existing models noted: a shift of attention to a specialist, but not to a client; borrowing static and absolutistic ideas about cultures, without consideration of cultures development and interaction.

Conclusions: There is a trend in contemporary global world for broad research and development of cultural competence that improve professional qualities of healthcare professionals and provide psychological assistance to representatives of different ethnic and culture groups, confessions and minorities. The reported study was funded by the Russian Foundation for Basic Research, project number 17-29-02506.

Introduction: Previously reported associations between oral contraceptives (OCs) use and depression have been conflicting. Insight into the impact of analytical choices on the association may help to reconcile previous heterogeneous findings.

Objectives: We aimed to examine the association between adolescent OC use and subsequent depression risk in early adulthood analyzing all theoretically justifiable models.

Methods: Women from the prospective cohort study Tracking Adolescents’ Individual Lives Survey (TRAILS) were included in this study. All justifiable associations between adolescent OC use (ages 16-19 years) and major depressive disorder (MDD) in early adulthood (ages 20-25 years) as assessed by the Diagnostic and Statistical Manual of Mental Disorders-IV oriented Lifetime Depression Assessment Self-Report and the Composite International Diagnostic Interview were tested.

Results: A total of 818 analytical models were analyzed in 534 adolescent OC users and 191 nonusers. Overall, there was a tentative association of adolescent OC use and an episode of MDD in early adulthood (median odds ratio \([OR]_{\text{median}}=1.41\); \(OR_{\text{min}}=1.08; OR_{\text{max}}=2.18\), permutation testing \(p\)-value 1 = .052, and \(p\)-value 2 = .046), which was primarily driven by the group of young women with no history of MDD (\(OR_{\text{median}}=1.72; OR_{\text{min}}=1.21; OR_{\text{max}}=2.18\), both permutation testing \(p\)-values = .02).

Conclusions: Adolescent OC use was associated with an increased risk for experiencing an episode of MDD, but only among women with no history of MDD in adolescence. Understanding the potential side effects of OCs will help women and their doctors make informed choices when deciding among possible methods of birth control.

Exploring predictors of depressive symptoms in patients with multiple sclerosis: The effect of neuropathic pain, shame, and mindfulness

T. Carvalho¹,², L. Benedito¹ and C. Gomes³

¹Psychology, Instituto Superior Miguel Torga, Coimbra, Portugal; ²Faculit Of Psychology And Educational Sciences, University Of Coimbra, Center For Research in Neuropsychology and Cognitive-Behavioral Intervention (CINEICC), Coimbra, Portugal and ³Clinicia de Saúde Psiquiátrica de Coimbra – Casa da Oliveira, Coimbra, Portugal

doi: 10.1192/j.eurpsy.2021.307

Introduction: Multiple Sclerosis (MS) is a chronic inflammatory, immune-mediated, demyelinating disease of the central nervous system, with a progressive course. It is potentially disabling and affects mainly young adults. Depression is the mental disorder with the greatest comorbidity with MS and tends to worsen its symptomatology and course. However, knowledge about the predictors of depression in patients with MS is scarce.

Objectives: This preliminary study aimed to verify whether neuropathic pain (NP), internal (IS) and external (ES) shame and mindfulness predict depressive symptoms in patients with MS.

Methods: This cross-sectional study included a convenience sample of 95 patients diagnosed with MS and without other identified neurological diseases. Participants completed the Depression Subscale of the Depression, Anxiety and Stress Scales-21, the Analogue Pain Scale of the Pain Detect Questionnaire, the External and Internal Shame Scale, and the Mindfulness Subscale of the Self-Compassion Scale.

Results: All potential predictors exhibited significant correlations with depressive symptoms and significantly predicted this symptomatology in simple linear regression models. Thus, they were included as covariates in the multiple linear regression model. This model explained a high percentage of the variance of depressive symptoms (40.5%) and identified NP, IS and mindfulness as significant predictors.

Conclusions: Interventions aimed at preventing/reducing depression in patients with MS should minimize IS and develop mindfulness and NP coping skills, in order to promote mental health in this target population and possibly prevent the exacerbation and progression of MS symptomatology.

