NUMERICAL METHODS FOR A DIFFUSIVE CLASS NONLOCAL OPERATORS

LOIC CAPPANERA, GABRIELA JARAMILLO, AND CORY WARD

Abstract. In this paper we develop a numerical scheme based on quadratures to approximate solutions of integro-differential equations involving convolution kernels, $\nu$, of diffusive type. In particular, we assume $\nu$ is symmetric and exponentially decaying at infinity. We consider problems posed in bounded domains and in $\mathbb{R}$. In the case of bounded domains with nonlocal Dirichlet boundary conditions, we show the convergence of the scheme for kernels that have positive tails, but that can take on negative values. When the equations are posed on all of $\mathbb{R}$, we show that our scheme converges for nonnegative kernels. Since nonlocal Neumann boundary conditions lead to an equivalent formulation as in the unbounded case, we show that these last results also apply to the Neumann problem.

Key words. nonlocal diffusion operator, integro-differential equations, finite difference method, numerical approximation, convergence analysis.

AMS subject classifications. 41A55 (approximate quadratures), 4505 (linear integral equations), 45J05 (integro-differential equation), 45J05 (integral operators), 65R20 (numerical methods for integral equations).

1. Introduction. In this paper we are interested in developing numerical algorithms for approximating nonlocal evolution processes of the form

\begin{equation}
\begin{aligned}
    u_t(x,t) = \int_{\mathbb{R}} (u(y,t) - u(x,t))\nu(x,y) \, dy + f(x), \\
    x \in \Omega \subset \mathbb{R},
\end{aligned}
\end{equation}

where $\nu(x,y) = \nu(|x-y|)$ is a symmetric, extended, and exponentially decaying function of diffusive type.

Integro-differential equations like the one above appear, for example, as model equations for diffusion processes that occur over fast time scales. They can be derived by first considering a reaction diffusion system, and then using a Green’s function to approximate the fast variable in terms of the slow variables. The result is a nonlocal equation (or system) involving a convolution kernel which describes a dispersion processes that lies somewhere between regular diffusion, as expressed by the Laplace operator, and anomalous diffusion modeled, for instance, using the Fractional Laplacian. More precisely, when viewed as probability density functions for a random walk, the kernels considered here have finite second moment. Generally, this implies that the process has a characteristic length scale, and one might be tempted to switch the convolution kernel for the Laplace operator with an appropriate diffusion constant. However, as has been shown (see for example [29, 30, 21, 5, 17]) this simplification misses the true character of the fast diffusion process and precludes one from finding interesting behavior, like for example chimera states [29].

Other examples of systems that can be described using equation (1.1) come from population dynamics [28, 26, 8], and oscillating chemical reactions [31, 29, 20]. Variations of the above integro-differential equation also appear in other physical systems where nonlocal effects are important. For instance, in [3] the authors explore a nonlocal continuum model for phase transitions, and in [6] a model for the evolution of

a particle system is presented. Extensions of the above equation in which the integral operator is nonlinear, are also typical of neural field models. In this case, the linearization about the homogenous steady state has the form of equation (1.1), see for example [4, 18, 7] and [9].

Although in most applications $\Omega$ represents a physical domain that is bounded, when the phenomenon of interest occurs at small spatial scales compared to the size of this domain, it is reasonable to pose the equation on all of $\mathbb{R}$. This is the case for example when showing existence of traveling waves in predator prey models [10], or existence of target patterns solutions in oscillating chemical reactions [24].

On the other hand, when both scales are comparable and $\Omega$ is considered to be a bounded subset of $\mathbb{R}$, boundary conditions need to be formulated carefully. Given that the model is now described by an integro-differential equation, it is not enough to prescribe the value of the solution or its derivatives at the boundary. Instead, boundary conditions take the form of volume constraints, see [12, 13]. Indeed, in various applications volume constraints can provide an equivalent notion to Dirichlet and Neumann boundary conditions that, moreover, is consistent with the assumptions made in deriving evolution equations of the form (1.1). See also the discussion in Section 2.

