Surface model called the FS-model.

Throughout this section, we only consider pipes with variable circular section. However, this analysis can be easily adapted to any type of closed pipes.

Let \((O, i, j, k)\) be a convenient Cartesian reference frame, for instance the canonical basis of \(\mathbb{R}^3\). The Euler equations in Cartesian coordinates are:

\[
\begin{align*}
\text{div}(\rho_0 \mathbf{U}) &= 0, \\
\partial_t (\rho_0 \mathbf{U}) + \rho_0 \mathbf{U} \cdot \nabla \mathbf{U} + \nabla P &= \rho_0 \mathbf{F},
\end{align*}
\]

where \(\mathbf{U}(t, x, y, z)\) is the velocity field of components \((u, v, w)\), \(P = p(t, x, y, z)I_3\) is the isotropic pressure tensor, \(\rho_0\) is the density of the water at atmospheric pressure and \(\mathbf{F}\) is the exterior strength of gravity given by

\[
\mathbf{F} = -g \begin{pmatrix}
-\sin \theta(x) \\
0 \\
\cos \theta(x)
\end{pmatrix},
\]

where \(\theta(x)\) is the angle \((i, T)\) in the \((i, k)\)-plane (cf. Figure 1 or Figure 2) with \(T\) the tangent vector (defined below) and \(g\) is the gravity constant.

We introduce a characteristic function, \(\phi\), in order to define the fluid area (as in [18,21]):

\[
\phi = \begin{cases}
1, & \text{if } z \in \Omega(t, x), \\
0, & \text{otherwise},
\end{cases}
\]

(2.2)
where \( \Omega(t,x) \) is the wet section (2.5). Using the divergence free equation, we obviously find the equation on \( \phi \):

\[
\partial_t (\rho \phi) + \text{div}(\rho \phi \mathbf{U}) = 0.
\]

(2.3)

Remark 2.1. This equation allows us to get the kinematic free surface condition:

any free surface particle follows the fluid streamline.

On the wet boundary \((\text{fm})\), we assume a no-leak condition: \( \mathbf{U} \cdot \mathbf{n}_{\text{fm}} = 0 \), where \( \mathbf{n}_{\text{fm}} \) is the outward unit normal vector to the wet boundary (as displayed on Figure 2). We also assume that the pressure at the free surface level is equal to the atmospheric pressure (which is assumed to be zero in the rest of the paper for the sake of simplicity).

We define the domain \( \Omega_F(t) \) of the flow at time \( t \) as the union of sections, \( \Omega(t,x) \), assumed to be simply connected compact sets, orthogonal to some plane curve \( C \). We define the parametric representation of this curve by \( x \rightarrow (x,0,b(x)) \) in the plane \((O,i,j,k)\), where \( k \) is the vertical axis, \( b(x) \) is the elevation of the point \( \omega(x,0,b(x)) \) in the \((O,i,j)\)-plane (cf. Figure 1).

Setting

\[
X = \int_{x_0}^{x} \sqrt{1 + \left( \frac{d b(\xi)}{d \xi} \right)^2} \, d\xi
\]

(2.4)
as the curvilinear variable, where \( x_0 \) is a given abscissa, \( Y = y \), the variable “width” and \( Z \) the \( \mathbf{B} \)-coordinate (i.e., the elevation of a fluid particle \( M \) along the \( \mathbf{B} \) vector as defined below), we define the
local reference of origin \( \omega(x,0,b(x)) \) and by the basis \((T,N,B)\), where \( T \) is the unit tangent vector, \( N \) the unit normal vector and \( B \) the unit bi-normal vector attached to the plane curve \( C \) at the point \( \omega(x,0,b(x)) \) (see Figures 1 and 3 for notations). In the \((O,i,k)\)-plane, the vector \( B \) is normal to the curve \( C \).

With these notations, for every point \( \omega \in C \), the wet section \( \Omega(t,X) \) can be defined by the following set:

\[
\Omega(t,X) = \{(Y,Z) \in \mathbb{R}^2; Z \in [-R(X),-R(X)+H(t,X)], Y \in [\alpha(X,Z),\beta(X,Z)]\},
\]

where \( R(X) \) is the radius of the pipe section \( S(X) = \pi R^2(X) \) and \( H(t,X) \) is the physical water height.

We note \( \alpha(X,Z) \) (resp. \( \beta(X,Z) \)) the left (resp. right) boundary point at elevation \( Z \), for \(-R(X) \leq Z \leq R(X) \) (as displayed in Figure 3). We also assume that the supports of the functions \( \alpha(\cdot,z) \) and \( \beta(\cdot,z) \) are compact in \([-R(X),R(X)]\). Finally, we denote the \( Z \)-coordinate of the water height by \( h(t,X) = -R(X)+H(t,X) \).

In what follows, we will assume that the following condition holds:

(H) Let \( R(x) \) be the algebraic curvature radius at the point \( \omega(x,0,b(x)) \). Then, for every \( x \in C \), we have

\[ |R(x)| > R(x). \]

**Remark 2.2.** This geometric condition ensures that the application \( \mathcal{T} : (x,y,z) \to (X,Y,Z) \) is a \( C^1 \)-diffeomorphism. In other words, it simply means that for a given fluid particle, there exists a unique point \( \omega \in C \) as displayed in Figure 4.

### 2.1 Incompressible Euler equations in curvilinear coordinates

Following Bouchut et al. [3, 4], we write the previous system (2.1) in the local frame of origin \( \omega(x,0,b(x)) \) and of basis \((T,N,B)\) by the following change of variables \( \mathcal{T} : (x,y,z) \to (X,Y,Z) \) using the divergence chain rule that we recall here:

**Lemma 2.3.** Let \( (X,Y,Z) \leftrightarrow \mathcal{T}(X,Y,Z) = (x,y,z) \) be a \( C^1 \)-diffeomorphism and \( A^{-1} = \nabla_{(X,Y,Z)} \mathcal{T} \) be the Jacobian matrix with determinant \( J \). Then, for every vector field \( \Phi \), we have

\[ J \text{div}_{(x,y,z)} \Phi = \text{div}_{(X,Y,Z)} (J A \Phi), \]

and, for every scalar function \( f \), we have

\[ \nabla_{(x,y,z)} f = A^T \nabla_{(X,Y,Z)} f, \]

where \( A^T \) is the transposed matrix of \( A \).
Let \((U, V, W)^T\) be the components of the vector field in variables \((X, Y, Z)\), such that
\[
(U, V, W)^T = \Theta(u, v, w)^T,
\]
where \(\Theta\) is the rotation matrix generated around the axis \(j\):
\[
\Theta = \begin{pmatrix}
\cos \theta & 0 & \sin \theta \\
0 & 1 & 0 \\
-\sin \theta & 0 & \cos \theta 
\end{pmatrix}.
\]

2.1.1 Transformation of the divergence equation

A given point \(M\) of coordinates \((x, y, z)\) such that:
\[
M(x, y, z) = (x - Z \sin \theta(x) , y , x + Z \cos \theta(x))
\]
(in the \((O, i, j, k)\)-basis) has \((X, Y, Z)\)-coordinate in the local frame generated by the basis \((T, N, B)\) from origin \(\omega\) and the matrix \(A^{-1}\) (appearing in Lemma 2.3) reads as follows:
\[
A^{-1} = \begin{pmatrix}
\frac{dx}{dX} - Z \frac{d\theta}{dX} \cos \theta(X) & 0 & \sin \theta(X) \\
0 & 1 & 0 \\
\frac{db}{dX} - Z \frac{d\theta}{dX} \sin \theta(X) & 0 & \cos \theta(X)
\end{pmatrix}
\]
\[
= \begin{pmatrix}
J \cos \theta & 0 & \sin \theta \\
0 & 1 & 0 \\
J \sin \theta & 0 & \cos \theta
\end{pmatrix},
\]
where
\[
\frac{dx}{dX} = \frac{1}{\sqrt{1 + (\frac{db}{dx}(x(X, Y, Z)))^2}} = \cos \theta(X), \quad \frac{db(X)}{dX} = \sin \theta(X),
\]
and
\[
J(X, Y, Z) := \det(A^{-1}) = 1 - Z \frac{d\theta(X)}{dX}
\]
with $J(X,Y,Z) = J(X,Z)$.

