1. Introduction

Liver inflammation is a common response to various types of chronic liver injury. In the initial stages of inflammation, hepatocytes, Kupffer cells, platelets, and leukocytes are activated and produce reactive oxygen species (ROS) and inflammatory mediators such as platelet-derived growth factor, transforming growth factor-β (TGF-β), connective tissue growth factor, and tissue necrosis factor-α (TNF-α). These factors probably act as paracrine mediators to activate quiescent hepatic stellate cells (HSCs) that are localized in the perisinusoidal space, resulting in abnormal quantity and composition of extracellular matrix [1], which in turn leads to hepatitis, liver fibrosis, and cirrhosis. Thus, it is important to suppress hepatic inflammation in the early stages of liver fibrosis.

Oxidative stress, in particular, lipid peroxidation, has been considered one of the major causes of liver damage and has been reported to be associated with HSC activation [2]. Lipid peroxidation may provoke liver damage by compromising the integrity of membranes and by inducing covalent binding of reactive intermediates to important antioxidants such as glutathione [3]. Antioxidants are potent free radical scavengers and have been documented to protect hepatocytes from lipid peroxidation in the carbon tetrachloride- (CCl₄-) or dimethylnitrosamine- (DMN-) induced liver injury models [4, 5]. Therefore, blocking or retarding the reactions of lipid peroxidation and the inflammatory process by antioxidants could be a promising therapeutic intervention for prevention or treatment of liver injuries.

Dietary phytochemicals of fruits, vegetables, whole grains, and other plant foods were shown to have potent...
antioxidant activity, and the mixture or combination of phytochemicals was proposed to be responsible for their strong antioxidant activity [6]. In most cases, the poor absorption rate of polyphenolic substances limits their use as dietary supplements in human. Particularly, many polyphenols exist in polymeric forms of high molecular weight that may further decrease their bioavailability [7]. Oligonol is a phenolic product derived from lychee fruit (*Litchi chinensis* Sonn.) extract by a manufacturing process that converts polyphenol polymers into oligomers. Oligonol comprises 16.0% monomers (catechin, epicatechin, epicatechin gallate, and epigallocatechin gallate), 13.9% dimers (procyanidin A1, A2, B1, and B2), and oligomers of proanthocyanidins [8]. Oligonol delivers higher levels of oligomeric procyanidins compared with fruit and plant sources that contain high molecular weight procyanidins [7].

There is a growing evidence that oligonol can elicit some physiological and biochemical alterations in vitro and in vivo, such as inhibition of adipogenesis in 3T3-L1 adipocytes [9], improvement of memory and cognition under an amyloid beta-induced Alzheimer’s mouse model [10], the induction of improvement of memory and cognition under an amyloid physiological and biochemical alterations in vitro [11], and antioxidant and anti-inflammatory effects [11], and antioxidant and anti-inflammatory effects on acute liver inflammation induced CCl4 [12]. However, apoptosis in MCF-7 and MDA-MB-231 human breast cancer beta-induced Alzheimer’s mouse model [10], the induction of apoptosis in MCF-7 and MDA-MB-231 human breast cancer cell lines [11], and antioxidant and anti-inflammatory effects in ultraviolet B-(UVB-) irradiated mouse skin [12]. However, the potential protective activity and mechanism of oligonol on acute liver inflammation induced CCl4 have not yet been conducted.

Here, we report that oral administration of oligonol exerts an antioxidant, anti-inflammatory, and hepatoprotective effect in CCl4-induced acute liver injury in rats. The possible molecular mechanism of action of oligonol was explored by analyzing the expression of nuclear factor-kappa B (NF-κB), TNF-α, IL-1β, cyclooxygenase-2 (COX-2), inducible nitric oxide synthase (iNOS), Akt, and mitogen-activated protein kinases (MAPKs), including extracellular signal-regulated kinase (ERK), c-Jun NH2-terminal kinase (JNK), and p38.

