Abstract

Aim: This systematic review aimed to compare different attachment systems used in mandibular implant supported overdentures by assessing outcomes such as prosthodontic maintenance and complication, peri implant tissue changes, retention, and patient satisfaction for optimum selection of attachment system.

Settings and Design: This systematic review conducted following Preferred Reporting Items for the Systematic Review and Meta Analysis (PRISMA) guidelines.

Materials and Methods: A systematic electronic literature search was conducted through PubMed, The Cochrane Central Register of Controlled Trials (Central), and Science direct. A hand search was also performed for individual journals and reference lists of selected studies. Randomized controlled clinical trials and crossover clinical trials from 2010 to 2020 with follow up of more than 1 year were included. The Cochrane Collaboration’s tool was used for assessing the risk of bias of included studies.

Statistical Analysis Used: The statistical meta analysis was performed using Review Manager (RevMan) [computer program]. Version 5.4. Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2020.

Results: Six studies that met the inclusion criteria possess the low risk of bias with follow up of more than 1 year were included in this systematic review. Out of four outcomes, meta analysis was performed for prosthodontic maintenance and peri implant tissue changes. Due to the limited availability of data, retention and patient satisfaction were reviewed systematically without meta analysis. The result of meta analysis for ball versus magnet attachment showed statistically significant differences in prosthodontic complications and maintenance, and ball attachment reported fewer complications than the locator attachment (risk ratio [RR] = 0.55, confidence interval [CI] = 95%, P = 0.03). Peri implant tissue changes were analyzed in the included studies as probing depth and marginal bone loss. The result of meta analysis for probing depth showed no statistically significant difference between bar versus telescopic type of attachment (RR = 0.20, CI = 95%, P = 0.74). The meta analysis results for marginal bone loss showed no statistically significant difference between bar versus telescopic type of attachment (mean difference = 0.35, CI = 95%, P = 0.10).

Conclusion: It can be concluded from the current review that bar attachment provided the most superior retention. The telescopic attachment system not only showed the most favorable patient’s satisfaction but also reported the least peri implant mucosal changes. The ball attachment system is a favorable choice for limited inter arch space and parallel implant placement.

Keywords: Edentulous mandible, implant overdenture, overdenture attachment systems, patient’s satisfaction, peri-implant tissue changes, prosthodontic complication and maintenance, retention

INTRODUCTION

Edentulism is a debilitating and irreversible condition of sustained significance and prevalence in the aged population. Adaptation to wearing complete dentures is complex and must be considered from various standpoints. Primary treatment options can be either conventional removable complete denture or implant-supported fixed or removable prosthesis for a completely edentulous patient. Conventional complete dentures more often cause difficulties in chewing and speaking because of poor retention, stability, support, and various other factors. Dental implants to replace natural teeth have become a common practice in restorative and surgical dentistry. Implants provide excellent support for fixed and removable prostheses, which increases functional efficiency compared with conventional removable complete and partial denture prostheses and restores the esthetics of the patients. Rehabilitation with dental implants is considered to be the successful option of the edentulous arch, so it can be said that any edentulous area is a potential implant site.

Implant overdenture has become the more successful option for completely edentulous arch rehabilitation. Broadly overdenture attachment systems are divided into four main categories: Ball or stud, bar and clip, magnet type, and telescopic attachments. Each attachment system having a retainer consisting of the metal receptacle (the female or matrix) and a closely fitting part (the male or patrix), where one component is embedded within the undersurface of the prothesis, and the other is connected to the implant.

Prosthetic maintenance and complications associated with different overdenture attachment systems are various such as matrix looseness, detachment of matrix, fracture of a denture, need for relining and rebasing, fracture of components such as bar fracture, crown fracture, etc. Furthermore, the retention provided by various overdenture attachment systems is varied. Sometimes prosthesis retention is too high may cause problems in insertion and removal of the prosthesis. Effect on peri-implant tissue condition such as plaque and calculus deposition, gingivitis, probing depth, marginal bone loss are also noteworthy complications associated with different attachment systems. Patient satisfaction is an important consideration, which can be affected by prosthesis maintenance, stability and retention of the prosthesis, and the prosthesis’s ability to function properly. These factors collectively decide the success of prostheses.

Several studies compare the different factors such as prosthodontic maintenance and complications, retention, effect on peri-implant tissue condition, patient’s satisfaction, masticatory effectiveness, the cost-effectiveness of the various overdenture attachment systems for maxillary, mandibular implant overdenture.