Then we have

$$
A = \frac{1}{J} \begin{pmatrix}
\cos \theta & 0 & \sin \theta \\
0 & 1 & 0 \\
-J\sin \theta & 0 & J\cos \theta
\end{pmatrix},
$$

(2.7)

and using Lemma 2.3, the free divergence equation in variables $(X,Y,Z)$ is

$$
J \text{div}_{x,y,z}(\boldsymbol{U}) = \text{div}_{X,Y,Z} \begin{pmatrix} U \\ Jv \\ JW \end{pmatrix} = 0,
$$

i.e.,

$$
\partial_X U + \partial_Y (JU) + \partial_Z (JW) = 0.
$$

(2.8)

Remark 2.4. The application $(x,y,z) \rightarrow M(x,y,z)$ is a $C^1$-diffeomorphism since $J(X,Z) > 0$ in view of the assumption $(H)$.

2.1.2 Transformation of the equation of conservation of the momentum

Following the previous paragraph, using Lemma 2.3 to the scalar convection equation characterized by the speed $\boldsymbol{U}$ which is a divergence free field, we get the following identity:

$$
J(\partial_t + \boldsymbol{U} \cdot \nabla) f = J(\partial_t f + \text{div}(f\boldsymbol{U})) = J\text{div}_{t,x,y,z} \begin{pmatrix} Jf \\ J\partial_t f \\ Jf\partial_Y f \\ Jf\partial_Z f \end{pmatrix},
$$

where $A^{-1}$ is the inverse matrix of $A$ given by (2.7). Thus, we have

$$
J(\partial_t + \boldsymbol{U} \cdot \nabla) f = \partial_t (Jf) + \partial_X (JfU) + \partial_Y (JfV) + \partial_Z (JfW),
$$

(2.9)

Performing a left multiplication of the equation of conservation of the momentum (2.1) by $J\Theta$, where the source term is written as $\mathbf{F} = -\nabla (g \cdot M)$ (for a point $M$ defined as previously (2.6)), we get

$$
0 = J\Theta(\partial_t \boldsymbol{U} + \boldsymbol{U} \cdot \nabla \boldsymbol{U} + \text{div}(P/\rho_0) + \nabla (g \cdot M))
= J(\partial_t (\Theta\boldsymbol{U}) + (\Theta\boldsymbol{U} \cdot \nabla)\boldsymbol{U}) + J\Theta\text{div}(P/\rho_0) + J\Theta\nabla (g \cdot M)
= J \left[ \begin{array}{c}
\partial_t \\
\partial_Y \\
\partial_Z
\end{array} \right] \begin{pmatrix}
U \\
V \\
W
\end{pmatrix} + \left[ \begin{array}{c}
(U \cdot \nabla u) \cos \theta + (U \cdot \nabla w) \sin \theta \\
(U \cdot \nabla v) \\
-(U \cdot \nabla u) \sin \theta + (U \cdot \nabla w) \cos \theta
\end{array} \right]
+ \left[ \begin{array}{c}
J\text{div}(\psi i) \cos \theta + J\text{div}(\psi k) \sin \theta \\
J\text{div}(\psi j) \\
-J\text{div}(\psi i) \sin \theta + J\text{div}(\psi k) \cos \theta
\end{array} \right],
$$

where $\psi := (p + g(b + Z \cos \theta))/\rho_0$.

Then, we proceed in two steps:

Computation of (a). We have

$$
J \left[ \begin{array}{c}
\partial_t U + (U \cdot \nabla u) \cos \theta + (U \cdot \nabla w) \sin \theta \\
\partial_t V + U \cdot \nabla v \\
\partial_t W + -(U \cdot \nabla u) \sin \theta + (U \cdot \nabla w) \cos \theta
\end{array} \right],
$$
\[
\begin{array}{c}
\frac{\partial_t U + U \cdot \nabla U - WU \cdot \nabla \theta}{\partial_t V + U \cdot \nabla V} \\
\frac{\partial_t W + U \cdot \nabla W + UU \cdot \nabla \theta}
\end{array}
\] (2.10)

Applying successively the identity (2.9) with \( f = U, V, W \), we get

\[
\partial_t \begin{pmatrix} JU \\ JV \\ JW \end{pmatrix} + \text{div}_{X,Y,Z} \begin{pmatrix} U \\ JV \\ JW \end{pmatrix} \otimes \begin{pmatrix} U \\ JV \\ JW \end{pmatrix} - iUW \frac{d \theta}{dX} + kU^2 \frac{d \theta}{dX}.
\] (2.11)

**Computation of (b).** Applying again Lemma 2.3, we show that the three following identities hold for every scalar function \( \psi \):

\[
\begin{align*}
J \text{div}(\psi i) &= \text{div}_{X,Y,Z} \begin{pmatrix} \psi \cos \theta \\ 0 \\ -J\psi \sin \theta \end{pmatrix}, \\
J \text{div}(\psi j) &= \partial_Y(J\psi), \\
J \text{div}(\psi k) &= \text{div}_{X,Y,Z} \begin{pmatrix} \psi \sin \theta \\ 0 \\ J\psi \cos \theta \end{pmatrix}.
\end{align*}
\] (2.12)

Moreover, we have

\[
\begin{align*}
\partial_X(\psi \cos \theta) \cos \theta + \partial_X(\psi \sin \theta) \sin \theta &= \partial_X \psi, \\
\partial_Z(\psi \cos \theta) \cos \theta - \partial_Z(\psi \sin \theta) \sin \theta &= 0,
\end{align*}
\] (2.13)

and

\[
\begin{align*}
\partial_X(\psi \sin \theta) \cos \theta - \partial_X(\psi \cos \theta) \sin \theta &= \psi \partial_X \theta, \\
\partial_Z(\psi \cos \theta) \cos \theta + \partial_Z(\psi \sin \theta) \sin \theta &= \partial_Z(\psi J).
\end{align*}
\] (2.14)

In view of equalities (2.12)–(2.14) applied to the quantity \( \psi := (p + g(b + Z \cos \theta))/\rho_0 \), the term (b) reads as follows:

\[
\begin{pmatrix}
\partial_X(\psi) \\
\partial_Y(\psi) \\
\psi \partial_X \theta + \partial_Z(\psi)
\end{pmatrix}.
\] (2.15)

Finally, gathering the results (2.11)–(2.15), the incompressible Euler equations in variables \((X, Y, Z)\) are

\[
\begin{align*}
\partial_t(p_0 U) + \partial_Y(Jp_0 V) + \partial_Z(Jp_0 W) &= 0, \\
\partial_t(Jp_0 U) + \partial_X(Jp_0 U^2) + \partial_Y(Jp_0 UV) + \partial_Z(Jp_0 UW) + \partial_X p &= G_1, \\
\partial_t(Jp_0 V) + \partial_X(Jp_0 UV) + \partial_Y(Jp_0 V^2) + \partial_Z(Jp_0 VW) + \partial_Y(p) &= 0, \\
\partial_t(Jp_0 W) + \partial_X(Jp_0 UW) + \partial_Y(Jp_0 VW) + \partial_Z(Jp_0 W^2) + \partial_Y(p) &= G_2,
\end{align*}
\] (2.16)

where

\[
G_1 = p_0 UW \frac{d \theta}{dX} - gp_0 J \sin \theta, \\
G_2 = -p_0 U^2 \frac{d \theta}{dX} - Jgp_0 \cos \theta.
\] (2.17)

The no-leak condition, with respect to the new variables, becomes

\[
\begin{pmatrix} U \\ V \\ W \end{pmatrix} \cdot \text{nfm} = 0,
\] (2.18)
where
\[
\mathbf{n}_{\text{fm}} = \frac{1}{\cos \theta(X)} \begin{pmatrix} -\sin \theta(X) \\ 0 \\ \cos \theta(X) \end{pmatrix}.
\]

The condition at the free surface, in the new variables, reads
\[
p(t, X, Y, Z = h(t, X)) = 0.
\]

\[\text{(2.19)}\]

2.1.3 Formal asymptotic analysis

Taking advantage of the ratio of the domain, we perform a formal asymptotic analysis of the equations (2.16) with respect to a small parameter \( \varepsilon \). Particularly, we are interested in the approximation at main order. In that case, we will get \( J \equiv 1 \).