2. Materials and Methods

2.1. Chemicals. Bicinchoninic acid (BCA) solution, bovine serum albumin (BSA), *t*-butyl hydroperoxide (*t*-BHP), butylated hydroxytoluene (BHT), CCl4, 1,1-diphenyl-2-picrylhydrazyl (DPPH), formalin, sodium carboxymethylcellulose (CMC), 2′,7′-dichlorofluorescin diacetate (DCFDA), phosphoric acid, trichloroacetic acid (TCA), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromides (MTT), and Trolox were obtained from Sigma-Aldrich Co. 2-Thiobarbituric acid (TBA) was obtained from Tokyo Chemical Industry Co. Malondialdehyde (MDA) tetrabutylammonium salt was obtained from Fluka. Oligonol is commercially available (Amino Up Chemical Co., Ltd., Sapporo, Japan).

2.2. DPPH Assay. The scavenging activity of oligonol was measured using the stable DPPH free radical, according to a published method [13] with slight modifications. The reaction mixture contained 50 mM phosphate buffer at pH 7.4 (80 μL), 100 μM DPPH dissolved in ethanol (100 μL), and the indicated concentrations of oligonol and Trolox (20 μL). Triplicate reaction tubes were wrapped in aluminum foil and placed at room temperature for 30 min in the dark. Spectrophotometric readings were taken at 517 nm using a microplate reader (Apollo-LB913, Berthold Technologies). The percent inhibition of free radical production was calculated from ([A0 – (A – A0)]/A0) × 100, where A0 is the absorbance of the control, A is the absorbance of the sample, and A0 is the absorbance of the blank sample (containing all reagents except DPPH). IC50 values were obtained from the inhibition curves.

2.3. Antioxidative Activity against Lipid Peroxidation Induced FeSO4/H2O2 in Rat Liver Homogenates. Lipid peroxidation in rat liver homogenates induced by the Fenton reaction, comprising 0.1 mM FeSO4, 3 mM H2O2, various concentrations of the tested substances, and liver homogenates (7.5 mg protein/mL), was measured by the method of Buege and Aust [14] with some modifications. The reaction was started by the addition of FeSO4 and H2O2 and then incubated at 37°C for 10 min. The reaction was stopped by mixing with 3 mL of a stock solution of 15% (w/v) TCA, 0.375% (w/v) BHA, 0.125 M hydrochloric acid, and 0.6 M BHT. The combination of reaction mixture and stock solution was heated for 30 min in a boiling water bath. After cooling, the flocculent precipitate was removed by centrifugation at 1,250 g for 20 min. The absorbance of the supernatant was determined at 532 nm, and the MDA concentration was calculated using MDA tetrabutylammonium salt as a standard. Protein concentrations were determined by the BCA assay using BSA as the reference standard.

2.4. Protective Effect of Oligonol on Cell Damage Induced by t-BHP. The human hepatocellular carcinoma cell line HepG2 was purchased from the Korean Cell Line Bank. The cells were cultured in a complete medium composed of Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine serum (FBS), 1% glutamine, penicillin (100 μg/mL), and streptomycin (100 μg/mL) at 37°C in a 5% CO2 humidified incubated environment. The cells were placed in 96-well plates at a density of 2.0 × 105 cells per well. After 24 h cultivation, the complete medium of the plates was replaced with serum-free medium, and various concentrations of oligonol (0.5, 2, 5, and 10 μg/mL) were added to the cells. Four hours later, the cells were exposed to 300 μM t-BHP for 3 h. After incubation, 100 μL of MTT solution (1 mg/mL in phosphate buffered saline) was added to each well and incubated for another 2 h. After the culture medium had been removed, 100 μL of DMSO was added and mixed to dissolve the MTT formazan crystals. The plates were read on a microplate reader (Apollo-LB913, Berthold Technologies) using a wavelength of 540 nm. The survival values, used to examine the protective effects of the compounds against cell damage by t-BHP, were expressed as a percentage of the absorbance of the normal cells.

2.5. Cell Lysis. Cells were washed by phosphate buffered saline (PBS), and then 1 mL of ice-cold PBS was added.
Pellets were harvested at 1,000 g at 4°C for 3 min. The pellets were suspended in ProEX CETi Lysis Buffer (TransLab), incubated on ice for 20 min and then centrifuged at 14,000 g at 4°C for 10 min. The supernatants were used as total protein extraction.

