The finite-size scaling functions for anisotropic three-dimensional Ising models of size $L_1 \times L_1 \times aL_1$ ($a$: anisotropy parameter) are studied by Monte Carlo simulations. We study the $a$ dependence of finite-size scaling functions of the Binder parameter $g$ and the magnetization distribution function $p(m)$. We have shown that the finite-size scaling functions for $p(m)$ at the critical temperature change from a two-peak structure to a single-peak one by increasing or decreasing $a$ from 1. We also study the finite-size scaling near the critical temperature of the layered square-lattice Ising model, when the systems have a large two-dimensional anisotropy. We have found the three-dimensional and two-dimensional finite-size scaling behavior depending on the parameter which is fixed; a unified view of 3D and 2D finite-size scaling behavior has been obtained for the anisotropic 3D Ising models.

I. INTRODUCTION

Finite-size scaling (FSS) has been increasingly important in the study of critical phenomena [1-4]. This is partly due to the progress in the theoretical understanding of finite-size effects, and partly due to the application of FSS in the analysis of simulational results.

Recently, more attention has been paid to the universality of FSS functions [5-7] for both percolation models [6-7] and Ising models [8-10]. It has been shown that several quantities including distribution functions on various lattices have universal FSS functions by choosing appropriate metric factors. It should be noted that universal FSS functions depend on boundary conditions and the shape of finite systems.

In the percolation problem, it was considered until a quite recent time that there exists only one percolating cluster on two-dimensional (2D) lattices at the percolating threshold. But the importance of the number of percolating clusters for anisotropic systems, which was pointed out by Hu and Lin [11], has captured current interest [12-13]. Aizenman [14] derived the upper and lower bounds of the probability for the appearance of $n$ percolating clusters, $W_n$, for 2D percolation at criticality. His result was later confirmed by Monte Carlo simulations [15]. By use of conformal field theory, Cardy [16] proposed an exact formula for $W_n$ at the percolation threshold for the systems with large aspect ratios [17]. The aspect ratio $L_1/L_2$ is an important quantity in the FSS functions for anisotropic 2D systems of size $L_1 \times L_2$.

The “nonuniversal scaling” of the low-temperature conductance peak heights for Corbino disks in the quantum Hall effect has been discussed in terms of the number of the percolating clusters [18].

For the Ising model, the aspect ratio dependence of Binder parameter [19] at the critical temperature was studied by Kamieniarz and Blöte [20]. Binder and Wang discussed anisotropic FSS [21]. The aspect ratio dependence of the universal FSS functions for Binder parameter and magnetization distribution function was discussed by Okabe et al. [22] for the 2D Ising model with tilted boundary conditions. For fixed set of the aspect ratio and the tilt parameter, the FSS functions were shown to be universal [23]. Quite recently, based on the connection between the Ising model and a correlated percolation model, Tomita et al. [24] studied the FSS properties of distribution functions for the fraction of lattice sites in percolating clusters in subgraphs with $n$ percolating clusters, $f_n(c)$, and the distribution function for magnetization in subgraphs with $n$ percolating clusters, $p_n(m)$. They studied the change of the structure of the magnetization distribution function for the 2D system with large aspect ratio in terms of percolating clusters.

Almost all results above for the shape effects on FSS functions are for 2D systems except for some works on percolation problem [25-26]. It is quite important to extend these arguments for higher-dimensional systems. Conformal invariance plays a role in 2D systems [27] but is not so powerful for three-dimensional (3D) systems as for 2D ones. Moreover, there are two limiting cases for anisotropic 3D systems, that is, the one-dimensional (1D) limit and the 2D limit. It is interesting to study various types of scaling for anisotropic 3D systems.

In this paper, we study the FSS functions for anisotropic 3D systems by Monte Carlo simulations. We are concerned with the ferromagnetic Ising model on the $L_1 \times L_1 \times aL_1$ simple cubic lattices with the periodic boundary conditions, where $a$ is regarded as the anisotropy parameter. Attention is mainly paid to the effect of anisotropy, and we study the $a$ dependence of the FSS functions for quantities such as the Binder parameter and the magnetization distribution function.
At the critical temperature for the 3D Ising model, we find that FSS functions for the magnetization distribution function change from a two-peak structure to a single-peak one, when the anisotropy parameter $a$ is varied from 1. This behavior is observed both for the systems with 2D anisotropy and for those with 1D anisotropy. When a system has a large 2D anisotropy, we find that finite-size systems with fixed anisotropy parameter show good FSS behavior as 3D systems near the critical temperatures for the layered square-lattice Ising models. In contrast, when we fix a number of layers and apply the FSS analysis for layered systems, these systems are scaled as 2D ones.

We organize the rest of the paper as follows. In Sec. 2, we define the FSS functions and describe the quantities we treat in this paper. In Sec. 3, we present our simulational results. In Sec. 4, our results are summarized and discussed.