To this end, let \( \textbf{\mathcal{L}} = \frac{1}{r} = \frac{L}{H} = \frac{L}{l} \) be the ratio aspect of the pipe, assumed to be very large. \( H, L \) and \( l \) are, respectively, the characteristic height, length and width (to simplify, \( l = H \) as the pipe, here, is assumed with circular cross-section). In the same way, denoting by \((\mathbf{\nabla}, \mathbf{W})\) the characteristic speed following the normal and bi-normal direction, \( \mathbf{U} \) the characteristic speed following the main pipe axis, we also assume that
\[
\varepsilon = \frac{L}{T}, \quad P = \rho_0 \mathcal{U}^2.
\]

Let \( T \) and \( P \) be the characteristic time and pressure such that
\[
\mathbf{U} = \frac{L}{T}, \quad P = \rho_0 \mathbf{U}^2.
\]

We set the following non-dimensioned variables:
\[
\mathcal{U} = \frac{U}{\mathbf{U}}, \quad \mathbf{V} = \varepsilon V, \quad \mathbf{W} = \varepsilon W, \\
\tilde{X} = \frac{X}{L}, \quad \tilde{Y} = \frac{Y}{H}, \quad \tilde{Z} = \frac{Z}{H}, \quad \tilde{P} = \frac{p}{P}, \quad \tilde{\theta} = \theta.
\]

Under these assumptions, the rescaled Jacobian is
\[
\tilde{J}(\tilde{X}, \tilde{Y}, \tilde{Z}) = 1 - \varepsilon \tilde{Z} \frac{d\tilde{\theta}}{d\tilde{X}}.
\]

Then, the non-dimensioned system (2.16) is reduced to
\[
\begin{align*}
\partial_{\tilde{X}} \mathcal{U} + \partial_{\tilde{Y}} (\tilde{J} \mathcal{V}) + \partial_{\tilde{Z}} (\tilde{J} \mathcal{W}) &= 0, \\
\varepsilon \partial_{\tilde{T}} (\tilde{J} \mathcal{U}) + \partial_{\tilde{X}} (\tilde{U}^2) + \partial_{\tilde{Y}} (\tilde{J} \tilde{U} \tilde{V}) + \partial_{\tilde{Z}} (\tilde{J} \tilde{U} \tilde{W}) + \partial_{\tilde{X}} \tilde{p} &= G_1, \\
\varepsilon^2 (\partial_{\tilde{T}} (\tilde{J} \mathcal{V}) + \partial_{\tilde{X}} (\tilde{U} \mathcal{V}) + \partial_{\tilde{Y}} (\tilde{J} \mathcal{V}^2) + \partial_{\tilde{Z}} (\tilde{J} \tilde{V} \tilde{W}) + \partial_{\tilde{Y}} (\tilde{J} \tilde{V} \tilde{P}) &= 0, \\
\varepsilon^2 (\partial_{\tilde{T}} (\tilde{J} \mathcal{W}) + \partial_{\tilde{X}} (\tilde{U} \mathcal{W}) + \partial_{\tilde{Y}} (\tilde{J} \mathcal{W}^2) + \partial_{\tilde{Z}} (\tilde{J} \tilde{W} \tilde{V}) + \tilde{J} \partial_{\tilde{Z}} (\tilde{J} \tilde{p}) &= G_2,
\end{align*}
\]

where
\[
G_1 = \varepsilon \mathcal{U} \mathcal{V} \frac{d\tilde{\theta}}{d\tilde{X}} - \frac{\tilde{Z}}{F_{r, L}^2} \frac{d}{d\tilde{X}} \cos \tilde{\theta} (\tilde{X}),
\]
\[
G_2 = -\varepsilon \tilde{U} \mathcal{V} \frac{d\tilde{\theta}}{d\tilde{X}} - \frac{\tilde{Z}}{F_{r, H}^2} \frac{d}{d\tilde{X}} \cos \tilde{\theta} (\tilde{X}) + \varepsilon \frac{d}{d\tilde{X}} \frac{\tilde{Z} \tilde{J} \cos \tilde{\theta} (\tilde{X})}{F_{r, H}^2},
\]

\( F_{r, \chi} = \frac{\Omega}{\sqrt{\rho \chi}} \) is the Froude number following the axis \( \mathbf{T}, \mathbf{B} \) or \( \mathbf{N} \) with \( \chi = L \) or \( \chi = H \).

Formally, taking \( \varepsilon = 0 \) in the previous equation, we get
\[
\partial_{\tilde{X}} \mathcal{U} + \partial_{\tilde{Y}} \mathcal{V} + \partial_{\tilde{Z}} \mathcal{W} = 0,
\]

\[\text{(2.21)}\]
we get the following equation:
\[
\frac{\partial}{\partial t} \tilde{U} + \frac{\partial}{\partial x}(\tilde{U}^2) + \frac{\partial}{\partial y}(\tilde{U} \tilde{V}) + \frac{\partial}{\partial z}(\tilde{U} \tilde{W}) + \frac{\partial}{\partial X} \tilde{P} = -\frac{\sin \tilde{\theta}(X)}{F_{r, L}^2} - \frac{\tilde{Z}}{F_{r, H}^2} \frac{d}{dX} \cos \tilde{\theta}(X),
\]
\[
\frac{\partial}{\partial t} \tilde{P} = 0,
\]
\[
\frac{\partial}{\partial z} \tilde{P} = - \frac{\cos \tilde{\theta}(X)}{F_{r, H}^2}.
\]

Henceforth, we denote \((x, y, z)\) the dimensioned variables \((X, Y, Z)\) and \((u, v, w)\) the dimensioned speed \((U, V, W)\). In particular, we set
\[
x = L \tilde{X}, \quad y = H \tilde{Y}, \quad z = H \tilde{Z}
\]
and
\[
u = \overline{U}, \quad v = \overline{U} \tilde{V}, \quad v = \overline{U} \tilde{W}\]
and \(p = \rho_0 \overline{U}^2 \tilde{P}\).

Then, multiplying the equation (2.21) by \(\rho_0 \overline{U} \tilde{P}\), (2.22) by \(\rho_0 \overline{V} \tilde{P}\), (2.23) by \(\rho_0 \overline{W} \tilde{P}\), (2.24) by \(\rho_0 \overline{U} \tilde{P}\), we obtain the hydrostatic approximation of the Euler equations (2.16):
\[
\frac{\partial}{\partial t} (\rho_0 u) + \frac{\partial}{\partial x} (\rho_0 u^2) + \frac{\partial}{\partial y} (\rho_0 uv) + \frac{\partial}{\partial z} (\rho_0 uw) + \frac{\partial}{\partial x} p = -g_0 \sin \theta(x) - g_0 z \frac{d}{dx} \cos \theta(x),
\]
\[
\frac{\partial}{\partial y} p = 0,
\]
\[
\frac{\partial}{\partial z} p = -g \cos \theta(x).
\]

2.1.4 Vertical averaging of the hydrostatic approximation of Euler equations

Let \(A(t, x)\) and \(Q(t, x)\) be the conservative variables of wet area and discharge defined by the following relations:
\[
A(t, x) = \int_{\Omega(t, x)} dy dz
\]
and
\[
Q(t, x) = A(t, x) \overline{u}(t, x),
\]
where
\[
\overline{u}(t, x) = \frac{1}{A(t, x)} \int_{\Omega(t, x)} u(t, x, y, z) dy dz
\]
is the mean speed of the fluid over the section \(\Omega(t, x)\).