A systematic assessment published by Ha-young Kim et al. in 2012 compared the implant survival rate, prosthetic maintenance and complications, and patient satisfaction of various attachment systems. In this systematic review, authors have included studies up to August 2010. The evolution of the overdenture attachment system is continuously ongoing to overcome the problems associated with prostheses. Various newer attachment systems have been introduced in the field with improvements in the bar, ball, telescopic, and magnetic attachments that claim to have minimum prosthesis complications, making clinicians confuse to select one for the best clinical outcome. Thus, the main purpose of this systematic review and meta-analysis was to compare studies from 2010 to 2020 for the comparison of various outcomes of newly marketed overdenture attachment systems.

The aim of this systematic review was to answer the PICOTS question: “In completely edentulous mandibular arch rehabilitated with late implant placement and delayed loading protocols, do the prosthodontic complication, retention, peri-implant tissue changes and patient’s satisfaction vary with various implant overdenture attachment systems?”

METHODS

This systematic review was performed according to the Preferred Reporting Items for the Systematic Review and Meta-Analysis guidelines.

Randomized controlled clinical trials (RCTs) and crossover clinical trials with at least 1 year of follow-up on attachment systems for two or more implant-supported mandibular overdentures, reporting various outcomes such as prosthodontic maintenance/complications, patient’s satisfaction, prosthesis retention, and peri-implant tissue evaluation were included in this systematic review.

The PICOTS format provided by the Centre For Evidence-Based Medicine for systematic literature search to answer the research question was formulated as below,

P - POPULATION: Patients having completely edentulous mandibular arch.

I - INTERVENTION: Late implant placement (minimum two implants in interferamina region) and delayed loading with implant-supported overdenture.
C - COMPARISON: Various overdenture attachment systems like ball attachment, bar attachment, magnet attachment, telescopic type of attachment.

O - OUTCOME:
1. Prosthodontic maintenance and complications
2. Retention
3. Effect on peri-implant tissue condition and
4. Patient’s satisfaction.

T - TIME - Studies published from 2010 to 2020, with the minimum follow-up of 1 year.

S - STUDY DESIGN: Prospective RCT and crossed over clinical trial.

Search strategy
An electronic literature search was independently conducted by two investigators (PS, PM) from January 2010 to December 2020, using MEDLINE (PubMed), the Cochrane central register of controlled trials (central) and Science direct databases for articles in English language published in journals of dentistry using following search terms: “implant overdenture AND mandibular arch,” “mandibular implant overdenture AND overdenture attachment systems,” “implant overdenture attachments NOT maxillary implant overdenture,” “implant overdenture attachment systems NOT single implant overdenture,” “mandibular implant overdenture AND implant overdenture attachment systems NOT maxillary implant overdenture NOT single implant overdenture,” “mandibular implant overdenture attachments AND prosthodontic complication/maintenance,” “mandibular implant overdenture attachments AND retention,” “mandibular implant overdenture attachments AND patient’s satisfaction,” “mandibular implant overdenture attachments AND peri-implant tissue condition.”

The following journals were also searched manually: The Journal of the Indian Prosthodontic Society, The Journal of Prosthetic Dentistry, International Journal of Prosthodontics, The Journal of Advanced Prosthodontics, International Journal of Oral and Maxillofacial Implants, Clinical Oral Implants Research, Journal of Oral Implantology, British Dental Journal, Journal of Oral Rehabilitation, Journal of Dental Research.

Study selection and intervention

Inclusion criteria
Articles that met the following inclusion criteria were included in this systematic review:
1. RCTs and cross-over clinical trials published only in the English language
2. Mandibular complete edentulous arch
3. Overdenture retained with two or more interforaminal implants
4. Late implant placement delayed loading protocol
5. Studies included from 2010 to 2020
6. Overdenture attachments placed on root-form endosseous implants
7. Follow-up period of a minimum of 1 year.

Exclusion criteria
Studies meeting the following criteria were excluded:
1. Rehabilitation of partially edentulous arches with implant-supported overdentures
2. Studies with follow-up of <1 year
3. Immediate implant placement with immediate loading
4. Studies including overdenture implant attachment in the maxillary arch.
5. Nonclinical studies, reviews, papers without abstracts, case reports/series, letters to editors, and technical notes
6. Single implant-supported overdentures.

Data extraction and collection
The full-text copies of all potential articles were independently evaluated by two authors (PS, PM). The data were recorded as per the following criteria.
1. Name of the author
2. Publication year
3. Type of implant placement
4. Number of implant placement
5. Area of implant placement
6. Implant with delayed loading
7. Overdenture for mandibular arch
8. Type of attachments for overdenture
9. Outcome assessment
10. Follow-up period
11. Type of study (RCT and crossover clinical trial).

