(Dated: May 5, 2014)

With use of the nonlinear Schrödinger (or Gross-Pitaevskii) equation with strong repulsive cubic nonlinearity, dynamics of multi-component Bose-Einstein condensates (BECs) with a harmonic trap in 2 dimensions is investigated beyond the Thomas-Fermi regime. In the case when each component has a single vortex, we obtain an effective nonlinear dynamics for vortex cores (particles). The particles here acquire the inertia, in marked contrast to the standard theory of point vortices widely known in the usual hydrodynamics. The effective dynamics is equivalent to that of charged particles under a strong spring force and in the presence of Lorentz force with the uniform magnetic field. The inter-particle (vortex-vortex) interaction is singularly-repulsive and short-ranged with its magnitude decreasing with increasing distance of the center of mass from the trapping center. "Chaos in the three-body problem" in the three vortices system can be seen, which is not expected in the corresponding point vortices without inertia in 2 dimensions.

I. INTRODUCTION

Recently, there has been much interest in theoretical and experimental studies on trapped atomic Bose-Einstein condensates (BECs)[1-3]. The superfluid property of atomic BECs arises from a dual aspect of waves and particles, i.e., matter waves, and is theoretically described by the macroscopic wave function. Because of the nonlinearity of the system caused by interaction between particles, the macroscopic wave function can take a form of various solitons such as bright, dark, grey, and vortex solitons, and these solitons are experimentally observed in BECs.

As for bright solitons, Martin et al.[4] theoretically predicted that the particle-like behavior of three bright solitons in a one-dimensional $^{87}$Rb BEC was non-integrable and showed its change from regular motions to chaos. Pérez-García et al.[5] applied a variational method to dynamics of bright solitons in a two-dimensional (2-d) BEC and showed that the center of mass of each soliton obeys Newtonian dynamics and Ehrenfest’s theorem is valid if the phase of BEC wave function will be suitably chosen.

As more interesting systems, we can consider solitons in multi-component BECs which consist of different kinds of atoms or same kinds of atoms having different spin and have been experimentally realized. In multi-component BECs, there are not only intra-component particle interaction but also inter-component particle interaction which is another origin of nonlinearity, so we expect novel soliton dynamics which is not seen in single-component BECs. Yamasaki et al.[6] developed a variational method to describe bright soliton dynamics in 2-d multi-components BECs, and proposed a model of conservative chaos. In 2-d and 3-d systems, however, bright soliton are unstable unless intra-component interaction oscillates between attraction and repulsion or coexisting intra-component quintic (three-body) interaction is strong enough.

On the other hand, topological vortices known as quantized vortices, i.e., topological defects of the macroscopic wave function can be stable in two dimensions. Vortices in single-component[7-9] and multi-component[10-12] BECs have been realized experimentally, giving a good candidate to study the dynamics of vortices in 2-d and 3-d BECs. Most of the theoretical studies, however, are limited to the Thomas-Fermi regime (TFR) in a single-component BEC[9, 13-15]. While dynamics of the macroscopic wave function of BEC is described by Gross-Pitaevskii equation (GPE) in Eq. (2) below, TFR suppresses the kinetic energy part in GPE in the lowest approximation and therefore the lowest-order wave function cannot have a healing length which is a hallmark of the vortex core. It is highly desirable to construct the effective theory of vortices beyond the TFR.

In this paper, we consider the vortices in 2-d multi-component BECs beyond the Thomas-Fermi regime. To
consider the effective dynamics of point-like vortices, we extract some degrees of freedom by using the variational approach, and derive an effective dynamics with finite degrees of freedom. For the case of a single-component BEC without a trap, it is well known that the effective Hamiltonian for many vortex systems has a standard form

\[ H \sim \sum_{j>i} n_in_j \ln r_{ij}, \] (1)

in the limit of infinitesimal vortex cores. Here \( n_i \) is the winding number of the \( i \)-th vortex, and \( r_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \) is the distance between cores of \( i \)-th and \( j \)-th vortices. Equation (1) shows that there is no momentum degree of freedom, and coordinates \( x_i \) and \( y_i \) are formally conjugate each other. On the other hand, in the case of multi-component BECs in a trap with each component having a single vortex, we shall see vortices acquire momentum degrees of freedom or inertia. A very preliminary idea of the present work was reported in the conference proceedings [11].

This paper is organized as follows. In Sec. III starting from the multi-component GPE, we apply the variational method with use of vortex solitons in the Padé approximation, and derive the effective Hamiltonian for vortices. Confining to the case of two and three vortices, we numerically investigate the detailed dynamics of vortices in Sec. IV There we see a chaotic behavior of the system consisting of three vortices. Section V is devoted to conclusions and discussions.

II. EFFECTIVE NONLINEAR DYNAMICS GENERATED BY THE MULTI-COMPONENT GPE

In this Section, we consider the trapped multi-component GPE with vortices and extract some degrees of freedom of vortex soliton by using a variational technique.

BEC at zero temperature is described by the GPE. We shall consider a 2-d system of trapped \( n \)-component macroscopic wave function \( \Phi_1(t, x, y), \Phi_2(t, x, y), \ldots, \Phi_n(t, x, y) \) satisfying the equations

\[ \frac{i}{\hbar} \frac{\partial}{\partial t} \Phi_i(t, x, y) = \left[ -\nabla^2 + V(x, y) + g_{ii}\Phi_i(t, x, y) \right] \Phi_i(t, x, y), \]

for \( i, j = 1, \ldots, n \). Here the normalization condition for each component of wave functions is defined by \( \int |\Phi_i(t, x, y)|^2 dx dy = 1 \) after a proper rescaling of \( \Phi_i \) by the particle number \( N \) common to all components. The effect of trapping is expressed by \( V(x, y) = (x^2 + y^2) \).