Kinematic boundary condition and the equation of the conservation of the mass. Let \(\mathbf{V}\) be the vector field \(\left(\begin{array}{c} u \\ v \\ w \end{array}\right)\). Integrating the equation of conservation of the mass (2.3) on the set
\[
\Omega(x) = \{(y, z); \alpha(x, z) \leq y \leq \beta(x, z), -R(x) \leq y \leq \infty\},
\]
we get the following equation:
\[
\int_{\Omega(x)} \frac{\partial}{\partial t} (\rho_0 \phi) + \frac{\partial}{\partial x} (\rho_0 \phi u) + \frac{\partial}{\partial y} (\rho_0 \phi v) + \frac{\partial}{\partial z} (\rho_0 \phi w) dy dz = \rho_0 \left( \frac{\partial}{\partial x} A + \frac{\partial}{\partial z} Q + \int_{\partial \Omega_{\text{fin}}(t, x)} (u \frac{\partial}{\partial x} M - \mathbf{V}) \cdot \mathbf{n} ds \right),
\]
where \(A\) and \(Q\) are given by (2.29) and (2.30).

According to the definition (2.2) of \(\phi\), the boundary \(\Omega_{\text{fin}}\) coincides with \(\gamma_{\text{fin}}\). Using the no-leak condition (2.18), Equation (2.32) is equivalent to
\[
\frac{\partial}{\partial t} (\rho_0 A) + \frac{\partial}{\partial z} (\rho_0 Q) = 0.
\]

Now, if we integrate the equation (2.3) on \(\Omega(t, x)\), we get
\[
\rho_0 \left( \int_{-R(x)}^{h(t, x)} \frac{\partial}{\partial x} \right) \int_{a(x, z)}^{b(x, z)} dy dz + \frac{\partial}{\partial z} Q + \int_{\partial \Omega(t, x)} (\mathbf{V} - u \frac{\partial}{\partial x} M) \cdot \mathbf{n} ds = 0,
\]
of the momentum of the free surface model, we integrate each term of \((2.26)\) along sections \(\Omega(t,x)\),

\[
\int_{\gamma_{im}(t,x)} (\mathbf{V} - u \partial_x M) \cdot \mathbf{n}_{im} \, ds = 0.
\]

Then, we deduce

\[
\partial_t (p_0 A) + \partial_x (p_0 Q) + p_0 \int_{\gamma_{ai}(t,x)} (\partial_t M + u \partial_x M - \mathbf{V}) \cdot \mathbf{n}_{a1} \, ds = 0. \quad (2.35)
\]

By comparing equations \((2.33)\) and \((2.35)\), we finally get the kinematic condition at the free surface:

\[
\int_{\gamma_{ai}(t,x)} (\partial_t M + u \partial_x M - \mathbf{V}) \cdot \mathbf{n}_{a1} \, ds = 0, \quad (2.36)
\]

and we deduced from \((2.35)\) the following equation of the conservation of the mass:

\[
\partial_t (p_0 A) + \partial_x (p_0 Q) = 0. \quad (2.37)
\]

**Equation of the conservation of the momentum.** In order to get the equation of the conservation of the momentum of the free surface model, we integrate each term of \((2.26)\) along sections \(\Omega(t,x)\) as follows:

\[
\iint_{\Omega} \left( \partial_t (\rho_0 u) + \partial_x (\rho_0 u^2) + \partial_y (\rho_0 v) + \partial_z (\rho_0 w) \right) \, dydz = \iint_{\Omega} \left( -\rho_0 g z \frac{d}{dx} \frac{\cos \theta - \rho_0 g \sin \theta}{\rho_0} \right) \, dydz,
\]

where \(\mathbf{V} = (u, v, w)\). Assuming that 

\[
\bar{u} v \approx \bar{u} \bar{v}, \quad \bar{u}^2 \approx \bar{V}^2,
\]

we successively get:

**Computation of the term \(\int_{\Omega(t,x)} a_1 \, dydz\).** The pipe is non-deformable, only the integral at the free surface is relevant:

\[
\int_{\gamma_{im}(t,x)} \rho_0 u \partial_t M \cdot \mathbf{n}_{im} \, ds = 0.
\]

So we get

\[
\int_{\Omega(t,x)} \partial_t (\rho_0 u) \, dydz = \partial_t \int_{\Omega(t,x)} \rho_0 u \, dydz - \int_{\gamma_{ai}(t,x)} \rho_0 u \partial_t M \cdot \mathbf{n}_{a1} \, ds.
\]

**Computation of the term \(\int_{\Omega(t,x)} a_2 \, dydz\).** We have

\[
\int_{\Omega(t,x)} \partial_x (\rho_0 u^2) \, dydz = \partial_x \int_{\Omega(t,x)} \rho_0 u^2 \, dydz - \int_{\gamma_{ai}(t,x)} \rho_0 u^2 \partial_x M \cdot \mathbf{n}_{a1} \, ds - \int_{\gamma_{im}(t,x)} \rho_0 u^2 \partial_x M \cdot \mathbf{n}_{im} \, ds.
\]

**Computation of the term \(\int_{\Omega(t,x)} a_3 \, dydz\).** We have

\[
\int_{\Omega(t,x)} \partial_y (\rho_0 \mathbf{V}) \, dydz = \int_{\gamma_{im}(t,x)} \rho_0 \mathbf{V} \cdot \mathbf{n}_{im} \, ds + \int_{\gamma_{ai}(t,x)} \rho_0 \mathbf{V} \cdot \mathbf{n}_{a1} \, ds.
\]

Summing the result of the previous step \(a_1 + a_2 + a_3\), we get

\[
\int_{\Omega(t,x)} (a_1 + a_2 + a_3) \, dydz = \partial_t (\rho_0 Q) + \partial_x \left( \frac{\rho_0 Q^2}{A} \right), \quad (2.38)
\]
where $A$ and $Q$ are given by (2.29) and (2.30).

**Computation of the term $\int_{\Omega(t,x)} \alpha_4 \, dy dz$.** Let us first note that the pressure is hydrostatic:

$$p(t, x, z) = \rho_0 g (h(t, x) - z) \cos \theta(x),$$

(2.39)

since from the equation (2.27), the pressure does not depend on the variable $y$. Equation (2.39) follows immediately by integrating the equation (2.28) from $z$ to $h(t, x)$.

For $\psi = p, p$ given by the relation (2.39), $(t, x)$ fixed, we have

$$\int_{\Omega(t,x)} \partial_x \psi \, dy dz = \int_{-R(x)}^{h(t,x)} \int_{\alpha(x,z)}^{\beta(x,z)} \partial_x \psi \, dy dz
= \int_{-R(x)}^{h(t,x)} \partial_x \int_{\alpha(x,z)}^{\beta(x,z)} \psi \, dy dz
= \left( \int_{-R(x)}^{h(t,x)} \partial_x \beta(x, z) \psi|_{y=\beta(x,z)} - \partial_x \alpha(x, z) \psi|_{y=\alpha(x,z)} \, dz \right)
= \partial_x \int_{-R(x)}^{h(t,x)} \psi \, dy dz
- \left( \int_{-R(x)}^{h(t,x)} \partial_x \beta(x, z) \psi|_{y=\beta(x,z)} - \partial_x \alpha(x, z) \psi|_{y=\alpha(x,z)} \, dz \right)
- \partial_x h(t, x) \int_{\alpha(x,h(t,x))}^{\beta(x,h(t,x))} \psi|_{z=h(t,x)} \, dy - \partial_x R(x) \int_{\alpha(x,h(t,x))}^{\beta(x,h(t,x))} \psi|_{z=-R(x)} \, dy.
$$

Finally, we have

$$\int_{\Omega(t,x)} \partial_x p \, dy dz = \partial_x (\rho_0 g I_1(x, A(t,x)) \cos \theta(x)) - g \rho_0 I_2(x, A) \cos \theta(x)
- \rho_0 g (h(t, x) + R(x)) \cos \theta(x) \sigma(x, -R(x)) \frac{d R(x)}{dx},$$

(2.40)

where $I_1$ is the hydrostatic pressure:

$$I_1(x, A) = \int_{-R(x)}^{h(A)} (h(A) - z) \sigma(x, z) \, dz.$$    (2.41)

When the sections of the pipe are rectangular and uniform, we have $I_1(x, A) := I_1(A)$ and $\sigma(x, z) = \sigma = cte$. Moreover, we have $A = (h + R) \sigma = H \sigma$ and the pressure reads

$$\frac{g I_1(A)}{\sigma} = \frac{g I_1(A)}{\sigma} = \frac{g H^2}{2},$$

as in the usual formulation of the mono-dimensional Saint-Venant equations.