2.6. Animals. Male Sprague-Dawley rats were obtained from Samtako (Osan, Korea). Animals were provided standard rat chow with free access to tap water and were maintained at a controlled temperature (23 ± 3°C) and humidity (50 ± 20%) with a 12 h light-dark cycle. With respect to ethical issues and scientific care, the animal protocol used in this study was reviewed and approved by the Pusan National University-Institutional Animal Care and Use Committee (PNU-IACUC; Approval number PNU 2008-0541).

2.7. Induction of Acute Hepatic Inflammation with CCl₄. Twenty-four rats weighing 140–160 g and 5-6 weeks in age were assigned to 4 groups (n = 6): control, CCl₄, Oli10, and Oli50. Animals in the control group received olive oil (CCl₄ vehicle) by intraperitoneal (i.p.) injection and CMC (oligomol vehicle) by oral gavage; the CCl₄ group received CCl₄ and CMC, while the Oli10 and Oli50 group received CCl₄ and oligonol at 10 and 50 mg/kg/day, respectively. Liver injury was induced by a single i.p. injection of 25% (w/v) CCl₄ (0.6 g/kg body weight) in olive oil. Oligonol was suspended in 0.5% CMC solution to a concentration of 10 and 50 mg/mL and administered by oral gavage twice, once at 16 h and once at 30 min before CCl₄ intoxication. Twenty-four hours after the CCl₄ injection, all rats were euthanized by ether anesthesia, and the livers were excised and weighed. Blood samples for biochemical analyses were obtained from the inferior vena cava.

2.8. Liver Homogenate Preparation. The remaining liver tissue was rapidly cut into small pieces and homogenized with two volumes (w/v) of ice-cold potassium phosphate buffer (pH 7.4) using an IKA T10 basic Ultra-Turrax homogenizer. Debris and nuclei were removed from the homogenate by centrifugation at 700 × g at 4°C for 10 min and stored at −80°C for further analysis.

2.9. Histology. Liver specimens were fixed by immersion in 10% neutral buffered formaldehyde solution (NBF) for 24 h and then washed overnight. The samples from each group (n = 6) were dehydrated in a graded series of ethanol solutions, cleared in xylene, and embedded in paraffin. Eight to ten tissue sections (6 μm thick) were cut and stained with hematoxylin and eosin (H&E) to assess the architectural alterations. The degree of liver damage was evaluated semiquantitatively using the Ishak system under a light microscope [15].

2.10. Biochemical Analysis of Liver Enzymes. Serum aspartate transaminase (AST) and alanine transaminase (ALT) activities were measured using the method described by Reitman and Frankel [16], using AST/ALT kits (Asan Chemical Co.).

2.11. Determination of MDA Content. MDA levels in the liver tissue were measured by a published method with modifications [17]. Standards were prepared via serial dilution of a stock solution of 10 μM MDA tetrabutylammonium salt in distilled water. For the assay, 10 mg of liver tissue was homogenized with 1 mL of solution containing 26 mM TBA, 0.64 mM BHT, 0.93 M TCA, and 11 mM hydrochloric acid. The homogenates were heated for 1 h in a boiling water bath. After cooling, tubes were centrifuged for 15 min at 2,000 g. The absorbance of supernatant was determined at 532 nm and the MDA concentration was calculated using MDA tetrabutylammonium salt as a standard.

2.12. Measurement of ROS Level. A fluorometric assay was used to determine levels of ROS, such as ·O2, ·OH, and H₂O₂. Nonfluorescent DCFDA was oxidized to the highly fluorescent 2′,7′-dichlorofluorescin (DCF) in the presence of esterases and ROS, including lipid peroxides [18]. For the assay, 50 μM DCFDA was added to liver homogenates for 250 μL of final volume. Changes in fluorescence intensity were measured every 5 min for 30 min on a fluorescence plate reader, GENios (Tecan Instrument, Salzburg, Austria), with excitation and emission wavelengths set at 485 and 530 nm, respectively.