Equation (2) is expressed with use of scaled variables: using the confining length \( l = \sqrt{\frac{\hbar^2}{m}} \) and oscillation period \( \tau = \omega^{-1} \), space coordinates are scaled by \( l \), time by \( 2\pi \), wave function by \( \frac{1}{\sqrt{\tau}} \), and nonlinearity by \( \frac{\hbar^2}{2m} \). The nonlinearity coefficients, \( g_{ij} \equiv 8\pi N a_{ij}/l \) with \( a_{ij} \) the scattering length for binary collisions, are assumed to be positive and much larger than unity. \( g_{ii} \) and \( g_{ij} \) with \( i \neq j \) stand for intra-component and inter-component interactions, respectively. We shall choose \( g_{ii} = g_1(\gg 1) \) for all \( i \) and \( g_{ij} = g_2(\gg 1) \) for \( i \neq j \).

In the absence of the inter-component interaction, each component has stationary states of a vortex. So, we consider the case in which each component has one vortex and vortices interact with each other through the inter-component interaction. Our goal is to derive from (2) the evolution equation for the collective coordinates of trial vortex functions (TVFs). The collective coordinates for a vortex are phase variables besides the coordinates of a vortex core. We shall use TVF beyond the Thomas-Fermi regime, by incorporating the effect of a kinetic energy in GPE in Eq.(2): As for the amplitude of TVF, we choose a vortex function based on the Padé approximation [20, 21] which is regularized due to a trap. As for its phase, we Taylor-expand the phase with respect to space coordinates around the vortex core. Then TVF with winding number \( n_i = \pm 1 \) is given by

\[
\Phi_i(t, x, y) \equiv f_i(t, x, y) \exp[i\phi_i(t, x, y)] = N \exp \left[ -\frac{x^2 + y^2}{2\Delta} \right] \sqrt{\frac{(x-x_i)^2 + (y-y_i)^2}{2\epsilon_r^2 + (x-x_i)^2 + (y-y_i)^2}} \times \exp \left[ i \left( n_i \tan^{-1} \left( \frac{y-y_i}{x-x_i} \right) + \alpha_i(x-x_i) + \beta_i(y-y_i) \right) \right]
\] (3)

with the normalization factor \( N = \sqrt{\Gamma(\Delta-2\pi^{1/2} \xi^2 \Gamma(0, \Delta^{1/2}))} \). Here \( \Gamma(0, z) \equiv \int_z^\infty t^{-1} e^{-t} dt \) is the incomplete gamma function of the second kind, whose expansion with respect to \( z \) is given in Eq. A10 in Appendix A.

The collective coordinates are locations of the core \((x_i, y_i)\) and the first-order coefficients \((\alpha_i, \beta_i)\) of Taylor-
In fact, Eq. (2) is obtained from Lagrange equation:

\[ E = \int dx dy (\nabla \Phi_i)^2 + V(x, y) |\Phi_i|^2 + g_2 |\Phi_i|^4 \]

for the individual static component in Eq. (3) centered at the origin, leads to \( \Delta \approx \sqrt{2 - (\gamma + 1) n_2^2 + \frac{2 \gamma}{\xi^2}} \) and \( \xi \approx \frac{\sqrt{2} \pi y_1}{2 + \gamma} \), respectively, where \( \gamma(= 0.57721) \) is Euler constant. We shall use these values for \( \Delta \) and \( \xi \) in this paper.

The form in Eq. (3), which is a product of the vortex solution in the absence of a harmonic trap and Gaussian factor due to the trap, gives a suitable TVF for a vortex under the strong nonlinearity. A different form with use of eigenstates (with non-zero angular momenta) under the 2-d harmonic trap \[22, 23\] has no small healing length, results in the inter-vortices force growing with inter-vortices distance, etc, and cannot be suitable as TVF under the strong nonlinearity.

First of all we note: GPE in Eq. (2) can be derived from the variational principle that minimizes the action obtained from Lagrangian density \( L \) for field variables,

\[ -L = \sum_i \left[ \frac{i}{2} (\Phi_i \dot{\Phi}_i - \Phi_i^* \dot{\Phi}_i^*) + |\nabla \Phi_i|^2 + (x^2 + y^2)|\Phi_i|^2 + \frac{g_i}{2} |\Phi_i|^4 \right] + \sum_{j>i} g_{ij} |\Phi_i|^2 |\Phi_j|^2. \]

(4)

In fact, Eq. (3) is obtained from Lagrange equation:

\[ \frac{\partial}{\partial t} \frac{\partial L}{\partial \dot{\Phi}_i} - \frac{\partial L}{\partial \Phi_i} + \nabla \frac{\partial L}{\partial \nabla \Phi_i} = 0. \]

(5)

We now insert TVF in Eq. (3) into Eq. (4). Noting \((x_i, y_i)\) and \((\alpha_i, \beta_i)\) as time-dependent variables, Eq. (4) becomes

\[ -L = \sum_i \left[ x_i \frac{\partial \phi_i}{\partial x_i} + y_i \frac{\partial \phi_i}{\partial y_i} + \dot{\alpha}_i \frac{\partial \phi_i}{\partial \alpha_i} + \dot{\beta}_i \frac{\partial \phi_i}{\partial \beta_i} \right] f_i^2 + \left( \frac{\partial f_i}{\partial x} \right)^2 + \left( \frac{\partial f_i}{\partial y} \right)^2 + \left( \frac{\partial \phi_i}{\partial x} \right)^2 + \left( \frac{\partial \phi_i}{\partial y} \right)^2 \right] f_i^2 + \frac{g_i}{2} f_i^4 + (x^2 + y^2) f_i^2 + g_2 \sum_{j>i} f_i^2 f_j^2. \]