In both cases, bounded and unbounded $\Omega$, one is interested in validating and guiding the mathematical analysis using numerical simulations. Currently, one approach to approximate equation (1.1) is to use an exponential time difference scheme, [25]. This consists in picking a large domain, applying the Fourier transform to the spatial variable, and then using an RK4 method to advance the time steps while computing any nonlinearities in real space. One of the disadvantages of this approach is that the implied periodic boundary conditions are not always desired. Moreover, computations can become costly if one also needs a small spatial discretization to resolve small scale phenomena.

Alternatively, if the kernel $\nu(x,y)$ has as its Fourier symbol a fractional polynomial, then it is possible to precondition the equation with an appropriate differential operator and obtain as a result a PDE, see for example [27]. One can then proceed to solve the problem using finite differences, and impose local Dirichlet or Neumann boundary conditions. The main drawback from this approach is that the type of convolution kernels one can consider is restricted.

The goal of this paper is to propose a numerical method based on quadratures for computing steady states,

$$\int_{\mathbb{R}} (u(x,t) - u(y,t))\nu(|x-y|) \, dy = f(x), \quad x \in \Omega \subset \mathbb{R}. \quad (1.2)$$

which, in contrast to the methods mentioned above, accounts for nonlocal boundary conditions. In particular, we provide schemes for approximating solutions to (1.2) when

i) $\Omega \subset \mathbb{R}$ is bounded and we know the value of the solution in $\Omega^c$.

ii) $\Omega = \mathbb{R}$ and we assume the algebraic decay of the solution.

iii) $\Omega \subset \mathbb{R}$ is bounded and we know the algebraic decay of the solution and the nonlocal flux from $\Omega^c$ into $\Omega$.

Our scheme is adapted from [22], where the authors look at item i) in the particular case when $\nu(|x-y|)$ is the integral kernel associated with the Fractional Laplacian, $(-\Delta)^{\alpha/2}$, $0 < \alpha < 2$. Our main contribution is to extend this result and provide a proof of convergence for all three schemes in the case of kernels that satisfy Hypotheses 3.2 and 3.3, and that are therefore exponentially decaying, do not have compact support,
and that, in the case of problems with Dirichlet boundary conditions, are allowed to take negative values.

Notice that the properties exhibited by our kernels are in direct contrast to those considered in most of the literature pertaining to the numerical approximation of nonlocal equations. Indeed, most numerical schemes deal with either the integral form of the fractional Laplacian, [22, 2, 1, 14, 15] or with nonlocal operators involving kernels that are positive and compactly supported [16, 33, 13, 32, 11].

In addition, since the problems considered here are posed on the whole real line, there are additional difficulties not encountered when looking at bounded domains with, for example, Dirichlet boundary conditions, or at problems that involve positive kernels with compact support. Mainly the issue to be addressed is how to approximate the solution outside the computational domain.

On the other hand, from a theoretical point of view it is not immediately clear that solutions to problem (1.2) posed on all of $\mathbb{R}$ exist and are unique. Here we adapt previous results from [24] to show that the assumption of algebraic decay for solutions to equation (1.2) is justified provided the right hand side, $f$, also has a sufficient decay and satisfies some compatibility conditions (zero mean and zero first moment).

Our results are organized as follows. In Section 2 we derive equation (1.1) as a model for population dynamics using conservation of mass, and explain how nonlocal Dirichlet and Neumann boundary conditions can be naturally defined. In Section 3 we prove that the nonlocal problem (1.2) has a unique solution if the equation is posed on a particular class of weighted Sobolev spaces, and we also derive conditions on the right hand side, $f$, that guarantee existence of a unique solution. These results will then allow us to prove the convergence of our schemes. In Section 4 we adapt the methods from [22] to the problems i), ii) and iii). The convergence of the numerical schemes is established in Section 5. Finally, in Sections 6.1, 6.2, and 6.3 we provide examples for cases i), ii), and iii), respectively.