Introduction: Baseline EEG correlates of responders/non-responders to combined antidepressive treatment including transcranial magnetic stimulation

Disclosure: No significant relationships.

Keywords: Baseline EEG; antidepressive treatment; transcranial magnetic stimulation
Introduction: Use of combined antidepressive treatment included high-frequency rhythmic transcranial magnetic stimulation (rTMS) of the left dorsolateral prefrontal cortex (DLPFC) is one of the ways for overcoming of pharmaco-resistance in depressive patients.

Objectives: The aim of the study was the search for possible EEG predictors of antidepressive effects of rTMS of the left DLPFC in combined treatment of depression.

Methods: 30 female in-patients (F31.3, F33.0, F33.1, by ICD-10; combined treatment of depression. To identify such reward dynamics and use them to predict future reward anticipation (wanting), and active behavior (engaging).

Objective: The aim of the study was the search for possible EEG predictors of antidepressive effects of rTMS of the left DLPFC in combined treatment of depression.

Methods: 30 female in-patients (F31.3, F33.0, F33.1, by ICD-10; combined treatment of depression. To identify such reward dynamics and use them to predict future reward anticipation (wanting), and active behavior (engaging).

Objectives: The aim of the study was the search for possible EEG predictors of antidepressive effects of rTMS of the left DLPFC in combined treatment of depression.

Methods: 30 female in-patients (F31.3, F33.0, F33.1, by ICD-10; combined treatment of depression. To identify such reward dynamics and use them to predict future reward anticipation (wanting), and active behavior (engaging).

Objectives: We investigated whether at baseline (i) higher network positive affect in-strength, reflecting how strongly positive affect is influenced by other components and hence the level of anhedonia, and (ii) higher network connectivity, reflecting overall functioning of the reward system, are associated with fewer depressive symptoms on follow-up.

Methods: We used data from 43 participants with mild depressive symptoms from the SMARTSCAN study. The dynamic interplay between momentary positive affect, reward anticipation, and active behavior was assessed with individual vector-autoregressive models and the network analysis. Network positive affect in-strength and connectivity indices were used to predict a six-month depressive symptoms trajectory.

Results: Reward systems networks vary greatly between individuals. On the group level, higher positive affect in-strength (Beta=-3.66, p=0.05) and network connectivity (Beta=-4.06, p=0.03) at baseline were associated with fewer symptoms at follow-up.

Conclusions: Higher influences of reward anticipation and active behavior on positive affect and stronger connections between reward cycle components are associated with fewer future symptoms, suggesting the importance of daily life reward cycle dynamics in depression.

Disclosure: No significant relationships.

Potential of antithrombin III as a biomarker of antidepressive effect in major depressive disorder

R. Song* and Y. Shi

Department Of Neurology, Affiliated ZhongDa Hospital, School of Medicine, Southeast University, Nanjing, China

*Corresponding author.
doi: 10.1192/j.eurpsy.2021.310

Introduction: Previous study has identified increased antithrombin III (ATIII) in patients with major depressive disorder (MDD), supporting ATIII as a potential biomarker for depression diagnosis.

Objectives: This study aimed to reveal the alteration of ATIII after occipital repetitive transcranial magnetic stimulation (rTMS), and illuminate its power to evaluate and predict the curative effects in MDD treatment.

Methods: A total of 90 MDD patients were recruited and further intervened with rTMS in occipital for individualized, standard or sham treatment for five days. Those of 74 patients underwent entire detection, including clinical assessments, blood collection and protein measurement.

Results: After treatment, decreased ATIII were detected in both the individualized and the standard group (p<0.001 and 0.001, respectively) instead of the sham one. Especially, the reduction in ATIII in the individualized group was associated with improvements in several neuropsychological assessments. Besides, ATIII at baseline in the standard group and after the individualized rTMS showed high performance to evaluate or predict the response to the 5-day treatment (AUC=0.771, 95%CI, 0.571-0.971; AUC=0.875, 95%CI, 0.714-1.000, respectively) and the remission in follow-up (AUC=0.736, 95%CI, 0.529-0.943; AUC=0.828, 95%CI, 0.656-1.000, respectively). Furthermore, both baseline ATIII and change...