Selection of studies
The data extraction was once carried out independently by two investigators (PS, PM), and duplicates were eliminated by using Mendeley software and after that discussed to discover an agreement. The titles and abstracts of all studies identified through the electronic searches were scanned independently by four investigators (PS, UH, PM, SR). For articles that met the inclusion criteria or for which there was inadequate information in the title and abstract to make a clear decision, the full report was obtained. The full reports obtained from all the electronic and other strategies of searching were assessed independently by four investigators (PS, UH, PM, SR) to set up whether the studies did meet the inclusion criteria.
or not. Disagreements were resolved by discussion. A fifth and sixth (SP, SH) review authors were consulted where a resolution was not possible. All studies meeting the inclusion criteria then underwent validity assessment and data extraction.

Assessment of risk of bias in included studies
Four investigators (SP, SH, PS, UH) independently assessed the risk of bias for each study using the standard guideline outlined in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011). There were no disagreements for the assessment of the risk of bias in the present study.

The Cochrane collaboration’s tool, for author’s judgments, were categorized on the study methods as “Low risk,” “High risk,” or “Unclear risk” of bias-related for following domains:
1. Random sequence generation (checking for possible selection bias)
2. Allocation concealment (checking for possible selection bias)
3. Blinding of participants and personnel (checking for possible performance bias)
4. Blinding of outcome assessment (checking for possible detection bias)
5. Incomplete outcome data (checking for possible attrition bias due to the amount, nature and handling of incomplete outcome data)
6. Selective reporting (checking for reporting bias)
7. Other bias (checking for bias due to problems not covered by the previously mentioned domains).

Measures of treatment effect
Based on the Review Manager software 2014, all the statistical tests were performed. For dichotomous data, results were presented as summary risk ratio (RR) together with 95% confidence intervals (CIs).

Continuous data
For continuous data, the mean difference (MD) was used with 95% CI.

RESULTS

Results of search
A total of 235 studies were identified from all search data sources, using search terms “mandibular implant overdenture AND overdenture attachment system.” After using Boolean operator “NOT” “single implant overdenture,” 21 studies were excluded from the total search. And further search from studies from 2010 to 2020, another 92 studies were excluded, and a total of 122 full-text articles were assessed. Based on exclusion criteria, the systematic review, case reports, narrative review, in vitro study, and other nonrelevant studies were excluded, and the final 20 studies were found eligible for further evaluation. Based on exclusion criteria, studies including overdenture for both maxillary and mandibular implant overdenture, studies including both single and multiple implant overdentures, and overdentures supported with immediately loading implants were excluded. In this systematic review, final six studies that met the inclusion criteria were included [Figure 1].

Characteristics of included studies
Six trials were eligible to be included [15-20] [Table 1].

The quality assessment (risk of bias)
As per the Cochrane collaboration’s tool, author judgment on the study methods was categorized as “low risk,” “high risk,” or “unclear risk” of bias.

Risk of bias in included studies
Detailed descriptions of the risk of bias in the included trials have been provided in the “Risk of bias” figures, as shown in Figures 2 and 3.

Meta-analysis
Analysis 1
A RCT compared ball attachment and locator attachment for prosthodontic maintenance, patient’s preference, biologic complications, and oral health-related quality of life.

This study provided data for analysis only about prosthodontic maintenance. Upon pooling the data obtained from this single trial regarding the outcome prosthodontic success, it was identified that ball attachment reported fewer complications compared to the locator attachment (RR = 0.55, CI = 95%, P = 0.03, Heterogeneity = not applicable, single study, 48 Patients, 24 events of prosthodontic complications) [Figure 4].

Another study that compared the milled bar and telescopic attachment provided data for evaluating peri-implant parameters (probing depth and bone loss).

Analysis 2-for probing depth
Upon pooling the data obtained from this single study, the milled bar and telescopic attachment results were almost similar, with 0.2 mm less probing depth observed in the milled bar (RR = 0.20, CI = 95%, heterogeneity = not
applicable, \( P = 0.74, Z = 0.33, \) single study, total patient = 45) [Figure 5].

Analysis 3-for bone loss
Furthermore, it was identified that milled bar and telescopic type of attachment showed almost similar peri-implant bone loss (MD = 0.35, CI = 95\%, heterogeneity = not applicable, \( P = 0.10, \) total patient = 45, one study, \( Z = 1.65 \)) [Figure 6].