2. Nonlocal Flux, Gauss Theorem, and an Example.

2.1. Nonlocal Flux. To give an intuitive notion of what constitutes a nonlocal flux, we first recall the traditional definition of this term. In physical applications flux represents the rate of motion per unit area of a quantity $u$ (fluid, concentration, number of particles) across some boundary. Implicit in this definition is the assumption that the transport of this quantity happens at small scales. However, in certain applications transport can occur over long, as well as short, spatial scales. Consider for example an area of vegetation with seeds that can travel close to as well as far from their originating organisms thanks to wind currents. In this case flux is no longer proportional to a local quantity, like $u$ (transport equation) or the gradient of $u$ (diffusion equation), but instead should be expressed through a nonlocal operator.

We can make these ideas more precise by looking again at our vegetation example. For simplicity assume for now that we only have one organism at position $y$, whose seeds are entering a field $\Omega$. Suppose as well that we have a function $\phi(x, y, t)$ that tells us the proportion of seeds from position $y \notin \Omega$ that fall in location $x \in \Omega$ per unit time. Then the flow of seeds from $y$ into region $\Omega$ is given by the integral

$$\int_{\Omega} \phi(x, y, t) \, dx.$$
More generally, one can construct a function $\psi(x,y,t)$ such that

$$\int_{\Omega} \psi(x,y,t) \, dx,$$

represents a nonlocal flux density. Then, the expression

$$\int_{\Omega_1} \int_{\Omega_2} \psi(x,y,t) \, dx \, dy$$

gives us the net nonlocal flux from region $\Omega_1$ into region $\Omega_2$. If this expression is positive then indeed we have net flux from $\Omega_1$ into $\Omega_2$. On the other hand, if this quantity is negative, then the net flow occurs in the reverse direction.

For the above definition to be consistent with our intuition of how flux should behave, one imposes an action-reaction principle. Given two distinct domains $\Omega_1$, $\Omega_2$ we would like for the nonlocal flux from $\Omega_1$ into $\Omega_2$ to be equal in magnitude, but of opposite sign, as the the nonlocal flux from $\Omega_2$ into $\Omega_1$, i.e.

$$\int_{\Omega_1} \int_{\Omega_2} \psi(x,y,t) \, dx \, dy + \int_{\Omega_2} \int_{\Omega_1} \psi(y,x,t) \, dy \, dx = 0.$$ 

It is straightforward to check that this holds provided $\psi$ is antisymmetric in $x$ and $y$, that is $\psi(x,y,t) = -\psi(y,x,t)$. Notice that this condition also implies that there are no self interactions, meaning that

$$\int_{\Omega} \int_{\Omega} \psi(x,y,t) \, dx \, dy = 0.$$

2.2. Nonlocal Gauss’ Theorem. Given a bounded domain $\Omega$, Gauss’ Theorem relates the total flux across the boundary $\partial \Omega$, in terms of a volume integral over the domain, $\Omega$. More precisely, if $F$ represents a smooth vector field and $n$ the unit normal to $\Omega$, then

$$\int_{\Omega} \nabla \cdot F \, dV = \int_{\partial \Omega} F \cdot n \, dS.$$

In the nonlocal case, the action-reaction principle provides an analogue to Gauss’ Theorem since it relates the flux from $\Omega^c$ into $\Omega$ in terms of an integral over $\Omega$,

$$\int_{\Omega^c} \int_{\Omega} \psi(x,y,t) \, dx \, dy = \int_{\Omega} \int_{\Omega^c} -\psi(x,y,t) \, dx \, dy.$$

2.3. Example. To illustrate our point suppose we are interested in the evolution of a population that is able to move short as well as long distances. Let $u(x,t)$ denote the density of this population at time $t$ and location $x$, and let $\Omega \subset \mathbb{R}^n$ be a bounded domain. Then $m = \int_{\Omega} u(x,t) \, dx$ represents the total number of individuals in $\Omega$ at time $t$.