(6)

By integrating \( L \) over space coordinates \((x, y)\), we obtain the effective Lagrangian \( L \) for the collective coordinates:

\[ L = \int \int dx dy L. \]

(7)

In the limit of \( \xi^2/\Delta \ll 1 \), \( L \) is expressed by

\[ -L = \left( \frac{N}{N_0} \right)^2 \sum_i \left[ -\frac{n_i}{\Delta} (x_i y_i - y_i x_i) e^{-i \frac{\pi}{4}} \left( d_1 + \frac{d_2 f_i^2}{\Delta} \right) + (\alpha_i^2 + \beta_i^2 - (\alpha x_i + \beta y_i)) \right] d_i - (\alpha_i x_i + \beta_i y_i) \left( 1 - \frac{2c^2}{\Delta} \left( 1 - \frac{l_i^2}{2\Delta} \right) \right) + \frac{1}{\Delta} e^{-i \frac{\pi}{4}} \left( 2n_i d_i + d_i + 2n_i^2 l_i^2 d_i + d_i l_i^2 \right) + 2n_i (y_i \alpha_i - x_i \beta_i) e^{-i \frac{\pi}{4}} \left( d_1 + \frac{d_2 f_i^2}{\Delta} \right) + e^{-i \frac{\pi}{4}} \left( d_8 + l_i^2 d_i \right) + \left( \frac{N}{N_0} \right)^2 \frac{g_1}{\pi \Delta} \left( \frac{1}{4} + d_7 e^{-i \frac{\pi}{4}} \right) \right] + \sum_{j>i} U(r_{ij}, l_i^2). \]

(8)

Here, \( l_i = \sqrt{x_i^2 + y_i^2} \) and \( N_0 = \frac{\sqrt{2} \pi y_1}{2 + \gamma} \). Expressions (: Taylor-expansions with respect to \( \xi^2/\Delta \)) for coefficients \( d_1 \sim d_9 \) are listed in Table 1 and the derivation of typical coefficients is described in Appendix A. The expression for the inter-vortices interaction \( U(r_{ij}, l_i^2) \), which is a function of inter-vortices distance \( r_{ij} = \sqrt{x_i^2 + y_i^2} \) and distance of the center of masses from the origin \( l_i^2 = \sqrt{(x_i^2) + (y_i^2)^2} \), will be given in Appendix B.

Lagrange equations of motion for the phase variables \( \alpha_i \) and \( \beta_i \),

\[ \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{\alpha}_i} \right) - \frac{\partial L}{\partial \alpha_i} = 0 \]

\[ \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{\beta}_i} \right) - \frac{\partial L}{\partial \beta_i} = 0 \]

(9)

lead to

\[ \alpha_i \approx B_1 x_i - n_1 B_2 y_i \]

\[ \beta_i \approx B_1 y_i + n_1 B_2 x_i. \]

(10)

Equation (11) shows that \( (\alpha_i, \beta_i) \) correspond to generalized momentum conjugate to \((x_i, y_i)\) under the vector potential. Then the equation of motion for \((x_i, y_i)\),

\[ \frac{d}{dt} \left( \frac{\partial L}{\partial x_i} \right) - \frac{\partial L}{\partial x_i} = 0 \]

\[ \frac{d}{dt} \left( \frac{\partial L}{\partial y_i} \right) - \frac{\partial L}{\partial y_i} = 0, \]

(12)
\[ \ddot{x}_i \simeq n_i B_3 y_i - B_4 x_i - B_5 \sum_{j \neq i} \frac{\partial U(x_i, y_i)}{\partial x_i} \]
\[ \ddot{y}_i \simeq -n_i B_3 \dot{x}_i - B_4 y_i - B_5 \sum_{j \neq i} \frac{\partial U(x_i, y_i)}{\partial y_i}. \]  

(13)

**Table 1.** Expressions for coefficients in Eq. (8) (: Taylor-expansions with respect to \( \xi^2 / \Delta \)).

| Coefficients | Expressions |
|--------------|-------------|
| \( d_1 \)   | \( 1 + \frac{2 \xi^2}{\Delta} + \frac{\xi^2}{\Delta} \ln \frac{\xi^2}{\Delta} \) |
| \( d_2 \)   | \( \frac{1}{\Delta} \) |
| \( d_4 \)   | \( - \frac{d_1}{\Delta} - \frac{2 \xi^2}{\Delta} + \frac{\xi^2}{\Delta} \ln \frac{\xi^2}{\Delta} \) |
| \( d_5 \)   | \( \frac{\Delta^2}{d_1 - 1 + \frac{2 \xi^2}{\Delta} } \) |
| \( d_6 \)   | \( 1 + \frac{\xi^2}{\Delta} + \frac{\Delta^2}{\Delta \ln \frac{\xi^2}{\Delta}} \) |
| \( d_7 \)   | \( \frac{\Delta^2}{\xi^2 + \frac{\Delta^2}{\ln \frac{\xi^2}{\Delta}}} \) |
| \( d_8 \)   | \( \Delta - 2 \xi^2 \) |