2.13. RNA Extraction and Reverse Transcriptase-Polymerase Chain Reaction (RT-PCR). Total RNA was extracted from samples of 100 mg of frozen liver by homogenization in Trizol reagent (Invitrogen). RNA purity was assessed by the absorbance ratio at 260 nm and 280 nm. cDNA was prepared from samples of 100 mg of frozen liver by homogenization in Trizol reagent (Invitrogen). RNA purity was assessed by the absorbance ratio at 260 nm and 280 nm. cDNA was prepared from samples of 1 μg of RNA with iScript cDNA Synthesis Kit (Bio-Rad, Hercules, CA, USA) according to the protocol provided by the manufacturer. PCR was performed in 20 μL of reaction solution containing 1 μg of cDNA and the appropriate primers from Bioneer (Daedeon, Korea) (Table 1) using a Promega GoTaq Flexi DNA Polymerase PCR kit. PCR conditions were as follows: denaturation at 95°C for 10 min, 35 cycles of 30 s at 95°C, 90 s at 60°C, 60 s at 72°C, and a final extension at 72°C for 5 min. GAPDH was measured as an internal control for normalization of mRNA levels. The amplified products were analyzed by 1.5% agarose gel electrophoresis and visualized by ethidium bromide staining under UV light illumination (Gel Doc/ChemiDoc imager, Azure). All reactions were performed in triplicate.

2.14. Western Blotting Analysis. Nuclear extracts, cytosol extracts, or total proteins of liver tissue were prepared as a published method with modification [19]. The protein concentration was measured by the BCA assay. Aliquots of protein (30 μg) were denatured at 95°C for 5 min before electrophoresis on 10% SDS-polyacrylamide gel. After transfer to a polyvinylidene difluoride (PVDF) membrane (Millipore), the blot was blocked with 5% nonfat milk solution for 1 h at room temperature and then incubated with a 1:1,000 dilution of primary antibodies selective against either NF-κB p65, total JNK, p-JNK, total ERK, p-ERK, total Akt, p-Akt, total p38, p-p38, histone, or β-actin (Santa Cruz Biotechnology) in Tris-buffered saline Tween-20 (TBST) at 4°C overnight,
followed by 1 h at room temperature. The membrane was washed 3 times for 5 min each with TBST solution. The membranes were incubated with 1:10,000 dilution of horseradish peroxidase-conjugated rabbit or mouse secondary antibodies (Santa Cruz Biotechnology) at room temperature for 1 h. The transferred proteins were visualized with an enhanced chemiluminescence (ECL) detection system and the band intensities were determined using a Gel Doc/ChemiDoc imager (Azure). The protein concentration was determined with a BCA protein assay kit (Pierce, Rockford, IL, USA).

2.15. Statistical Analyses. All results are expressed as the mean ± SE of the indicated number of replicates. Data were analyzed for statistical differences by one-way analysis of variance (ANOVA). A p value of 0.05 or less was considered statistically significant.

3. Results

3.1. Antioxidative Activities of Oligonol against the Lipid Peroxidation of Rat Liver Homogenates Induced by FeSO\(_4\) and \(H_2O_2\) and against DPPH Radical. The antioxidant activities of oligonol were investigated by the examination of the inhibitory effect against FeSO\(_4\)/H\(_2O_2\)-induced lipid peroxidation in rat liver homogenates (Table 2) and the DPPH radical scavenging effect (Table 3). As positive control for the inhibition of lipid peroxidation, a well-known antioxidant BHT was tested. Under the reaction condition which allows the IC\(_{50}\) of BHT to be 15.01 μM, IC\(_{50}\) of oligonol was 15.15 μM/L. Oligonol showed DPPH free radical scavenging activity (IC\(_{50}\) = 50.5 μg/mL) and Trolox was tested as a positive control (IC\(_{50}\) = 18.6 μM).

