*Clostridium stercorarium* strain DSM 8532 is a thermophilic bacterium capable of efficiently degrading polysaccharides in plant biomass and converting the resulting sugars to ethanol and acetate. The complete genome sequence of 2.96 Mbp reveals a multitude of genes for hydrolytic enzymes and enables further study of the organism and its enzymes, and their exploitation for biotechnological processes.

Transfer of *Thermobacteroides leptospartum* and *Clostridium thermolacticum* as *Clostridium stercorarium* subsp. *leptospartum* subsp. *thermolacticum* subsp. nov., (Intergrated Microbial Genomes/Expert Review) system (17) and manually curated by using the Swiss-Prot, TREMBL, and InterPro databases (18). The genome harbors 3 rRNA operons and 48 tRNA genes, which were identified with RNAmmer and tRNAscan, respectively (19, 20). The genes for tRNA^sec^ and for selenocysteine incorporation are missing. We identified 10 CRISPR loci with 3 to 63 repeats and 3 gene clusters encoding Cas proteins, 2 of which contain cas8a1 and are classified as subtype I-A/Apern type (21). Approximately 82% of the 2,687 protein-coding genes (CDS) could be assigned to functions, and the remaining 474 CDS (18%) are hypothetical proteins (455 CDS) and pseudogenes (18 CDS). Blast analysis revealed that approximately 79% of the CDS could be allocated to the 21 functional clusters of orthologous groups (COGs), a percentage that is in the same range as described for other clostridia. The most abundant groups are replication, recombination, and repair (6.85%); amino acid transport and metabolism (8.13%); and carbohydrate transport and metabolism (12.13%). Compared to results for other clostridia, the number of CDS belonging to the last group is relatively high.

**Nucleotide sequence accession number.** The genome sequence of *Clostridium stercorarium* subsp. *stercorarium* DSM 8532 has been deposited in GenBank under accession number CP004044.