II. FINITE-SIZE SCALING

If a quality $Q$ has a singularity of the form $Q(t) \sim t^\omega$ ($t = T - T_c$) near the criticality $t = 0$, then the corresponding quantity $Q(L, t)$ for finite systems with the linear size $L$ has a following scaling form,

$$Q(L, t) \sim L^{-\omega/\nu} f(tL^{1/\nu}),$$

where $\nu$ is the correlation-length critical exponent and $f(x)$ is the scaling function. Of course, the corrections to FSS are not negligible for smaller $L$. The FSS is also applicable to the distribution function of $Q$. At the criticality $t = 0$, the FSS function has a following form,

$$p(Q; L, t = 0) \sim L^{\omega/\nu} F(QL^{\omega/\nu}).$$

In this paper we focus on the Binder parameter and the magnetization distribution function. The Binder parameter [13] is given by

$$g = \frac{1}{2} \left( 3 - \frac{\langle m^4 \rangle}{\langle m^2 \rangle^2} \right),$$

and serves as a measure of the non-Gaussian nature of the distribution function. The FSS functions for these quantities are given by

$$g(L, t) \sim g(tL^{1/\nu}),$$

$$p(m; L, t = 0) \sim L^{\beta/\nu} p(mL^{\beta/\nu}),$$

where $\beta$ is the magnetization exponent.

III. RESULTS

We use the Metropolis Monte Carlo method to simulate the ferromagnetic Ising model on $L_1 \times L_1 \times aL_1$ simple cubic lattices with different values of $L_1$ and $a$. We use the periodic boundary conditions.

First, we show the results for $a \leq 1$, that is, a 2D anisotropic case. We plot the temperature dependence of the Binder parameter $g$ for $a=1$, $1/2$, and $1/4$ of various sizes in Fig. 1(a). Error-bars are within the size of marks unless specified. We give the FSS plots in Fig. 1(b): $g$ is plotted as a function of $(T - T_c)L^{1/\nu}$. For $T_c$, $\beta$ and $\nu$, we use the numerically estimated values for the 3D Ising model [20], that is, $T_c = 4.5114$, $\beta = 0.320$ and $\nu = 0.625$. From now on, we represent the temperature in unit of $J$. From Fig. 1(b) we see that the FSS functions have $a$ dependence in 3D systems, which is similar to the case of 2D systems.
We can get more information on the $a$ dependence from the magnetization distribution function $p(m)$. In Fig. 2, we show the scaling plot of the magnetization distribution function $p(m)$ at $T = T_c$ for various sizes with different anisotropy parameters ($a \leq 1$). From the figure we find good FSS behavior and also a large $a$ dependence.

Next turn to the case of $a \geq 1$, that is, a 1D anisotropic case. We plot the temperature dependence of $g$ for $a=1$, 2, and 4 of various sizes in Fig. 3(a). The FSS plots are given in Fig. 3(b). We see similar behavior of the FSS functions for $a \geq 1$, that is, $g$ take smaller values if we change $a$ from 1.

Let us consider the origin of the $a$ dependence of FSS functions. This problem is related to the multiple percolating clusters. The connection between critical phenomena of spin models and percolation problems has been studied for a long time [21–23]. Quite recently, Tomita et al. [18] have used the cluster formalism to investigate the percolating properties of the 2D Ising model. They elucidated that the existence of several percolating clusters for anisotropic finite systems leads to the change of the structure of $p(m)$. That is, the combination of up-spin clusters and down-spin clusters gives the contribution of $m \sim 0$ in $p(m)$ for anisotropic case. The $a$ dependence of
$p(m)$ for the 3D systems can be understood in the same way as the 2D systems. We can apply this argument both cases for 2D anisotropy ($a < 1$) and 1D anisotropy ($a > 1$). The value of Binder parameter $g$ at $T = T_c$, of course, reflects upon the structure of the distribution function $p(m)$.

![FIG. 5. $g$ at $T = T_c$, $g_c$, as a function of $a$. We use a semi-logarithmic scale.](image)

In order to see the anisotropy parameter dependence more clearly, we plot the $a$ dependence of the Binder parameter $g$ at criticality, $g_c$, in Fig. 5. Here, we use the semi-logarithmic scale for plot. We add several data other than those given in Figs. 1 and 3. For large enough $a$ or small enough $a$, the corrections to FSS become larger. From Fig. 5, we find that $g_c$ takes the maximum value at $a = 1$ and decreases gradually in both directions, $a < 1$ and $a > 1$. For very large $a$ or very small $a$, $g_c$ tends to vanish, which indicates that the distribution function $p(m)$ approaches the Gaussian distribution. This behavior is consistent with above-mentioned multiple-percolating-cluster argument. Such an $a$ dependence of $g$ at criticality for 2D anisotropy of 2D Ising model was already discussed for 2D Ising model [10].