3.2. Hepatoprotective Effect of Oligonol against Cell Damage Induced by t-BHP. t-BHP is a cytotoxic agent that is metabolized to free radicals including \(t\)-butoxy, \(t\)-butylperoxy, or methyl radical that interfere with cellular functions. The protective effect of oligonol on cell damage induced by t-BHP was examined (Figure 1). By exposing the cells to 300 μM t-BHP for 3 h, cell viability decreased to 46%. However, oligonol was found to protect cell damage dose-dependently, and the EC\(_{50}\) was calculated to be 0.25 μg. In addition, we investigated the effect of oligonol of TNF-\(\alpha\): tumor necrosis factor-alpha; IL-1\(\beta\): interleukin-1 beta; COX-2: cyclooxygenase-2; iNOS: inducible nitric oxide synthase; GAPDH: glyceraldehyde-3-phosphate dehydrogenase.
on the induction of proinflammatory mediator COX-2 in t-
BHP-treated HepG2 cells at the protein level by western blot
analysis. As shown in Figure 2, oligonol suppressed the t-
BHP-induced COX-2 induction.

3.3. Changes in Body and Liver Weight and Serum Parameters in Rats Intoxicated by CCl_{4}. Treatment with CCl_{4} caused
a slight increase in the ratio of body weight/liver weight when compared with the control group (Table 4). In contrast,
animals injected with CCl_{4} and orally administered with
oligonol showed significantly reduced ratios of liver weight
to body weight, compared to untreated animals injected
with CCl_{4}. These results indicate that oligonol reduces the
ratios of body to liver weight induced by CCl_{4} intoxication.
Biochemical analyses of serum AST and serum ALT activities
were performed to determine whether oligonol protected
the liver from CCl_{4}-induced injury (Figures 3(a) and 3(b)).
Serum AST and serum ALT levels were significantly higher in
rats injected with CCl_{4} (475.1 ± 330.3 and 160.0 ± 120.6 U/L, resp.) than in the control rats (35.5 ± 5.2 and 28.4 ± 4.3 U/L, resp.). Serum AST and serum ALT activities were signifi-
cantly reduced by oral administration of oligonol at both 10
and 50 mg/kg doses; levels of AST and ALT in the Oli10 group
were 193.7 ± 61.7 and 72.9 ± 26.0 U/L, respectively, and levels
in the Oli50 group were 121.1 ± 29.4 and 44.2 ± 17.6 U/L, respectively.

3.4. Prevention of ROS Production and Lipid Peroxidation by Oligonol. To assess the overall oxidative status, total ROS
was measured with DCFDA probe in the liver homogenates.
Results show that increased ROS levels with CCl_{4} intox-
cation were suppressed by the administration of oligonol
(Figure 4(a)). Induction of lipid peroxidation by CCl_{4} was
measured by the production of MDA in liver tissues (Fig-
ure 4(b)). The MDA content in the livers of CCl_{4}-treated rats
was significantly higher than that in the control animals but
significantly reduced in the livers of rats treated with oligonol
in a dose-dependent manner, which is consistent with the
results of ROS production and the liver function tests.

3.5. Liver Histopathology. The effect of oligonol on CCl_{4}-
hinduced histopathological changes in the liver was evaluated
on H&E stained liver sections (Table 5). Livers of the control
group showed normal lobular architecture with central veins
and radiating hepatic cords. No histological abnormalities
were observed (Figure 5(a)). In contrast, the liver sections
from CCl_{4}-treated animals showed distorted tissue archi-
tecture, submassive necrosis, vacuolization, and macroves-
cular fatty changes of hepatocytes (Figure 5(b)). Notably,
these pathologic changes were markedly reduced dose-
dependently in the livers of animals treated with oligonol
(Figures 5(c) and 5(d)).