Coefficients \( B_1 \sim B_5 \) are given by

\[
B_1 = \frac{d_1 - 1 + \frac{2 \xi^2}{\Delta} }{2d_1} \sim \frac{(\gamma + 1) \xi^2}{\Delta} \\
B_2 = \frac{1}{\Delta} \\
B_3 = - \frac{4d_1 d_2}{\Delta(d_1 - 1 + \frac{2 \xi^2}{\Delta})^2} \sim - \frac{\Delta}{(\gamma + 1)^2 \xi^4} \\
B_4 = \frac{\Delta^2}{(d_1 - 1 + \frac{2 \xi^2}{\Delta})^2} \sim \frac{\Delta^2}{(\gamma + 1)^2 \xi^4} \\
B_5 = \left( \frac{N}{N_0} \right)^2 \frac{2d_1}{(d_1 - 1 + \frac{2 \xi^2}{\Delta})^2} \sim \frac{\Delta^2}{2(\gamma + 1)^2 \xi^4}. \]  

(14)

Equations (10) and (13) are valid aside from a multiplicative global factor \((1 + O(\frac{\xi^2}{\Delta}))\). The smallness of \( \frac{\xi^2}{\Delta} \) will be justified \textit{a posteriori}. Equation (13) shows that dynamics of coordinates \((x_i, y_i)\) is very similar to charged particles with charges \( n_i = \pm 1 \) under a strong spring force with a force constant \( B_4 = O(\xi \Delta) \) and in the presence of Lorentz force with the magnetic field \( \mathbf{B} = (0, 0, B_3) \). One should note that the spring force here has nothing to do with that of the original harmonic potential \( V(x, y) \) in Eq. (2). The Hamiltonian corresponding to Eqs. (13) can be given by

\[
H = \sum_i \left[ \frac{1}{2m} [\mathbf{p}_i - n_i \mathbf{A}_i]^2 + W_i + \sum_{j > i} \tilde{U}(r_{ij}, t^i_G) \right]. \]  

(15)

with use of the momentum \( \mathbf{p}_i = m \dot{x}_i + n_i \mathbf{A}_i \), unit mass \( m = 1 \), the vector potential \( \mathbf{A}_i = B_3 (y_i, x_i) \), and the scalar potential \( W_i = \frac{1}{2} B_4 (x_i^2 + y_i^2) \).

All values \( B_1 \sim B_5 \) depend on the strength of interaction \( g_1 \) which is tunable by Feshbach resonance. In the effective particle dynamics described by Eqs. (12) and (15), the spring constant \( B_4 \) is large enough to guarantee particles with unit mass to be confined in the neighborhood of the origin, i.e., the trapping center. This finding justifies \( \frac{\xi^2}{\Delta} \ll 1 \) and will also be utilized to obtain the inter-vortices interaction in Appendix B.

The scaled inter-vortices interaction \( \tilde{U}(r_{ij}, t^i_G) \) is given with use of Eq. (110) as

\[
\tilde{U}(r_{ij}, t^i_G) = B_3 U_4(r_{ij}, t^i_G) 
\approx \frac{G}{r_{ij}^2 \exp \left( - \frac{r_{ij}^2 + 4(t^i_G)^2}{2 \Delta} \right)} \]  

(16)

with the coupling constant

\[
G = \frac{4g_2}{(\gamma + 1)^2 \pi^{1/2}}. \]  

(17)

Therefore the inter-vortices interaction is singularly-repulsive and short-ranged with respect to \( r_{ij} \) with its magnitude decreasing with increasing \( t^i_G \).

Compared to Eq. (11), it is clear that the system has momentum degrees of freedom, and vortices have a behavior of particle with inertia rather than that of vortex
of hydrodynamics. This is one of the main assertions of the present paper. The inertia of vortex appears already in the single-component BEC with a trap.

In closing this Section we should comment: we also attempted to apply the collective coordinate method using a Laguerre-type trial function which is a good candidate for TVF in the case of a weak nonlinearity. However, such TVF in the case of a strong nonlinearity proved to result in: 1) a time-dependent mass for each vortex and 2) the inter-vortex interaction growing with increasing the inter-vortex distance. Hence this TVF was not suitable to describe a dynamics of vortices in BECs with a strong nonlinearity. On the other hand, the effective vortex dynamics in the Thomas-Fermi regime, which suppresses the kinetic energy in constructing TVF, leads to neither non-zero inertia nor Lorentz force.

III. DYNAMICS OF TWO AND THREE VORTICES WITH INERTIA

We shall now focus on the system of two vortices with equal winding numbers, and see how the trajectory generated by effective particle dynamics in Eq. (13) and (15) well mimics the orbit of the singular points of wave vortices calculated by using GPE in Eq. (2). We shall then move to the system of three vortices with equal winding numbers, and find that chaos appears even in the three vortex system. This feature is different from that of point vortices system in a single component BEC in which chaos can appear in the case of more than three vortices.

A. Dynamics of two vortices

For two vortices with the same winding numbers \( n_1 = n_2 = 1 \), Hamiltonian (15) can be rewritten as

\[
H = \frac{1}{2}(p_{x,T}^2 + p_{y,T}^2 + p_{x,R}^2 + p_{y,R}^2) - \frac{B_3}{4}(p_{x,T}y_T - p_{y,T}x_T + p_{x,R}y_R - p_{y,R}x_R) + \left( \frac{B_3^2}{8} + \frac{B_1}{2} \right)(x_T^2 + y_T^2 + x_R^2 + y_R^2) + \frac{G}{2(x_R^2 + y_R^2)} \exp \left( \frac{-x_R^2 + y_R^2 + x_T^2 + y_T^2}{\Delta} \right),
\]

where \((x_T, y_T)\) and \((x_R, y_R)\) play the role of the center-of-mass and relative coordinates, respectively and

\[
(p_{x,T}, p_{y,T}) \text{ and } (p_{x,R}, p_{y,R})\] are their canonical-conjugate variables. To be explicit,

\[
(x_T, y_T) = \frac{1}{\sqrt{2}}(x_1 + x_2, y_1 + y_2) \]

\[
(x_R, y_R) = \frac{1}{\sqrt{2}}(x_1 - x_2, y_1 - y_2) \]

\[
(p_{x,T}, p_{y,T}) = \frac{1}{\sqrt{2}}(p_{x,1} + p_{x,2}, p_{y,1} + p_{y,2}) \]

\[
(p_{x,R}, p_{y,R}) = \frac{1}{\sqrt{2}}(p_{x,1} - p_{x,2}, p_{y,1} - p_{y,2}).
\]