It is also interesting to consider the relation to the layered square-lattice Ising model for the case of large 2D anisotropy. The critical temperatures and the shift exponent for the layered square-lattice Ising model were studied by Kitatani et al. [24]. In Fig. 6, we give the temperature dependence of $g$ for several lattices, where the number of layers, $s$, is 4, 6, and 8. If we make the system size large with fixing $s$, the system becomes the layered square-lattice Ising model. We can estimate the $s$-dependent critical temperature $T_{cs}$ from the crossing point of the curves for fixed $s$ in Fig. 6. Our estimates, $T_{cs} = 4.2364(4)$, $T_{cs} = 4.3701(4)$, and $T_{cs} = 4.4222(4)$, are consistent with those of Ref. [24].

![FIG. 6. Temperature dependence of $g$ for several systems. The numbers of layers are 4, 6, and 8.](image)

Picking up the data for $a = 1/16$ from Fig. 5, we plot $g$ as a function of $(T - T_{cs})L^{1/\nu}$ in Fig. 7. Here we treat $T - T_{cs}$ for each $s$, and $\nu$ is chosen as 0.625, that is, the 3D value. We have good FSS behavior in Fig. 7, but this FSS plot is different from that given in Fig. 1(b), where $T - T_c$ has been treated. We should note that $T - T_{cs}$ can be rewritten as $T - T_{cs} = (T - T_c) + (T_c - T_{cs})$, and $T_c - T_{cs} \propto s^{-\lambda}$. Here $\lambda$ is the shift exponent and is shown to be $1/\nu_{3D}$ [24]. Thus, for fixed $a$, we have 3D FSS for $T - T_{cs}$. In this case, the value of $g_c$ at $T = T_{cs}$ is $\sim 0.92$, which is nothing but the $g_c$ value for the isotropic 2D Ising model. It is different from $\sim 0.04$ for $g_c$ value of anisotropic 3D Ising model for $a = 1/16$, which is given in Fig. 5. In Fig. 8, we also show the scaling plot of the magnetization distribution function $p(m)$ at $T = T_{cs}$ for each $s$, fixing $a$ as $1/16$. We have good FSS behavior.
using 3D exponents. There are two distinct peaks in $p(m)$, which is a typical character of $p(m)$ at $T_c$ for the isotropic 2D Ising model. In contrast, if we pick up the data for fixed $s$, for example, $s = 6$, these systems are expected to be scaled by using 2D critical exponents. Since we fix $s = aL_1$, the scaled variable is given by $(T - T_{cs})L_1^{1/\nu}$. Using the 2D exponent, $\nu_{2D} = 1$, we get very good scaling plot, shown in Fig. 8. Of course, the critical value $g_c$ at $T = T_{cs}$ is $\sim 0.92$, that is, the $g_c$ value for the isotropic 2D system.

IV. SUMMARY AND DISCUSSIONS

To summarize, we have studied the FSS functions for anisotropic 3D Ising model by Monte Carlo simulations. The anisotropy parameter ($a$) dependence of the FSS functions for the Binder parameter and the magnetization distribution function has been investigated. We have shown that the magnetization distribution functions change from two-peak structures to single-peak ones as $a$ increases or decreases from 1. This change of distribution functions may be attributed to the combination of up-spin percolating clusters and down-spin percolating clusters for anisotropic systems, which is the same as the case of 2D systems [15]. We should also note that the distribution function $p(m)$ approaches the Gaussian distribution for large anisotropy, which is another indication of the multiple-percolation-cluster argument. It is interesting to calculate the probability for the appearance of $n$ percolating clusters, $W_n$, for the anisotropic 3D Ising model and to make cluster analysis, which will be left to a future study.

Moreover, we have considered the relation to the layered square-lattice Ising models for large 2D anisotropy. We have obtained 3D FSS behavior near the critical temperature of the layered square-lattice Ising models, $T_{cs}$, for fixed $a$. In contrast, when we fix the number of layers, we have shown 2D FSS behavior near $T_{cs}$. Thus, we have obtained a unified view of 3D and 2D FSS behavior for the anisotropic 3D Ising models.

We have studied the shape effects of FSS functions for 3D Ising models. FSS functions also depend on boundary conditions. Extension of the 2D results for various boundary conditions, for example, tilted boundary conditions [10], to 3D systems will be interesting. This study is now in progress.

ACKNOWLEDGMENTS

We would like to thank C.-K. Hu and Y. Tomita for valuable discussions. The computation in this work has been done using the facilities of the Supercomputer Center, Institute for Solid State Physics, University of Tokyo. This work was supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science, Sports and Culture, Japan.