Table 4: Effects of oligonol on body and liver weights of rats treated with CCl_{4}.

|               | Body weight (g) | Liver weight (g) | Ratio (%) |
|---------------|----------------|-----------------|-----------|
| Control       | 154.02 ± 7.40  | 5.96 ± 1.25     | 3.85      |
| CCl_{4}       | 158.01 ± 7.29  | 7.69 ± 0.66**   | 4.87      |
| Oli10         | 158.16 ± 4.62  | 6.98 ± 0.34*    | 4.42      |
| Oli50         | 156.75 ± 10.05 | 6.71 ± 0.29#    | 4.29      |

CCl_{4} alone treated group; Oli10: oligonol (10 mg/kg) with CCl_{4}; Oli50: oligonol (50 mg/kg) with CCl_{4}. *Values are expressed as the ratios of liver weight to body weight. Data are the mean ± SE of n = 6 rats/group. **p < 0.01 compared with the control group and #p < 0.05 compared with the CCl_{4} group.
Figure 3: Measurements of serum ALT and serum AST levels. Groups are as described in "Methods." Values are mean ± SE of n = 6 rats/group. **P < 0.01 and ***P < 0.001 compared with the control group and ##P < 0.01 and ###P < 0.001 compared with the CCl_4 group.

Figure 4: Effect of oligonol on ROS and MDA levels in rat liver intoxicated with CCl_4. ROS generation was measured by DCF formation with a fluorescent probe, DCFDA. Effect of oligonol on CCl_4-induced lipid peroxidation activity from the liver was measured by the method of Buege and Aust. Values are mean ± SE of n = 6 rats/group. **P < 0.01 and ***P < 0.001 compared with the control group.

Table 5: Effects of oligonol on the histopathological score of liver of CCl_4-treated rats.

| Group  | Number | Histopathological score of liver |
|--------|--------|---------------------------------|
|        |        | 0  | 1  | 2  | 3  | 4  |
| Control| 6      | 0  | 0  | 0  | 0  | 0  |
| CCl_4  | 6      | 0  | 0  | 0  | 1  | 5  |
| Oli10  | 6      | 1  | 2  | 1  | 2  | 0  |
| Oli50  | 6      | 3  | 1  | 1  | 1  | 0  |

3.6. Expression of TNF-α, IL-1β, COX-2, and iNOS mRNA. Expression of mRNA of proinflammatory cytokines TNF-α and IL-1β and proinflammatory proteins COX-2 and iNOS in the liver was measured by RT-PCR. Following agarose gel electrophoresis of reaction products, mRNA levels were quantified by normalization against the expression of the housekeeping gene, GAPDH. CCl_4 treatment increased the expression of TNF-α, IL-1β, COX-2, and iNOS mRNA in the liver, but these were dose-dependently and significantly reduced by pretreatment of rats with oligonol (Figures 6 and 7).

3.7. NF-κB Translocation to the Nucleus. The protein level of transcription factor NF-κB was examined. Activation of NF-κB was based on the detection of its translocation into cell nuclei from its initial location in the cytoplasm where it exists in an inactive form. Western blotting of NF-κB p65 protein in nuclear and cytosolic fractions of the liver tissues indicates that CCl_4 treatment exhibited an enhancement of nuclear NF-κB and a reduction of cytosolic NF-κB (Figure 8). Oligonol treatment to CCl_4-intoxicated rat markedly inhibited CCl_4-induced increase of NF-κB in the nuclear fraction of the liver. It also abrogated the reduction of NF-κB in the cytosolic fraction. The relative level of NF-κB p65 in the nuclear and cytosol is compared with β-actin and histon, respectively, and quantified by image analysis.
Figure 5: Effects of oligonol on CCl\textsubscript{4}-induced histopathological changes in rat livers. Representative H&E stained sections of livers of rats treated as described in methods. (a) Liver section of control group shows normal liver architecture, intact hepatocytes, and radiating hepatic cords from the central vein (CV); (b) CCl\textsubscript{4}-induced damage is indicated by distortion of the tissue architecture, submassive necrosis (thick arrows), fatty changes (thin arrows) in hepatocytes, and aggregations of inflammatory cells (arrowheads); (c) oligonol (10 mg/kg) plus CCl\textsubscript{4}; and (d) oligonol (50 mg/kg) plus CCl\textsubscript{4}. Oligonol treatment reduced the pathological alterations induced by CCl\textsubscript{4}. All images are original magnification ×400.