Assume as well that the fraction of the population that flows from $x$ to $y$ depends on the distance between these two points and is proportional to the density at point $x$. More precisely, at time $t$ the flow from $x \in \Omega$ to $y \in \Omega^c$ is given by the product $u(x,t) \nu(x,y)$, where we also assume that the kernel $\nu(x,y) = \nu(|x-y|)$ is symmetric and exponentially decaying. Then, the flow from the point $x \in \Omega$ to the domain $\Omega^c$ is given by the integral

$$\int_{\Omega^c} u(x,t) \nu(|x-y|) \, dy,$$

and the total flow out of $\Omega$ can be represented by the expression

$$\int_{\Omega} \int_{\Omega^c} u(x,t) \nu(|x-y|) \, dy \, dx.$$
Similarly, the flow from $\Omega^c$ into the point $x \in \Omega$ can be written as
\[
\int_{\Omega^c} u(y, t) \nu(|x - y|) \, dy
\]
so that the total flow into $\Omega$ is
\[
\int_{\Omega} \int_{\Omega^c} u(y, t) \nu(|x - y|) \, dy \, dx.
\]

Combining these two expressions we find that the net flow, $Q$, of the population in/out of the domain $\Omega$ is given by

\[
Q = -\int_{\Omega} \int_{\Omega^c} u(x, t) \nu(|x - y|) \, dy \, dx + \int_{\Omega} \int_{\Omega^c} u(y, t) \nu(|x - y|) \, dy \, dx
\]

\[
Q = \int_{\Omega} \int_{\Omega^c} -(u(x, t) - u(y, t)) \nu(|x - y|) \, dy \, dx.
\]

where the last line follows from the flow density function $\psi(x, y, t)$ being antisymmetric, and the fact that this rules out self-interactions.

By conservation of mass
\[
m_t = \int_{\Omega} u_t \, dx = \int_{\Omega^c} -(u(x, t) - u(y, t)) \nu(|x - y|) \, dy \, dx + \int_{\Omega} f \, dx,
\]

where $f(x)$ is a density specifying the net loss/gain of individuals at location $x$ that combines births and deaths. Since the domain $\Omega$ is arbitrary, the result is an evolution equation for the variable $u$,

\begin{equation}
(2.1) \quad u_t = -\mathcal{L} * u + f(x) \quad \text{for} \quad x \in \Omega
\end{equation}

where
\[
\mathcal{L} * u = \int_{\mathbb{R}^n} (u(x, t) - u(y, t)) \nu(|x - y|) \, dy.
\]

Now, because the flow is nonlocal, instead of boundary conditions across $\partial \Omega$, we need to impose conditions on $\Omega^c$:

- **Dirichlet**: One specifies the value of the function $u$ in $\Omega^c$
  \[
  u(x) = g(x) \quad \text{for} \quad x \in \Omega^c.
  \]

- **Neumann**: Since by the nonlocal Gauss' Theorem $\int_{\Omega^c} \int_{\mathbb{R}^n} -\psi(x, y, t) \, dy \, dx$ represents the net flow in/out of $\Omega^c$, then the following relation specifies a given and fixed flow density, $f_c(x)$, from $\Omega^c$ into the domain $\Omega$,
  \[
  \int_{\mathbb{R}^n} \psi(x, y, t) \, dy = f_c(x) \quad x \in \Omega^c.
  \]

- **Mixed**: Given $\Omega^c = \Omega_1^c \cup \Omega_2^c$
  \[
  u(x) = g(x) \quad \text{for} \quad x \in \Omega_1^c,
  \]
  \[
  \int_{\mathbb{R}^n} \psi(x, y, t) \, dy = f_c(x) \quad \text{for} \quad x \in \Omega_2^c.
  \]
In this paper we concentrate on the 1-dimensional case and propose numerical schemes to approximate the steady states of equation (1.1), with nonlocal Dirichlet boundary conditions

\[
\begin{align*}
(L) & \quad \mathcal{L} u = f \quad \text{for} \quad x \in \Omega, \\
& \quad u = g \quad \text{for} \quad x \in \Omega^c,
\end{align*}
\]