We can also regard $I_1/A = \mathfrak{f}$ as the distance separating the free surface to the center of the mass of the wet section (see Figure 5).

The term $I_2$ is the pressure source term:

$$I_2(x, A) = \int_{-R(x)}^{h(A)} (h(A) - z) \partial_x \sigma(x, z) \, dz.$$    (2.42)

It takes into account the section variation via the term $\partial_x \sigma(x, \cdot)$.

The term

$$\rho_0 g (h(t, x) + R(x)) \cos \theta(x) \sigma(x, -R(x)) \frac{d R(x)}{dx}$$

is also a term which takes into account the variations of the section. The contribution of this term is non-zero when:

$$\sigma(x, z = -R(x)) \neq 0,$$    (2.43)
As we have assumed that the pipe is a circular cross-section pipe, we get
\[ \int_{\Omega(t,x)} a_4 \, dydz = \int_{\Omega(t,x)} \partial_x p \, dydz = \partial_x (\rho_0 g I_1(x, A(t, x)) \cos \theta(x)) - g \rho_0 I_2(x, A) \cos \theta(x) \]  
(2.45)
in the rest of the paper.

**Computation of the term \( \int_{\Omega(t,x)} a_5 \, dydz \).** We have
\[ \int_{\Omega(t,x)} \rho_0 g z \frac{d}{dx} \cos \theta \, dydz = \rho_0 g A \frac{d}{dx} \cos \theta, \]  
(2.46)
where \( \overline{z} \) is the \( z \)-coordinate of the center of the mass. As
\[ \frac{I_1(x, A(t, x))}{A(t, x)} := \overline{y} \]
(see step “Computation of the term \( a_3 \)”), the quantity \( \overline{z} \) is related to \( I_1 \) by the formula
\[ \overline{z} = h(t, x) - \frac{I_1(x, A(t, x))}{A(t, x)}. \]  
(2.47)

**Computation of the term \( \int_{\Omega(t,x)} a_6 \, dydz \).** We have
\[ \int_{\Omega(t,x)} \rho_0 g \sin \theta \, dydz = \rho_0 g A \sin \theta. \]  
(2.48)

Then, gathering results (2.38)–(2.48), we get the equation of the conservation of the momentum.

Finally, the new shallow water equations for free surface flows in a closed water pipe with variable slope and section are
\[
\begin{aligned}
\partial_t (\rho_0 A) + \partial_x (\rho_0 Q) &= 0, \\
\partial_t (\rho_0 Q) + \partial_x \left( \frac{\rho_0 Q^2}{A} + g \rho_0 I_1 \cos \theta \right) &= -g \rho_0 A \sin \theta + g \rho_0 I_2 \cos \theta - g \rho_0 A z \frac{d}{dx} \cos \theta.
\end{aligned}
\]  
(2.49)

This model is called the FS-model.

In System (2.49), we may add a friction term \( -\rho_0 g S_f \mathbf{T} \) to take into account dissipation of energy. We have chosen this term \( S_f \) as the one given by the Manning-Strickler law (see e.g. [25]):
\[ S_f(A, U) = K(A)|U| \cdot \]

**Figure 5** The distance separating the free surface to the center of the mass of the wet section

\[ \partial_x R(x) \neq 0. \]  
(2.44)
The term \( K(A) \) is defined by
\[
K(A) = \frac{1}{K_s^2 R_h(A)^{4/3}},
\]
where \( K_s > 0 \) is the Strickler coefficient of roughness depending on the material, \( R_h(A) = A/P_m \) is the hydraulic radius and \( P_m \) is the perimeter of the wet surface area (length of the part of the channel’s section in contact with the water).

3 Formal derivation of the pressurized model

When the section is completely filled, we have to define a strategy to derive a suitable pressurized model in order to:

- take into account the compressibility of the water,
- modelize the water hammer (issuing form the overpressure and depression waves),

keeping in mind that we want to construct a mixed model which allows us to:

- deal with free surface flows,
- deal with pressurized flows, and
- cope with the transition between a free surface state and a pressurized (i.e., compressible) state transition phenomenon.

There exists a large literature on this topic, for instance:

- the Preissmann slot artefact (see, for instance, [13]), but this technique has the drawback of not taking into account the sub-atmospheric flows,
- the Allievi equations (see, for instance, [2]), but this equation is not well suited for a coupling with the derived FS-model.

Then, as a starting point, we consider the 3D isentropic compressible Euler equations:
\[
\begin{align*}
\partial_t \rho + \text{div}(\rho U) &= 0, \quad (3.1) \\
\partial_t (\rho U) + \text{div}(\rho U \otimes U) + \nabla p(\rho) &= \rho F, \quad (3.2)
\end{align*}
\]
where \( U(t,x,y,z) \) is the fluid velocity of components \((u,v,w)\) and \( \rho(t,x,y,z) \) is the volumetric mass of the fluid. The gravity source term is
\[
F = -g \begin{pmatrix} -\sin \theta(x) \\ 0 \\ \cos \theta(x) \end{pmatrix},
\]
where \( \theta(x) \) is the angle \((i,T)\) (see Figure 1 or Figure 2). As defined previously, \( T \) is the tangential vector at the point \( \omega \in \mathcal{C} \) (see Section 2 for notations), where the “pressurized” plane curve is defined below.

The system is closed by the linearised pressure law (see [25,27]):
\[
p = p_a + \frac{\rho - \rho_0}{\beta_0 \rho_0}, \quad (3.3)
\]
which has the advantage of showing clearly the overpressure state and the depression state. Indeed, \( \rho_0 \) is the volumetric mass of water, the overpressure state corresponds to \( \rho > \rho_0 \) while \( \rho < \rho_0 \) represents a depression state. The case \( \rho = \rho_0 \) is a critical one and a bifurcation point as we will see in Figure 8.

In the expression of the pressure \((3.3)\), the sound speed is defined as \( c^2 = \frac{1}{\rho_0 \beta_0} \), where \( \beta_0 \) is the compressibility coefficient of water. In practice, \( \beta_0 \) is \( 5.0 \times 10^{-10} \text{ m}^2 \text{N}^{-1} \) and thus \( c \approx 1400 \text{m} \text{s}^{-1} \).

\( p_a \) is some function and without loss of generality, it may be set to zero. Let us note that \( p_a \) plays an important role in the construction of the mixed model \( \text{PFS} \) (as we will see in Section 4).

At the wet boundary, we assume a no-leak condition and we assume that the pipe is non-deformable. Thus we have the following crucial property:
If \((x, 0, b_{sl}(x))\) is the parametric representation of the plane curve \(C_{sl}\) for free surface flows, then we define continuously the parametric representation \((x, 0, b(x))\) of the plane curve \(C_{ch}\) for pressurized flows.

As a consequence, the section \(\Omega(x)\) (in pressurized state) orthogonal to the plane curve \(C_{ch}\) is a continuous extension of the free surface one. Henceforth, we denote this curve \(C\). At a given curvilinear abscissa, at the point \(\omega \in C\), we define the pressurized section as follows:

\[
\Omega(X) = \{(Y, Z) \in \mathbb{R}^2; Z \in [-R(X), R(X)], Y \in [\alpha(X, Z), \beta(X, Z)]\}.
\]

**Remark 3.1.** As the section is non-deformable, \(\Omega(x)\) depends only on the spatial variable \(x\).

3.1 Compressible Euler equations in curvilinear coordinates

Let \((U, V, W)^T\) be the component of the fluid velocity in variables \((X, Y, Z)\) given by

\[
(U, V, W)^T = \Theta(u, v, w)^T,
\]

where \(\Theta\) is the rotation matrix generated around the axis \(j\):

\[
\Theta = \begin{pmatrix}
\cos \theta & 0 & \sin \theta \\
0 & 1 & 0 \\
-\sin \theta & 0 & \cos \theta
\end{pmatrix}.
\]

3.1.1 Transformation of the equation of conservation of the mass

Writing the equation of conservation of the mass (3.1) under a divergence form:

\[
\text{div}_{t,x,y,z} \left( \begin{array}{c}
\rho \\
\rho U
\end{array} \right) = 0,
\]

and applying Lemma 2.3, we obviously get the equations in variables \((X, Y, Z)\):

\[
\partial_t(J \rho) + \partial_X(J \rho U) + \partial_Y(J \rho V) + \partial_Z(J \rho W) = 0,
\]

where \(J\) is the determinant of the matrix \(\mathcal{A}^{-1}\) (as already defined by (2.29)).