It showed that CCl\textsubscript{4}-treated rats had significantly increased expression of NF-κB p65 compared with the control animals. Moreover, the expression of NF-κB p65 in the oligonol-treated rats was reduced significantly in a dose-dependent manner. These results demonstrate that oligonol treatment in CCl\textsubscript{4}-intoxicated rats strongly inhibited the translocation of NF-κB from the cytosol to the nuclear fraction.

3.8. MAPKs and Akt Signaling Pathways Involved in NF-κB Activation. To investigate the molecular mechanism of NF-κB activation in the CCl\textsubscript{4}-intoxicated rat, we measured the expression levels of ERK1/2, JNK, and p38 MAPKs as well as Akt by using western blot analysis. The phosphorylation of MAPKs and Akt was increased in rats treated with CCl\textsubscript{4} alone as compared with the control group. However, treatment with low (10 mg/kg/day) and high (50 mg/kg/day) dose of oligonol in CCl\textsubscript{4}-intoxicated rats significantly decreased the expression levels of phosphorylated ERK1/2, JNK, and p38 MAPKs as well as Akt, in a dose-dependent manner (Figure 9).

4. Discussion

Oxidative stress, caused by the increased production of reactive oxygen species (ROS), is thought to be a key risk factor in the development of liver disease [20]. CCl\textsubscript{4} intoxication has been widely used as an experimental model of liver injury. CCl\textsubscript{4} is a substrate for cytochrome P450 2E1 (CYP2E1). It is converted to a CCl\textsubscript{3} radical, which generates CCl\textsubscript{3}OO' by reacting with molecular oxygen. Since CCl\textsubscript{3}OO' reacts with microsomal membranes and induces lipid peroxidation, membrane damage by free radical chain reaction has been postulated to be the primary cause of hepatocellular injury by this compound [21]. In CCl\textsubscript{4}-induced injury, antioxidants are widely known to be able to protect against hepatocyte necrosis because they intercept the CCl\textsubscript{4}-induced oxidative stress in hepatocytes by scavenging CCl\textsubscript{3} and lipid peroxyl radicals [22].

In this study, a single dose of CCl\textsubscript{4} induced distorted tissue architecture, submassive centrizonal necrosis, fatty changes, and inflammatory cell infiltration. However, these pathologic changes were significantly reduced by pretreatment of 10 and 50 mg/kg of oligonol dose-dependently. Treatment of oligonol effectively improved the CCl\textsubscript{4}-induced elevation in serum AST and serum ALT levels, indicating the hepatoprotective effects of oligonol against CCl\textsubscript{4} intoxication. CCl\textsubscript{4} treatment caused high levels of liver oxidative damage, as evidenced by a significant elevation of ROS production and MDA concentration in liver homogenates. However, oligonol markedly inhibits CCl\textsubscript{4}-induced oxidative stress in liver of rats in a dose-dependent manner.

Antioxidant activity of oligonol is well established in many studies [23], and the activities were consistent with the results that oligonol exerts the inhibitory effect against FeSO\textsubscript{4}/ H\textsubscript{2}O\textsubscript{2}-induced lipid peroxidation in rat liver homogenates and against the DPPH radical scavenging effects. In addition, the protective effect of oligonol via antioxidative
activity was assessed in t-BHP-induced HepG2 cell damage. HepG2 cells are considered a reasonable model for studying in vitro xenobiotic metabolism and liver toxicity since they maintain a majority of specialized functions similar to normal human hepatocytes [24]. The oxidant t-BHP is well known to induce oxidative stress [25]. Oligonol showed hepato protective effects against t-BHP-induced oxidative stress. Taken together, hepatoprotective effects of oligonol in CCl4-intoxicated rat model and in t-BHP-induced HepG2 cells may be due to the potent antioxidant and free radical scavenging activities of oligonol.

