Introduction

Patients undergoing allogeneic stem cell transplantation (allo-HCT) require profound immunosuppression is required to preserve graft function and prevent graft-versus host disease (GVHD), resulting in a high risk of infectious complications such as invasive fungal diseases (IFIs). Posaconazole is approved for primary antifungal prophylaxis alloHCT. However, posaconazole is associated with drug-drug interactions which may lead to relevant toxicities limiting it uses in hematological patients. Other triazoles, amphotericine B, and echinocandins can be used in patients at high risk of IFIs. However, there is less evidence supporting the efficacy of these drugs for the prevention of IFIs.

**Cases presentation**

**Case 1:** A 40-year-old female with ALK-positive anaplastic lymphoma received RIC alloHCT from a 10/10 HLA MRD after achieving third complete remission in February 2019. Disease relapse was diagnosed five months after alloHCT, and it was successfully treated with four cycles of brentuximab vedotin. Two donor lymphocyte infusions were administered as a consolidative approach. Overlapping severe chronic GVHD involving skin, oral mucosa, eyes and liver was diagnosed in April 2020. High dose prednisone, therapeutic tacrolimus, and extracorporeal photopheresis were started in combination with isavuconazole for antifungal prophylaxis. The patient presented clinical response to GVHD. No fungal infections, adverse events or drug–drug interactions with tacrolimus were documented. Isavuconazole prophylaxis was discontinued after 5 months, once prednisone was withdrawn.

**Case 2:** A 45-year-old male with acute myeloblastic leukemia in complete remission underwent a 10/10 HLA MRD, RIC alloHCT in February 2019. Severe ocular and lung cGVHD was diagnosed in November 2019 and treated with prednisone and sirolimus, followed by dasatinib. Severe COVID19 pulmonary infection was diagnosed April 2020, and it was resolved after hydroxychloroquine, a single dose of tocilizumab, and steroids. COVID19 disease triggered a flare of the cGVHD causing severe respiratory insufficiency in May 2020. Prednisone was increased to 2 mg/kg and sirolimus, and dasatinib were continued. Isavuconazole was started. Sirolimus dose has not required adjustment during the follow-up, and to date, the patient continues to be on isavuconazole prophylaxis. No fungal infections or adverse events have been documented.

**Case 3:** A 25-year-old female with Hodgkin lymphoma in partial remission after four lines of treatment underwent RIC alloHCT from a 10/10 HLA MRD in February 2019. GVHD prophylaxis was composed of PTCY-MMF and CsA. CsA was discontinued secondary to posterior reversible encephalopathy syndrome on day +18. Grade IV skin acute GVHD was diagnosed on March 2019. High-dose steroids and sirolimus were started, and primary antifungal prophylaxis with isavuconazole was added. Neither drug interactions nor fungal infections were documented during the 5 months that the patient was on isavuconazole prophylaxis. Complete response of the clinically relevant GVHD was achieved. Multiple infections and viral reactivations complicated the post-transplant phase leading into a poor graft function. The patient was admitted on July 2019 because of septic shock secondary to E. coli bloodstream infection. The course was complicated with a respiratory insufficiency due to alveolar hemorrhage and the patient deceased on August 2019.

**Case 4:** A 58-year-old female with diffuse large B-cell lymphoma in complete remission after three lines of treatment underwent RIC alloHCT from a haploidentical donor in July 2020. GVHD prophylaxis consisted of PTCY, MMF and tacrolimus. Acute cardiogenic pulmonary edema and severe kidney injury with an elevation of the creatinine levels up to 188 mcmol/L was diagnosed on day +10. GVHD prophylaxis was modified to methylprednisolone followed by sirolimus in monotherapy. Antifungal prophylaxis was modified to isavuconazole, and no breakthrough fungal infections, drug interactions, or adverse events were diagnosed. Sirolimus dose did required adjustment after starting isavuconazole prophylaxis. Primary anti-fungal prophylaxis with isavuconazole was discontinued at day +100 after haploHCT as per protocol.

**Case 5:** A 64-year-old female with Philadelphia-negative acute lymphoblastic leukemia underwent RIC alloHCT from a 10/10 HLA MRD after achieving a second complete remission on December 2019. Pulmonary IA was diagnosed two months before alloHCT and was successfully treated with voriconazole 200 mg/12 h. Secondary prophylaxis with voriconazole was started after alloHCT with the aim of being continued until the discontinuation of the immunosuppression (tacrolimus). Rising liver and cholestatic enzymes were documented since the early post-transplant phase with a significant worsening on April 2020. Voriconazole was switched to isavuconazole on May 2020 and a progressive normalization of liver function tests was documented. Tacrolimus dosage did not required adjustment. Isavuconazole was continued for 8 weeks and no toxicities or IA recurrences were diagnosed.

**Discussion**

In summary, we report a single-center experience using isavuconazole for broad-spectrum antifungal prophylaxis after alloHCT. After starting isavuconazole prophylaxis there was not any suspicion of invasive fungal disease, and breakthrough IFIs and IA reactivations were not documented. No adverse events were diagnosed. Antifungal prophylaxis is a challenging aspect of the post-alloHCT care. The strong inhibition of CYP3A4 enzyme mediated by posaconazole and voriconazole can increase plasma concentrations of immunosuppressant drugs requiring a close and universal monitoring of pharmacological levels. Micafungin and amphotericin B can be used as an alternative to minimize pharmacological interactions; however, these drugs are administered intravenously. Several aspects make isavuconazole a good candidate for antifungal prophylaxis in alloHCT, and its efficacy for IFIs prevention has been explored with promising results. Main studies supporting the effectiveness of isavuconazole used for antifungal prophylaxis on immunocompromised patients are summarized in Table 1. Although isavuconazole is a moderate CYP3A4 inhibitor and drug-drug interactions need to be taken into consideration, they seem to be modest in comparison with other triazoles. Our experience shows that tacrolimus and sirolimus dose did not had to be modified during the duration of isavuconazole prophylaxis. However, conclusions are limited by the reduced sample size. With some exceptions, plasmatic levels of isavuconazole do not need to be routinely monitored. In addition, it counts with an intravenous and oral disposition expanding the use of this drug for the impatient and outpatient management. Isavuconazole induces less hepatobiliary toxicity than other triazoles, conferring an advantage for the use of this newly triazole in alloHCT. The safety of isavuconazole administration in patients with renal impairment has also been investigated with positive results.

In summary, the use isavuconazole for prophylaxis against IFDs is not established. However, the reduced pharmacological...