Neumann boundary conditions

\[
\begin{align*}
(N) & \quad \mathcal{L} u = f \quad \text{for} \quad x \in \Omega, \\
& \quad \mathcal{L} u = f_c \quad \text{for} \quad x \in \Omega^c,
\end{align*}
\]

and defined on the whole real line

\[
\begin{align*}
(R) & \quad \mathcal{L} u = f \quad \text{for} \quad x \in \mathbb{R}.
\end{align*}
\]

Then, the full evolution equation can be solved by incorporating a time stepping scheme such as an RK-4 method.

**Remark 2.1.** Notice that in the case when the flux is prescribed, the equations for the steady state take the form

\[
\mathcal{L} \ast u = \bar{f}(x) \quad x \in \mathbb{R},
\]

where

\[
\bar{f}(x) = \begin{cases} 
  f(x) & \text{for} \quad x \in \Omega, \\
  f_c(x) & \text{for} \quad x \in \Omega^c.
\end{cases}
\]

### 3. Weighted Spaces and Nonlocal Diffusive Operators

In this section we recall the results from [23] where it is shown that under certain assumptions on the kernel \(\nu(x, y)\), operators defined by equation (1.2) are Fredholm operators. These results rely on a special class of weighted Sobolev spaces, which we recall first before stating the assumptions on \(\nu(x, y)\) and \(f(x)\). Our goal for this section is to show that the equation,

\[
\mathcal{L} \ast u = f(x) \quad x \in \mathbb{R},
\]

is well defined.

#### 3.1. Notation and Weighted Sobolev Spaces

For \(s \in \mathbb{N} \cup \{0\}, \quad p \in (1, \infty)\), and \(\gamma \in \mathbb{R}\), we let \(M_s^{\gamma,p}(\mathbb{R})\) denote the space of locally summable, \(s\) times weakly differentiable functions \(u : \mathbb{R} \to \mathbb{R}\) endowed with the norm

\[
\|u\|_{M_s^{\gamma,p}(\mathbb{R})} = \sum_{j=0}^{s} \|\partial_j^s u\|_{L_p^{\gamma,s}(\mathbb{R})},
\]

where \(\|u\|_{L_p^\gamma(\mathbb{R})} = \|(1 + |x|^2)^{\gamma/2} u\|_{L_p(\mathbb{R})}\).

It is clear that for values of \(\gamma > 0\) these spaces impose a certain level of algebraic decay, whereas for values of \(\gamma < 0\) functions are allowed to grow algebraically. This definition also allows for the following embeddings: \(M_s^{\gamma,p}(\mathbb{R}) \subset M_s^{\lambda,p}(\mathbb{R})\) provided \(\gamma > \lambda\), and \(M_s^{\gamma,p}(\mathbb{R}) \subset M_k^{\lambda,p}(\mathbb{R})\) if \(s > k\).

Notice that we can extend the above definition to non integer values of \(s\) by interpolation and to negative values of \(s\) by duality. For values of \(p \in (1, \infty)\) these spaces are also reflexive so that \((M_s^{\gamma,p}(\mathbb{R}))^* = M_{-\gamma,q}(\mathbb{R})\), where \(p\) and \(q\) are conjugate.
exponents. The pairing between \( f \in L^p_s(\mathbb{R}) \) and an element in the dual space \( g \in L^2_{-\gamma}(\mathbb{R}) \) is given by the usual integral

\[
\langle f, g \rangle = \int_{\mathbb{R}} fg \, dx.
\]

In addition, if \( p = 2 \) then the spaces \( M^2_{\gamma}(\mathbb{R}) \) are Hilbert spaces with inner product

\[
\langle f, g \rangle = \sum_{j=0}^{\infty} \int_{\mathbb{R}} \partial^j_x f \partial^j_x g (1 + |x|^2)^{(j+\gamma)} \, dx.
\]

The following lemma describes the algebraic decay of functions belonging to \( M^1_{\gamma}(\mathbb{R}) \) for positive values of the parameter \( \gamma \).