Proinflammatory cytokines such as TNF-α, IL-1β, and IL-6 have been the focus of investigations of inflammatory organ injury because the uncontrolled and prolonged action of these proteins is potentially harmful [26]. Considerable evidence suggests that TNF-α and IL-1β contribute to the pathogenesis of liver inflammatory diseases by activating the NF-κB signaling pathway [27], suggesting that it may be important to monitor proinflammatory cytokines when studying liver injury. In our study, we focused on the anti-inflammatory effect of oligonol by analyzing the expression of NF-κB p65, TNF-α, and IL-1β. Our data show that the production of TNF-α and IL-1β were significantly increased by CCl4-induced hepatotoxicity, which is consistent with the findings of Reyes-Gordillo et al. [28]. We found that the translocation of NF-κB p65 protein into nucleus and TNF-α and IL-1β mRNA expression were inhibited in rat pretreated oligonol, suggesting that oligonol acts, at least in part, by inhibition of NF-κB activity.

Beside proinflammatory cytokines, NF-κB regulates the expression of the inflammatory proteins COX-2 and iNOS. This study showed a significant increase of COX-2 and iNOS mRNA expression levels in the liver treated CCl4. These increases were attenuated by treatment with oligonol. In the study with HepG2 cells, the increased COX-2 protein levels in t-BHP-treated cells were also reduced by pretreatment of oligonol in a dose-dependent manner. These results suggest that oligonol exerts effects in suppressing inflammatory responses caused by CCl4 or t-BHP.

A series of upstream kinases including MAPKs and Akt are involved in a relay in transmitting stimuli-induced signals to the downstream transcription factors like NF-κB by regulating transcriptional activation of a variety of genes encoding COX-2, iNOS, TNF-α, and IL-1β. MAPKs mediate intracellular signaling associated with a variety of cellular activities including cell proliferation, differentiation, survival, death, and transformation [29]. The mammalian MAPK family consists of ERK, JNK, and p38. The MAPK pathways are activated by diverse extracellular and intracellular stimuli including cytokines and various cellular stressors such as oxidative stress caused ROS and endoplasmic reticulum stress. Activated MAPKs phosphorylate various substrate
Figure 7: Effects of oligonol on COX-2 and iNOS mRNA expression after CCl₄ administration. RT-PCR was performed to measure COX-2 and iNOS mRNA expression in the liver tissues. Values are mean ± SE of n = 6. ** p < 0.01 compared with the control group and # p < 0.05 and ## p < 0.01 compared with the CCl₄ group.

Figure 8: Effects of oligonol on CCl₄-induced NF-κB p65 activation. Western blotting was performed to detect nuclear and cytoplasmic localization of NF-κB p65 in the livers tissues. The relative level of NF-κB p65 in the nuclear and cytosol compared with β-actin and histon, respectively, and quantified by image analysis. Values are mean ± SE of n = 6. * p < 0.05 compared with the control group and # p < 0.05 compared with the CCl₄ group.
proteins including transcription factors like NF-κB. Our results also showed that CCl₄ exposure induced activation of MAPKs in rat liver, and oligonol inhibited CCl₄-induced JNK, ERK, and p38 phosphorylation. In addition, in order to activate NF-κB in response to specific stimuli, NF-κB needs to first be liberated from its inhibitory IκB partner [30]. On phosphorylation by IκB kinase (IKK), IκB is degraded by the proteasome and NF-κB is set free. IKK can be activated by Akt. In this study, phosphorylation of Akt was increased in CCl₄-intoxicated rats, while oligonol suppressed this Akt activation. This suggests that oligonol is involved with the Akt/NF-κB pathway.

5. Conclusion

The findings of the present study indicate that oligonol is highly effective in preventing CCl₄-induced acute liver damage, which is most likely mediated by its activity to suppress oxidative stress and lipid peroxidation as an antioxidant. It has capacity to inhibit NF-κB p65 activation and the expression of the proinflammatory cytokines, TNF-α and IL-1β, and proinflammatory proteins, such as COX-2 and iNOS. The underlying mechanisms for this NF-κB inactivation may be due to inhibition of the activation of upstream kinases including ERK, JNK, and p38 MAPKs as well as Akt. Our data
suggests that oligonol may be useful as a therapeutic agent for the suppression of hepatic inflammation.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

Acknowledgments

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIP) (no. 2009-0083538). The authors thank the Aging Tissue Bank (Busan, Korea) for supplying research materials.