Hamiltonian (15) cannot be reduced to two independent two degree-of-freedom subsystems (center-of-mass system and relative-coordinates system) because the inter-vortex interaction depends not only on \( r_{ij} \) but...
also on \( \Omega_l \). However, we see mostly KAM tori in this system. As shown in Fig. 1 we find that the trajectory of \((x_R, y_R)\) generated by effective two-particle dynamics well mimics the corresponding orbit obtained by a pair of singular points calculated by using GPE in Eq. (2). This fact justifies the validity of our trial function in Eq. (3) and the resultant equation of motion for collective coordinates in Eqs. (3) and (15).

**B. Dynamics of three vortices**

Encouraged by the effectiveness of the collective coordinate method in the case of two vortices, we proceed to the dynamics of three vortices with the identical winding numbers \( n_1 = n_2 = n_3 = 1 \), whose Hamiltonian becomes

\[
H = \frac{1}{2} \left( p_{xC}^2 + p_{yC}^2 + p_{xT}^2 + p_{yT}^2 + p_{xR}^2 + p_{yR}^2 \right) - \frac{B_3}{2} \left( x_C y_R - x_T y_T - x_R y_T \right) - \frac{B_1}{2} \left( x_C x_T - y_R y_T - y_R x_T \right) + \frac{B_2^2}{8} + \frac{B_4}{2} \left( x_C^2 + x_T^2 + x_R^2 + y_C^2 + y_T^2 + y_R^2 \right) + \sum_{(i,j)=(1,2), (2,3), (3,1)} \frac{G}{(x_i - x_j)^2 + (y_i - y_j)^2} \times \exp \left( -\frac{x_i^2 + y_i^2 + x_j^2 + y_j^2}{\Delta} \right),
\]

where Jacobi coordinates \((x_T, y_T, etc)\) are defined by

\[
\begin{align*}
(x_T, y_T) &= \frac{1}{\sqrt{3}}(x_1 + x_2 + x_3, y_1 + y_2 + y_3) \\
(x_C, y_C) &= \frac{1}{\sqrt{2}}(x_1 - x_2, x_1 + x_2 + x_3, y_1 + y_2 + y_3) \\
(x_R, y_R) &= \frac{1}{\sqrt{6}}(x_1 + x_3 - 2x_2, y_1 + y_3 - 2y_2) \\
(p_{xR}, p_{yR}) &= \frac{1}{\sqrt{6}}(p_{x1} + p_{x3} - 2p_{x2}, p_{y1} + p_{y3} - 2p_{y2}) \\
(p_{xT}, p_{yT}) &= \frac{1}{\sqrt{3}}(p_{x1} + p_{x2} + p_{x3}, y_1 + y_2 + y_3) \\
(p_{xC}, p_{yC}) &= \frac{1}{\sqrt{2}}(p_{x2} - p_{x1}, p_{x2} - p_{x1}),
\end{align*}
\]

which conserve the canonical structure \(\{x_T, p_{xT}\} = \frac{1}{4} \sum_{j=1}^{3} \{x_j, p_{xj}\} = 1\), etc.). Here \((x_T, y_T), (x_C, y_C)\), and \((x_R, y_R)\) represent the center of mass of all three components, the relative displacement, and the bisector of the vertex \((x_2, y_2)\), respectively. In marked contrast to the massless three vortex system in 2 dimensions which is integrable, all 6 degrees of freedom are coupled and the number of independent constants of motion is 2 (energy and \(z\)-component of angular momentum). Then Poincaré-Bendixon’s theorem guarantees the nonintegrability and chaos of the three inertial vortex system 30.

We can construct from (20) the canonical equations of motion for \(x_T, y_T, x_C, y_C, x_R, y_R\) and their canonical-conjugate variables, which is solved numerically. Poincaré cross section and power spectra for the kinetic energy \(E_k(t)\) in Fig. 2 give a clear evidence of high-dimensional chaos. Because of the short-range nature of the interaction, we see the emergence of chaos in low-lying energy regions where vortices often meet each other.

![FIG. 2: Three vortices dynamics with identical winding numbers \((n_1 = n_2 = n_3 = 1)\). \(g_1 = g_2 = 100\). Initial values: \(x_R(0) = x_C(0) = x_T(0) = 1, y_R(0) = -1, y_C(0) = y_T(0) = 1; p_{xR}(0) = p_{xC}(0) = p_{xT}(0) = p_{yR}(0) = p_{yC}(0) = p_{yT}(0) = 1\). IV. CONCLUSION

We explored vortex dynamics in the 2-dimensional multi-component BEC in the harmonic trap in the case that each component has a single vortex. The investigation beyond the Thomas-Fermi regime is made on the nonlinear Schrödinger equation with strong repulsive cubic nonlinearity. With use of a trial vortex function based on the Padé approximation which is regularized due to a trap, we applied a collective coordinates method, obtaining an effective nonlinear dynamics for vortex cores (particles), which is equivalent to charged particles with inertia under a strong spring force and in the presence of Lorentz force with the uniform magnetic field. The inter-particle interaction is singularly-repulsive and short-ranged with its magnitude decreasing with increasing distance of the center of mass from the trapping center. The most important finding is the nonzero inertia of vortices, which is not present in the conventional theory of point vortices widely used in the usual hydrodynamics [25–29]. The system of three vortices with inertia can be chaotic, in contrast to the corresponding case of point vortices without inertia.