**Remark 3.2.** Let us also remark that, from (H), we have \(J(X, Z) > 0\).

3.1.2 Transformation of the equation of conservation of the momentum

Following Subsection 2.1, namely:

- using Lemma 2.3,
- multiplying the equation of conservation of the momentum (3.2) on the left by the matrix \(J\Theta\),

we get the equation for \(U\) in the variables \((X, Y, Z)\):

\[
\partial_t(J \rho U) + \partial_X(J \rho U^2) + \partial_Y(J \rho UV^2) + \partial_Z(J \rho UW) + \partial_X p = -\rho J g \sin \theta(X) + \rho UW \frac{d}{dX} \cos \theta(X).
\]

Other equations are unused since we want to derive a unidirectional model. Let us also note, in the derivation of the \(\text{FS}\)-model, all these equations were relevant to get the expression of the pressure.
3.1.3 Formal asymptotic analysis

As in Subsection 2.1.3, we write the non-dimensional version of equations (3.5)–(3.6) with respect to the small parameter $\varepsilon$ already introduced. In particular, we seek an approximation at main order with respect to the asymptotic expansion with respect to $\varepsilon$. As pointed out before, we will get $J \approx 1$, where $J$ is the determinant of the Jacobian matrix of the change of variables.

Let us recall that

$$
\frac{1}{\varepsilon} = \frac{L}{H} = \frac{L}{T} = \frac{U}{V} = \frac{V}{W}
$$

is assumed to be large enough, where $H$, $L$ and $l$ are characteristic length of the height, the length, and the width (where $l = H$ since we deal with only circular cross-section pipe) and $U$, $V$ and $W$ are characteristic speed following the main axis, the normal direction and the bi-normal one, respectively. Then, let $T$ be a characteristic time such that

$$
\frac{U}{T}.
$$

We set the non-dimensional variables:

$$
\tilde{U} = \frac{U}{U}, \quad \tilde{V} = \varepsilon \frac{V}{U}, \quad \tilde{W} = \varepsilon \frac{W}{U}, \quad \tilde{X} = \frac{X}{L}, \quad \tilde{Y} = \frac{Y}{H}, \quad \tilde{Z} = \frac{Z}{H}, \quad \tilde{\rho} = \frac{\rho}{\rho_0}, \quad \tilde{\theta} = \theta.
$$

With these notations, the non-dimensional equations (3.5)–(3.6) are:

$$
\begin{cases}
\begin{aligned}
\partial_t (\tilde{\rho} \tilde{U}) + \partial_{\tilde{X}} (\tilde{\rho} \tilde{U} \tilde{U}) + \partial_{\tilde{Y}} (\tilde{\rho} \tilde{U} \tilde{V}) + \partial_{\tilde{Z}} (\tilde{\rho} \tilde{U} \tilde{W}) &= 0, \\
\partial_t (\tilde{\rho} \tilde{V} \tilde{U}) + \partial_{\tilde{X}} (\tilde{\rho} \tilde{V} \tilde{U} \tilde{U}) + \partial_{\tilde{Y}} (\tilde{\rho} \tilde{V} \tilde{U} \tilde{V}) + \partial_{\tilde{Z}} (\tilde{\rho} \tilde{V} \tilde{U} \tilde{W}) + \frac{1}{M_a^2} \partial_{\tilde{X}} \tilde{\rho} &= 0,
\end{aligned}
\end{cases}
$$

(3.7)

where $F_{r,M} = \frac{U}{\sqrt{g_\bar{\rho} \bar{d}}}$ is the Froude number and $M_a = \frac{U}{c}$ is the Mach number.

Formally, taking $\varepsilon = 0$, the previous equations (3.7) read:

$$
\begin{cases}
\begin{aligned}
\partial_t (\tilde{\rho} \tilde{U}) + \partial_{\tilde{X}} (\tilde{\rho} \tilde{U} \tilde{U}) + \partial_{\tilde{Y}} (\tilde{\rho} \tilde{U} \tilde{V}) + \partial_{\tilde{Z}} (\tilde{\rho} \tilde{U} \tilde{W}) &= 0, \\
\partial_t (\tilde{\rho} \tilde{V} \tilde{U}) + \partial_{\tilde{X}} (\tilde{\rho} \tilde{V} \tilde{U} \tilde{U}) + \partial_{\tilde{Y}} (\tilde{\rho} \tilde{V} \tilde{U} \tilde{V}) + \partial_{\tilde{Z}} (\tilde{\rho} \tilde{V} \tilde{U} \tilde{W}) + \frac{1}{M_a^2} \partial_{\tilde{X}} \tilde{\rho} &= 0,
\end{aligned}
\end{cases}
$$

(3.8)

(3.9)

$$
\begin{align}
\frac{-\tilde{\rho} \sin \tilde{\theta} (\tilde{X})}{F_{r,M}^2} - \frac{\tilde{Z}}{F_{r,H}^2} \frac{d}{dX} \cos \tilde{\theta} (\tilde{X}) &= 0.
\end{align}
$$

(3.10)

Henceforth, we denote $(x, y, z)$ the dimensioned variables $(X, Y, Z)$, and $(u, v, w)$ the dimensioned speed $(\tilde{U}, \tilde{V}, \tilde{W})$. Setting

$$
x = L \tilde{X}, \quad y = H \tilde{Y}, \quad z = H \tilde{Z},
$$

$$
u = \tilde{U}, \quad v = \varepsilon \tilde{U}, \quad w = \varepsilon \tilde{U}, \quad \rho = \tilde{\rho},
$$

we finally get the following equations written in the curvilinear variables:

$$
\begin{align}
\partial_t \rho + \partial_x (\rho u) + \partial_y (\rho v) + \partial_z (\rho w) &= 0, \quad (3.11) \\
\partial_t (\rho u) + \partial_x (\rho u^2) + \partial_y (\rho uv) + \partial_z (\rho uw) + \partial_z \rho &= -g \rho \sin \theta (x) - g \rho \frac{d}{dx} \cos \theta (x), \quad (3.12)
\end{align}
$$

where $\rho$ is the linearised pressure law given by (3.3).

**Remark 3.3.** The previous equations are the hydrostatic approximation of the Euler compressible equations, where we have neglected the second and third momentum equations.
3.1.4 Vertical averaging of the hydrostatic approximation of Euler equations

The physical section of water, \( S(x) \), and the discharge, \( Q(t, x) \), are respectively defined by

\[
S(x) = \int_{\Omega(t, x)} dydz, \tag{3.13}
\]

and

\[
Q(t, x) = S(x)\overline{\omega}(t, x), \tag{3.14}
\]

where \( \overline{\omega} \) is the mean speed over the section \( \Omega(x) \):

\[
\overline{\omega}(t, x) = \frac{1}{S(t, x)} \int_{\Omega(t, x)} u(t, x, y, z) dydz. \tag{3.15}
\]

Let \( \mathbf{m} \in \partial\Omega(x) \). We denote by \( \mathbf{n} = \frac{\mathbf{m}}{|\mathbf{m}|} \) the outward unit normal vector to the boundary \( \partial\Omega(x) \) at the point \( \mathbf{m} \) in the \( \Omega \)-plane and \( \mathbf{m} \) stands for the vector \( \omega \mathbf{m} \) (cf. Figure 3).