**DISCUSSION**

Implant overdenture can be an optimum choice for completely edentulous patients, who cannot opt for fixed implant prosthesis due to compromised posterior bone quality, anatomical limitations, increased treatment cost, and systemic medical conditions.\(^{[21-23]}\)

For the completely edentulous mandible, the two-implant-supported overdenture should become the first treatment choice according to the statement given by McGill consensus.\(^{[24]}\) The selection of attachment type depends on various factors such as bone height, bone width, inter-arch space, degree of retention required, patient’s economic condition, patient’s prosthetic
expectation, and preference by the clinician. Minimum space available for rehabilitation between the mandibular incisal edge to mucosa should be 13–14 mm for bar attachment, 13–14 mm for telescopic attachment, 10–12 mm for ball attachment, 8.5 mm for locator attachment, and 8.5 mm for magnet attachment. Angulation in between the implants of 10 degree or less is well tolerated by ball attachment. While angulations up to 40 degree are easily compensated using locator attachment. The parallelism of implants plays a very crucial role while using the telescopic attachment. However, bar attachment can manage nonparallelism using angulated abutments. However, the implant-supported overdenture is associated with frequent follow-up visits, prosthetic failure, overdenture attachment loosening, peri-implant soft and hard tissue complications. Depending on the attachment, these complications may vary in their presentations.

Hence, the purpose of this systematic review and meta-analysis was to evaluate how various mandibular implant overdenture attachment systems differ in retention, prostodontic maintenance, their effect on peri-implant tissue health and overall patient’s satisfaction.
Ball attachment was documented to be the most frequently used attachment in the included studies. Two studies compared the ball attachment with locator attachment and reported that ball attachment was more retentive than locator attachment based on patient perception. An *in vitro* study reported that locator attachment showed the least amount of retention (33.5 ± 9.77 N) compared to the ball (40.3 ± 15.83 N) and bar attachments (46.9 ± 13.9 N). When compared to bar attachment, ball attachment showed the same amount of stability (18–20 N) as the bar attachment when measured with force gauge, irrespective of the number of implants used. It was documented that the ball attachment required more prosthetic maintenance compared to the locator, magnet, and telescopic attachments. Whereas, Kleis *et al.* reported that locator attachment required frequent follow visits. This result is consistent with a systematic review reported by Miler AM *et al.*, which also concluded that the nylon ring of the male component of locator attachment required frequent replacement visits. Optimum peri-implant tissue health was maintained using a ball and telescopic attachment systems. The highest level of patient satisfaction was acquired on using telescopic attachment followed by ball and bar attachments.

Naert *et al.* compared splinted bar attachment with unsplinted ball and magnet attachments and found that the bar variety showed greater mucosal changes. At the same time, the other group studied showed more prosthetic complications. The results for mucosal changes obtained by a similar study performed by Varshney *et al.* were in conjugation with the above study.

Systematic review and meta-analysis performed by Chaware and Thakkar compare the reports pertaining to both maxillary and mandibular arch. At the same time, the focus of the current systematic review and meta-analysis was to evaluate randomized clinical controlled trials, and crossover studies performed only in mandibular overdenture cases. The present study exclusively included those studies with a longer follow-up period. The current meta-analysis utilizes the Cochrane Collaboration Tool of Risk of bias which was not correctly represented by Chaware and Thakkar.

It was demonstrated by York that the patients’ satisfaction and quality of life were substantially improved with mandibular implant-supported overdenture than conventional dentures. The results obtained from this systematic review and meta-analysis would help injudicious selection, predictable functioning, and maximum longevity of prosthesis selected for rehabilitation of the oral cavity.

**SUMMARY OF EVIDENCE TABLE**

Summary of the included studies and the results is summarized in Table 2.

**CONCLUSION**

Out of the various treatment modalities available for rehabilitation of the edentulous mandible, the
Table 2: Summary of the included studies

| Author | Year | Follow up (years) | Type of attachment | Number of patient | Prosthodontic maintenance and complication | Retention | Peri-implant tissue condition | Patient's satisfaction |

NR: Not reported, 4IB: Four implant supported bar attachment, 2IB: Two implant supported bar attachment

mandibular implant overdentures are documented to be less invasive and more economical than fixed implant prostheses.

The best retention system requiring a minor prosthetic follow-up was the bar attachment system, provided there was good inter-ridge distance and good hygiene maintenance. Bar attachment system was the most retentive attachment for implants placed in nonparallel alignment contrary to ball attachment system, which was most favorable when implants were placed axially parallel. The telescopic attachment system showed the least mucosal changes and favorable distribution of forces. However, when the patient’s satisfaction came into the picture unsplinted a variety of attachment systems were preferred. Amongst all, the telescopic attachment system showed the most favorable satisfaction.

It was concluded from the current analysis that there was a scope for carrying out standardized studies paying specific attention to studying the same parameters for different attachment types.