Acknowledgments. One of the authors (K. N.) is grateful to F. Abdullaev, B. Baizakov, S. Dmitriev and M. Tsubota for useful comments in various important stages of this work.

Appendix A: Calculation of typical integrals

We shall calculate some integrals used in this paper.

1. Integral $A \equiv \int \int dxdy f_i^2 \left( \dot{x}_i \frac{\partial \phi_i}{\partial x} + \dot{y}_i \frac{\partial \phi_i}{\partial y} \right)$

Substituting Eq. (3) into the above integrand, we find

\[
A = \frac{1}{\pi \Delta} \left( \frac{N}{N_0} \right)^2 \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dxdy e^{-\frac{(x-x_i)^2}{2\xi^2} - \frac{(y-y_i)^2}{2\rho^2}}
\]

\[
\times \left[ \frac{N}{2\xi^2 + (x-x_i)^2 + (y-y_i)^2} \right. \\
\left. - \left( \alpha_i \dot{x}_i + \beta_i \dot{y}_i \right) \right]
\]

\[
\times \frac{(x-x_i)^2 + (y-y_i)^2}{2\xi^2 + (x-x_i)^2 + (y-y_i)^2},
\]

(A1)

where $N_0 = \frac{1}{\sqrt{2\pi \Delta}}$ and $N$ is the normalization constant defined below Eq. (3). Equation (A1) is a sum of $n_i$-dependent term ($A_1$) and $(\alpha_i, \beta_i)$-dependent term ($A_2$).

Below we shall concentrate on $A_1$ because $A_2$ is easily calculable. Using polar coordinates as

\[
x - x_i = \rho \cos \theta \quad x_i = l_i \cos \phi_i \\
y - y_i = \rho \sin \theta \quad y_i = l_i \sin \phi_i
\]

\[dxdy = \rho d\rho d\theta\]

we rewrite the integral $A_1$ as

\[
A_1 = \frac{n_i}{\pi \Delta} \left( \frac{N}{N_0} \right)^2 \int_0^\infty \int_0^\infty d\rho e^{-\frac{\rho^2}{2\xi^2}} e^{-\frac{\rho^2}{2\rho^2}}
\]

\[
\times \int_0^{2\pi} d\theta (\dot{x}_i \sin \theta - \dot{y}_i \cos \theta) e^{-\frac{\rho^2}{2\rho^2} \cos (\theta - \phi_i)}.
\]

(A2)

The $\theta$-integration gives

\[
\int_0^{2\pi} d\theta (\dot{x}_i \sin \theta - \dot{y}_i \cos \theta) e^{-\frac{\rho^2}{2\rho^2} \cos (\theta - \phi_i)}
\]

\[
= \int_0^{2\pi} d\theta \left( \dot{x} \cos \phi_i + \dot{y} \sin \phi_i \right) \sin \theta
\]

\[
+ (\dot{x} \sin \phi_i - \dot{y} \cos \phi_i) \cos \theta e^{-\frac{\rho^2}{2\rho^2} \cos \theta}
\]

\[
= -\pi (\dot{x} y_i - \dot{y} x_i) \left( \frac{2\rho}{\Delta} + \frac{\rho^3 l_i^2}{\Delta^3} \right).
\]

(A3)

Here we took $\dot{\theta} = \theta - \phi_i$ and used the formulas like

\[
\int_0^{2\pi} d\theta \cos \theta e^{-z \cos \theta} = -2\pi I_1(z),
\]

(A5)

where $I_1(z)$ is the modified Bessel function, which is expanded as

\[
I_1(z) = \frac{z}{2} + \frac{z^3}{16} + O(z^5).
\]

(A6)

As for $\rho$-integration, we use identities like

\[
\frac{\rho^3}{2\xi^2 + \rho^2} = \rho - \frac{2\xi^2 \rho}{2\xi^2 + \rho^2}
\]

and then apply the formulas

\[
\int_0^{\infty} d\rho \rho^m e^{-\frac{\rho^2}{2\xi^2}} = \frac{1}{2} \Delta^{\frac{m+1}{2}} \Gamma \left( \frac{n+1}{2} \right)
\]

(A7)

and

\[
\int_0^{\infty} d\rho e^{-\frac{\rho^2}{2\xi^2}} \frac{\rho}{2\xi^2 + \rho^2} = \frac{1}{2} e^{rac{2\xi^2}{\Delta}} \Gamma \left( 0, \frac{2\xi^2}{\Delta} \right)
\]

\[
= \frac{1}{2} e^{rac{2\xi^2}{\Delta}} \left( -\gamma - \ln \frac{2\xi^2}{\Delta} + 2\xi^2 - \left( \frac{2\xi^2}{\Delta} \right)^2 \right).
\]

(A9)
\[
\Gamma(0, z) \equiv \int_0^\infty t^{-1} e^{-tdt} \text{above is the incomplete gamma function of the second kind and can be expanded as}
\]
\[
\Gamma(0, z) = -\gamma - \ln z + z - \frac{z^2}{4} + \frac{z^3}{18} + O(z^4). \quad (A10)
\]

The final result is
\[
A_1 = -\left(\frac{N}{N_0}\right)^2 \frac{n_1}{\Delta} (x_i y_i - y_i x_i) e^{-\frac{i^2}{\Delta}} \left( d_1 + \frac{d_2 i^2}{\Delta} \right), \quad (A11)
\]
where \(d_1\) and \(d_2\) are listed in Table 1. Equation (A11), combined with
\[
A_2 = -\left(\frac{N}{N_0}\right)^2 (\alpha_i \dot{x}_i + \beta_i \dot{y}_i) d_1, \quad (A12)
\]
gives rise to the calculated result for \(A\) in Eq. (A1).