Following the section-averaging method performed to obtain the FS-model, we integrate Systems (3.11)–(3.12) over the cross-section \( \Omega \). Noting the averaged values over \( \Omega \) by the overlined letters (except for \( \overline{\omega} \)), and using the approximations \( \overline{\omega} \approx \overline{\rho} \overline{\omega}, \overline{\rho}^2 \approx \overline{\rho}^2 \), we get the following shallow water like equations:

\[
\begin{aligned}
\partial_t (\overline{\rho} S) + \partial_x (\overline{\rho} S \overline{\omega}) &= \int_{\partial\Omega(x)} \rho \left( u \partial_x \mathbf{m} - \mathbf{V} \right) \cdot \mathbf{n} ds, \tag{3.16}
\end{aligned}
\]

\[
\begin{aligned}
\partial_t (\overline{\rho} S \overline{\omega}) + \partial_x (\overline{\rho} S \overline{\omega}^2 + c^2 \overline{\rho} S) &= -g \overline{\rho} S \sin \theta + c^2 \overline{\rho} S \frac{dS}{dx} - g \overline{\rho} S \overline{\omega} \frac{d}{dx} \cos \theta \\
&\quad + \int_{\partial\Omega(x)} \rho u \left( u \partial_x \mathbf{m} - \mathbf{V} \right) \cdot \mathbf{n} ds, \tag{3.17}
\end{aligned}
\]

where \( \mathbf{V} = (v, w)^T \) is the velocity field in the \( (N, B) \)-plane. The integral terms appearing in (3.16) and (3.17) vanish, as the pipe is infinitely rigid, i.e., \( \Omega = \Omega(x) \) (see [7] for more details about deformable pipes). The non-penetration condition (see Figure 6) follows:

\[
\begin{pmatrix}
u \\
w
\end{pmatrix}. \mathbf{n}_{wb} = 0.
\]

Omitting the overlined letters (except for \( \overline{\omega} \)), setting the conservative variables

\[
A = \frac{\rho}{\rho_0} S, \quad \text{the FS equivalent wet area,} \tag{3.18}
\]

\[
Q = A U, \quad \text{the FS equivalent discharge,} \tag{3.19}
\]

and dividing Equations (3.16)–(3.17) by \( \rho_0 \), adding on each side of the equation (3.17) the quantity \(-c^2 \frac{dS}{dx}\), we get the pressurized model, called the P-model:

\[
\begin{aligned}
\partial_t A + \partial_x Q &= 0, \\
\partial_t Q + \partial_x \left( \frac{Q^2}{A} + c^2 (A - S) \right) &= -g A \sin \theta + c^2 \left( \frac{A}{S} - 1 \right) \frac{dS}{dx} - g A \overline{\omega} \frac{d}{dx} \cos \theta. \tag{3.20}
\end{aligned}
\]

Remark 3.4. In terms of area, a depression occurs when \( A < S \) (i.e., \( \rho < \rho_0 \)) and an overpressure occurs if \( A > S \) (i.e., \( \rho > \rho_0 \)).

As introduced previously for the FS-model, we may introduce the friction term \(-\rho g S f T\) given by the Manning-Strickler law (see e.g. [25]):

\[
S_f(S, U) = K(S)U|U|,
\]
where $K(S)$ is defined by
\[
K(S) = \frac{1}{K_s^2 R_h(S)^{4/3}},
\]
where $K_s > 0$ is the Strickler coefficient of roughness depending on the material and $R_h(S) = S/P_m$ is the hydraulic radius, where $P_m$ is the perimeter of the wet surface area (the length of the part of the channel’s section in contact with the water, equal to $2\pi R$ in the case of circular pipe).

### 4 The PFS-model

In the previous sections, we have proposed two models: one for the free surface flows and the other for pressurized (compressible) flows which are very close to each other. In this section, we are motivated to connect “continuously” these two models through the transition points. Let us recall these two models.

**The FS-model.**

\[
\begin{aligned}
&\partial_t A_{st} + \partial_x Q_{st} = 0, \\
&\partial_t Q_{st} + \partial_x \left( \frac{Q_{st}^2}{A_{st}} + p_{st}(x, A_{st}) \right) = -gA_{st} \frac{dZ}{dx} + \Pr_{st}(x, A_{st}) - gA_{st} z \frac{d}{dx} \cos \theta - gK(x, A_{st}) \frac{Q_{st} |Q_{st}|}{A_{st}},
\end{aligned} \tag{4.1}
\]

where
\[
p_{st}(x, A_{st}) = gI_1(x, A_{st}) \cos \theta,
Pr_{st}(x, A_{st}) = gI_2(x, A_{st}) \cos \theta,
K(x, A_{st}) = \frac{1}{K_s^2 R_h(A_{st})^{4/3}},
\]

with $I_1$ and $I_2$ being defined by (2.41) and (2.42).

**The P-model.**

\[
\begin{aligned}
&\partial_t A_{ch} + \partial_x Q_{ch} = 0, \\
&\partial_t Q_{ch} + \partial_x \left( \frac{Q_{ch}^2}{A_{ch}} + p_{ch}(x, A_{ch}) \right) = -gA_{ch} \frac{dZ}{dx} + \Pr_{ch}(x, A_{ch}) - gA_{ch} z \frac{d}{dx} \cos \theta - gK(x, S) \frac{Q_{ch} |Q_{ch}|}{A_{ch}},
\end{aligned} \tag{4.2}
\]

where
\[
p_{ch}(x, A_{ch}) = c^2 (A_{ch} - S),
Pr_{ch}(x, A_{ch}) = c^2 \left( \frac{A_{ch}}{S} - 1 \right) \frac{dS}{dx},
K(x, S) = \frac{1}{K_s^2 R_h(S)^{4/3}}.
\]

We remark that the terms $\frac{dZ}{dx}$, $z \frac{d}{dx} \cos \theta$ and the friction are similar in both models (where we set $Z(x) = b(x)$).

**Remark 4.1.** The plane curve, with parametrization $(x, 0, b(x))$ is chosen as the main pipe axis in the axis-symmetric case. Actually, this choice is more convenient for pressurized flows while the bottom line is adapted to free surface flows. Thus, we must assume small variations of the section ($S$’ small) or equivalently small angle $\varphi$ as displayed in Figure 6 in order to keep a continuous connection of the term $Z(x)$ from one to another type of flows.
The real difference between these two models is mainly due to the pressure law: one is of “acoustic” type while the other is hydrostatic. We are then motivated by defining a suitable couple of “mixed” variables in order to connect “continuously” these two models through the transition points. But, necessarily, the gradient of flux of the new system will be discontinuous at transition points, due to the difference of sound speed (as we will see below).

To this end, we introduce a state indicator $E$ (see Figure 8) such that:

$$E = \begin{cases} 
1, & \text{if the state is pressurized: } (\rho \neq \rho_0), \\
0, & \text{if the state is free surface: } (\rho = \rho_0). 
\end{cases} \quad (4.3)$$

Next, we define the physical wet area $S$ by

$$S = S(A, E) = \begin{cases} 
S, & \text{if } E = 1, \\
A, & \text{if } E = 0. 
\end{cases} \quad (4.4)$$

We then introduce a couple of variables, called “mixed variables”:

$$A = \frac{\rho}{\rho_0} S, \quad (4.5)$$
$$Q = A u, \quad (4.6)$$

which satisfy the following conditions:

- if the flow is free surface, $\rho = \rho_0$, $E = 0$ and consequently $S = A$, and
- if the flow is pressurized, $\rho \neq \rho_0$, $E = 1$ and consequently $S = S$.

To construct a “mixed” pressure law (cf. Figure 8), we set

$$p(x, A, E) = c^2 (A - S) + g I_1(x, S) \cos \theta, \quad (4.7)$$

where the term $I_1$ is given by

$$I_1(x, S) = \int_{-R(x)}^{\mathcal{H}(S)} (\mathcal{H}(S) - z) \sigma(x, z) dz \quad (4.8)$$

with $\mathcal{H}$ representing the $z$-coordinate of the water level:

$$\mathcal{H} = \mathcal{H}(S) = \begin{cases} 
h(A), & \text{if } E = 0, \\
R(x), & \text{if } E = 1. 
\end{cases} \quad (4.9)$$

Figure 6  Some restriction concerning the geometric domain: $\varphi < \theta$
Figure 7  Pressure law in the case of pipe with circular section

Thus, the constructed pressure is continuous throughout the transition points:

$$\lim_{A \rightarrow S} p(x, A, E) = \lim_{A \rightarrow S} p(x, A, E)$$

but its gradient is discontinuous (cf. Figure 7):

$$\frac{\partial p}{\partial A}(x, A, 0) = \sqrt{\frac{gA}{T}} \neq c^2 = \frac{\partial p}{\partial A}(x, A, 1).$$

Remark 4.2. The transition point ($\rho = \rho_0$) is then a bifurcation point.