2. Integral \(B \equiv \frac{2i}{\pi} \int \int f_i^4 dxdy\)

\[
B = \frac{g_1}{2\pi^2 \Delta^2} \left(\frac{N}{N_0}\right)^4 \int_0^\infty d\rho e^{-\frac{2(i^2 + \rho^2)}{\Delta}} \int_0^\infty \int d\rho' e^{-\frac{2(i^2 + \rho'^2)}{\Delta}} \times \frac{\rho^2}{2\xi^2 + \rho^2} \frac{2\pi}{4 \rho' \rho e^{-\frac{4\pi}{\Delta} \cos(\theta - \phi)}}, \quad (A13)
\]
Using polar coordinates in (A12), we rewrite the integral as
\[
B = \frac{g_1}{2\pi^2 \Delta^2} \left(\frac{N}{N_0}\right)^4 \int d\rho e^{-\frac{2(i^2 + \rho^2)}{\Delta}} \int_0^\infty \int d\rho' e^{-\frac{2(i^2 + \rho'^2)}{\Delta}} \times \frac{\rho^2}{2\xi^2 + \rho^2} \frac{2\pi}{4 \rho' \rho e^{-\frac{4\pi}{\Delta} \cos(\theta - \phi)}}, \quad (A14)
\]
First, we carry out the \(\theta\)-integration. Note that
\[
\int_0^{2\pi} d\theta e^{-z \cos \theta} = 2\pi I_0(z) \quad (A15)
\]
where \(I_0(z)\) is the modified Bessel function, which is expanded as
\[
I_0(z) = 1 + \frac{z^2}{4} + \frac{z^4}{64} + O(z^6). \quad (A16)
\]
Concerning the \(\rho\)-integration, we first employ the decomposition
\[
\frac{\rho^4}{(2\xi^2 + \rho^2)^2} = 1 - \frac{4\xi^2}{2\xi^2 + \rho^2} + \frac{4\xi^4}{(2\xi^2 + \rho^2)^2}. \quad (A17)
\]
and then apply the formulas like
\[
\int_0^\infty d\rho e^{-\frac{2i^2}{\Delta}} I_0 \left( \frac{4\rho i}{\Delta} \right) = \frac{\Delta}{4} e^{\frac{2i^2}{\Delta}}. \quad (A18)
\]
The final result is
\[
B = \left(\frac{N}{N_0}\right)^4 g_1 \frac{1}{\pi \Delta} \left[ 1 + d_7 e^{-\frac{2i^2}{\Delta}} \right], \quad (A19)
\]
where \(d_7\) is given in Table 1.

Appendix B: Calculation of inter-vortices interaction \(U\)

This interaction is due to the integral
\[
U \equiv g_2 \int \int f_i^4 f_j^4 dxdy \quad (B1)
\]
With use of a prescription \(U \equiv \frac{g_2}{\pi^2 \Delta^2} \left(\frac{N}{N_0}\right)^4 \hat{U}\), the integral becomes:
\[
\hat{U} = \int_0^\infty d\rho e^{-\frac{2(i^2 + \rho^2)}{\Delta}} \times \frac{1 - 2\xi^2}{\left(2\xi^2 + (x - x_i)^2 + (y - y_i)^2 \right)} \left( i \rightarrow j \right) \quad (B2)
\]
\[
\hat{U}_0 + \hat{U}_2 + \hat{U}_4.
\]
\(\hat{U}_0, \hat{U}_2\) and \(\hat{U}_4\) corresponds to the contributions from \(O(\xi^6), O(\xi^2)\) and \(O(\xi^4)\), respectively. Among them, \(\hat{U}_4\) is responsible to the vortex-vortex interaction, which we shall calculate below.

Let’s define the center-of-mass and relative coordinates by
\[
x_{ij} = \frac{x_j + x_i}{2}, \quad y_{ij} = \frac{y_j + y_i}{2} \quad (B3)
\]
FIG. 3: New integration variables, center-of-mass and relative coordinates.

and

\[ x_i - x_j = r_{ij} \cos \phi_{ij}; \quad y_i - y_j = r_{ij} \sin \phi_{ij}, \quad (B4) \]

respectively, and transform the integration variables to new ones as (see Fig. 3)

\[ x - x_G^i = \rho \cos \theta, \quad x_G^i = x_G^i + l_i^j \cos \phi_{ij} \]
\[ y - y_G^i = \rho \sin \theta, \quad y_G^i = y_G^i + l_i^j \sin \phi_{ij} \]
\[ \int d\theta d\rho d\phi \]

Then \( \hat{U}_4 \) in Eq. (B2) becomes

\[ \hat{U}_4 = \int_0^{2\pi} \int_0^\infty \rho e^{2\pi \left( (1/2)\rho^2 + 2\rho r_{ij}^2 \cos(\theta' + \phi_{ij} - \phi_G^i) \right)} \]
\[ \times \left[ \frac{4\pi^4}{(2\rho^2 + \rho^2 r_{ij}^2)^2 - \rho^2 r_{ij}^2 \cos^2(\theta')} \right], \quad (B6) \]

where we moved to a new angle variable \( \theta' = \theta - \phi_{ij} \).

Using the expansion

\[ e^{-x \cos(\theta' + \alpha)} = \sum_{n=-\infty}^{\infty} (-1)^n I_n(x) \sin^n(\theta') \quad (B7) \]

in Eq. (B6) and keeping the \( n = 0 \) term, the integration over the angle variable leads to:

\[ \int_0^{2\pi} d\theta' e^{2\pi \left( (1/2)\rho^2 + 2\rho r_{ij}^2 \cos(\theta' + \phi_{ij} - \phi_G^i) \right)} \]
\[ \approx \frac{8\pi^4}{2\rho^2 + \rho^2 r_{ij}^2} \]
\[ \times \frac{1}{\sqrt{\left( 2\rho^2 + \rho^2 (\phi_{ij} - \phi_G^i)^2 \right) \left( 2\rho^2 + \rho^2 (\phi_{ij} + \phi_G^i)^2 \right)}}, \quad (B8) \]

where we used the formula \( \int_0^{2\pi} \frac{1}{e^a + e^b} = \frac{2\pi}{\sqrt{(a+b)(a-b)}} \).

We shall proceed to \( \rho \) integration. Here we should note: In the case \( \xi \ll 1 \), the Lorentzian-like function on r.h.s. of Eq. (B5) is sharply peaked around \( \rho \approx \frac{l_{ij}^2}{\xi} \) and is well approximated for \( \rho > 0 \) by Gaussian, \( \frac{\sqrt{\pi} \rho^3}{l_{ij}^2} \exp \left( -\frac{(\rho - l_{ij}^2)}{2\xi^2} \right) \). Therefore, the \( \rho \) integration leads to:

\[ \hat{U}_4 = \frac{8\sqrt{2\pi} \xi^3}{l_{ij}^3} e^{-\frac{2(l_{ij}^2)}{\xi^2}} \]
\[ \times \left[ \int_0^\infty \rho e^{2\pi \left( (1/2)\rho^2 + 2\rho r_{ij}^2 \cos(\theta' + \phi_{ij} - \phi_G^i) \right)} \int_0^\infty \exp \left( -\frac{(\rho - r_{ij})^2}{4\xi^2} \right) d\rho \right] \]
\[ = \frac{8\pi^{3/2} \xi^4}{(1 + \xi^2/(\Delta))(1 + 8\xi^2/(\Delta)^2)^{1/2} r_{ij}^3} \int_0^\infty \frac{1}{\Delta(1 + 8\xi^2/\Delta)} \]
\[ \times \exp \left( -\frac{l_{ij}^2}{\Delta} \right) \exp \left( -\frac{r_{ij}^2}{2\Delta(1 + 8\xi^2/\Delta)} \right), \quad (B9) \]

where the integration was carried out by the saddle-point approximation which is justified in the case \( \xi \ll 1 \). Since each vortex dynamics occurs in the range \( 2\xi/(\Delta r_{ij}) \ll 1 \) because of the notation above Eq. (B6) in Sec. III, we may approximate \( \int_0^\infty \frac{1}{\Delta(1 + 8\xi^2/\Delta)} \sim 1 \) and neglect the contributions from \( I_n(x) \) with \( n = 1, 2, \ldots \) in the region \( x \ll 1 \). Then we reach

\[ U_4 \equiv U_4(r_{ij}, t_G^i) \equiv \frac{g_2}{\pi^2 \Delta^2} \left( \frac{N}{N_0} \right)^4 \hat{U}_4 \]
\[ \approx 8g_2 \xi^4 \frac{1}{\pi^2 \Delta^2} \exp \left( -\frac{r_{ij}^2 + 4l_{ij}^2/\Delta}{2\Delta} \right) \quad (B10) \]

with use of \( \left( \frac{N}{N_0} \right)^4 \approx 1 \). At first the magnitude of the inter-vortices interaction looks very small (i.e., \( O(\xi^4) \)), but, after scaling to make unity the inertial mass of each vortex, it becomes \( O(g_2) \) (see Eq. (17)). It is interesting that the inter-vortices interaction energy in a multi-component BEC with no trap estimated in a different approximation (i.e., under the Abrikosov ansatz) is also proportional to \( \frac{1}{\Delta} \) in the asymptotic region \([31]\).

Finally we note the remaining contributions, \( \hat{U}_0 + \hat{U}_2 \), in Eq. (B2). Their integration is quite simple and gives rise to

\[ U_0 + U_2 \equiv \frac{g_2}{\pi^2 \Delta^2} \left( \frac{N}{N_0} \right)^4 (\hat{U}_0 + \hat{U}_2) \]
\[ \approx \frac{g_2}{\pi^2 \Delta^2} \left( \frac{N}{N_0} \right)^4 \left[ \frac{1}{2} + 2\frac{\xi^2}{\Delta^2} \ln \left( \frac{2\xi^2}{\Delta} \right) (e^{-\frac{1}{2\gamma}} + e^{-\frac{1}{2\gamma}}) \right]. \quad (B11) \]
In the final expression, the first term is constant, giving no contribution to the dynamics in Eq. (13), and the second one is a sum of single-particle contributions of $O(\frac{g^2}{\Delta})$ which renormalizes the 7-th line in Eq.(8), giving no substantial contribution to Eq.(13).

[30] In the usual theory of hydrodynamics, interacting point vortices in 2 dimensions have 3 independent constants of motion, i.e., total energy, $x$-(or $y$-) component of momentum and $z$-component of angular momentum. Therefore the number of vortices must be larger than 3, to make the system non-integrable and chaotic.