From the FS-model (4.1), the P-model (4.2), the “mixed” variables (4.5)–(4.6), the state indicator $E$ (4.3), the physical height of water $S$ (4.4) and the pressure law (4.7), we can define the PFS-model (Pressurized and Free Surface) for unsteady mixed flows in closed water pipes with variable section and slope, as follows:

$$\begin{align*}
\frac{\partial t}{\partial A} + \frac{\partial x}{\partial Q} &= 0, \\
\frac{\partial t}{\partial Q} + \frac{\partial x}{\partial \left(\frac{Q^2}{A} + p(x, A, E)\right)} &= -gA \frac{dZ}{dx} + Pr(x, A, E) - G(x, A, E) - K(x, A, E)Q \left|\frac{Q}{A}\right|,
\end{align*}$$

(4.10)

where $Pr, K$, and $G$ represent respectively the pressure source term, the curvature term and the friction:

$$Pr(x, A, E) = c^2 \left(\frac{A}{S} - 1\right) \frac{dS}{dx} + gI_2(x, S) \cos \theta$$

with $I_2(x, S) = \int_{R(z)}^H(z) (H(z) - z) \partial_x \sigma(x, z) dz$,

$$G(x, A, E) = gA \pi(x, S) \frac{d}{dx} \cos \theta,$$

$$K(x, A, E) = \frac{1}{K^2 R_h(S)^{4/3}}.$$
Figure 8  Free surface state \( p(X, A, 0) = g I_1(X, A) \cos \theta \) (top), pressurized state with overpressure \( p(x, A, 1) > 0 \) (bottom left), pressurized state with depression \( p(x, A, 1) < 0 \) (bottom right)

Remark 4.4. We have seen that when the flow is fully pressurized, the overpressure states are reported when \( A > S \) and depression states when \( A < S \). However, when the flow is mixed and \( A < S \), we do not know a priori if the state is free surface or pressurized. Therefore, the indicator state \( E \) is there to overcome this difficulty. Thus, combining this with a discrete algorithm on \( E \) is useful to describe both depression areas and free surface ones. When \( A > S \), without any ambiguity, the pressurized state is proclaimed. From a numerical point of view, the transition points between two types of flows are treated as a free boundary, corresponding to the discontinuity of the gradient of the pressure (for more details, see [5,16]).

The PFS-model (4.10) satisfies the following properties:

**Theorem 4.5.** 1) The right eigenvalues of System (4.10) are given by

\[
\lambda^- = u - c(A, E), \quad \lambda^+ = u + c(A, E),
\]

with

\[
c(A, E) = \begin{cases} 
\sqrt{\frac{g}{T(A)}} A \cos \theta, & \text{if } E = 0, \\
c, & \text{if } E = 1.
\end{cases}
\]

Then, System (4.10) is strictly hyperbolic on the set

\[
\{A(t, x) > 0\}.
\]

2) For smooth solutions, the mean velocity \( u = Q/A \) satisfies

\[
\partial_t u + \partial_x \left( \frac{u^2}{2} + c^2 \ln(A/S) + gH(S) \cos \theta + gZ \right) = -gK(x, A, E)u|u| \leq 0.
\]

(4.11)
The quantity
\[ \frac{u^2}{2} + c^2 \ln(A/S) + gH(S) \cos \theta + gZ \]
is called the total head.

3) The still water steady state reads
\[ u = 0 \quad \text{and} \quad c^2 \ln(A/S) + gH(S) \cos \theta + gZ = \text{cte.} \quad (4.12) \]

4) It admits a mathematical entropy
\[ \mathcal{E}(A, Q, E) = \frac{Q^2}{2A} + c^2 A \ln(A/S) + c^2 S + gA\overline{\tau}(x, S) \cos \theta + gAZ, \quad (4.13) \]
which satisfies the entropy relation for smooth solutions
\[ \partial_t \mathcal{E} + \partial_x ((\mathcal{E} + p(x, A, E))u) = -gAK(X, A, E) u^2|u| \leq 0. \quad (4.14) \]

Notice that the total head and \( \mathcal{E} \) are defined continuously through the transition points.

Remark 4.6. The term \( A \overline{\tau}(x, A)(\cos \theta)' \) is also called “corrective term” since it allows us to write the equations (4.11) and (4.14) with (4.13).

Proof of Theorem 4.5. The results (4.11) and (4.14) are obtained in a classical way. Indeed, Equation (4.11) is obtained by subtracting the result of the multiplication of the mass equation by \( u \) to the momentum equation. Then multiplying the mass equation by
\[ \left( \frac{u^2}{2} + c^2 \ln(A/S) + gH(S) \cos \theta + gZ \right) \]
and adding the result of the multiplication of Equation (4.11) by \( Q \), we get:
\[ \partial_t \left( \frac{Q^2}{2A} + c^2 A \ln(A/S) + c^2 S + gA\overline{\tau}(x, S) \cos \theta + gAZ \right) \]
\[ + \partial_x \left( \left( \frac{Q^2}{2A} + c^2 A \ln(A/S) + c^2 S + gA\overline{\tau}(x, S) \cos \theta + gAZ + p(x, A, E) \right) u \right) + c^2 \left( A \frac{1}{S} - 1 \right) \partial_t S \]
\[ = -gAK(x, A, E) u^2|u| \leq 0. \]
We see that the term \( c^2 \left( A \frac{1}{S} - 1 \right) \partial_t S \) is identically 0 since we have \( S = A \) when the flow is free surface whereas \( S = S(x) \) when the flow is pressurized. Moreover, from the last inequality, when \( S = A \), we have the classical entropy inequality (see [6, 7]) with \( \mathcal{E} \):
\[ \mathcal{E}(A, Q, E) = \frac{Q^2}{2A} + gA\overline{\tau}(x, A) \cos \theta + gAZ, \]
while in the pressurized case, it is
\[ \mathcal{E}(A, Q, E) = \frac{Q^2}{2A} + c^2 A \ln(A/S) + c^2 S + gAZ. \]
Finally, the entropy for the PFS-model reads
\[ \mathcal{E}(A, Q, E) = \frac{Q^2}{2A} + c^2 A \ln(A/S) + c^2 S + gA\overline{\tau}(X, S) \cos \theta + gAZ. \]
Let us remark that the term \( c^2 S \) makes \( \mathcal{E} \) continuous through transition points us and it permits also to write the entropy flux under the classical form \((\mathcal{E} + p)u\).
5 Perspectives

In view of the difference of sound speed \((c \approx 1400 \text{ ms}^{-1} \text{ for a pressurized state and } c \approx 1 \text{ ms}^{-1} \text{ for a free surface state})\), the gradient of the pressure, thus the flux of the PFS equations, is discontinuous throughout the transition points. More generally, these equations belong to a class of hyperbolic systems of conservation laws with discontinuous gradient, especially a generalization of equations coupled through a fixed discontinuity (see [20,22,23] with the classical example of the Lighthill-Whitham-Richards model for road traffic) since, in the present case, the discontinuity is mobile. It is then an interesting and difficult problem because of the definition of the solution associated with the Riemann problem. In general, given two initial states which are not connected by a shock wave, there exist an infinite number of paths to connect them through the interface. For instance, in Boutin’s thesis [9], he defined paths using physical criteria that enable one to extract the solution. To our knowledge, up to date, there are no results for the mobile discontinuities and the PFS-model is a nice example of such an open problem. However, in each region where the gradient of the flux is continuous, the solution is constructed in a classical way (see, for example, [26]).