**Lemma 3.1.** Given \( \gamma > 0 \), a function \( f \in M^1_{\gamma}(\mathbb{R}) \) satisfies \( |f(x)| \leq \|f'\|_{L^1_{\gamma,2}} |x|^{1/(\gamma+1)} \) as \( |x| \to \infty \).

**Proof.** Since \( \gamma > 0 \) we may write \( |f(x)| \leq \int_{-\infty}^{x} |f'(y)| (1+y^2)^{((\gamma+1)/2)} (1+y^2)^{-(\gamma+1)/2} \, dy \).

The result then follows from Hölder’s inequality. \( \square \)

**Notation:** In this paper we will also use the symbol \( W^s_{\gamma,p}(\mathbb{R}) \) to denote the space of locally summable, \( s \) times weakly differentiable functions that are bounded under the norm

\[
\|u\|_{W^s_{\gamma,p}(\mathbb{R})} = \sum_{j=0}^{\infty} \| (1 + |x|^2)^{\gamma/2} \partial^j_x u \|_{L^p(\mathbb{R})}.
\]

In the case when \( p = 2 \) we will also write \( H^s_{\gamma}(\mathbb{R}) = W^s_{\gamma,2}(\mathbb{R}) \). Furthermore, we will use \( \langle , \rangle \) to denote the pairing between an element in \( M^k_{\gamma}(\mathbb{R}) \) and its dual \( M^{-k}_{-\gamma}(\mathbb{R}) \), and \( ( , ) \) to denote the inner product on the Hilbert spaces \( M^k_{\gamma}(\mathbb{R}) \).

### 3.2. Nonlocal Diffusive Operators on the Real Line

In this section we let \( L(k) \) denote the Fourier symbol of the operator \( \mathcal{L} \). Our main assumptions are

**Hypothesis 3.2.** The domain of the multiplication operator, \( L(k) \), can be extended to a strip in the complex plane, \( \Omega = \mathbb{R} \times (-ik_0, ik_0) \) for some sufficiently small and positive \( k_0 \in \mathbb{R} \), and on this domain the operator is uniformly bounded and analytic. Moreover, there is a constant \( k_m \in \mathbb{R} \) such that the operator \( L(k) \) is invertible with uniform bounds for \( |\text{Re}k| > k_m \).

Note that because \( L(k) \) is analytic its zeros are isolated. We can therefore assume that:

**Hypothesis 3.3.** The multiplication operator \( L(k) \) has a zero, \( k^* \), of multiplicity \( m \) which we assume is at the origin. Therefore, the symbol \( L(k) \) admits the following Taylor expansion near the origin.

\[
L(k) = \alpha(-ik)^m + O(k^{m+1}), \quad \text{for} \quad k \to 0 \quad \alpha = \pm 1.
\]

**Remark 3.4.** In this paper we will consider the particular case when \( m = 2 \), so that this last assumption specifies that the operator behaves very much like the Laplacian for small wavenumbers, giving its diffusive character.

**Remark 3.5.** Given that \( \nu(x, y) = \delta(x-y) - \mathcal{L} \), the analyticity of the symbol \( L(k) \) implies that \( \nu(x,y) \) is exponentially localized. Similarly, because \( L(k) \) has a zero of multiplicity \( m \) at the origin, then the first \( m-1 \) moments of the kernel \( \delta(x-y) - \nu(x,y) \) must be zero, while the \( m \)-th moment must be bounded.
As was shown in [23], under the above hypotheses the convolution operator \( \mathcal{L} \) is a Fredholm operator in an appropriate weighted space. This means in particular that the operator has a closed range and a finite dimensional kernel and cokernel. Here we define the cokernel of an operator as the kernel of its adjoint.

The results presented in [23] apply to more general operators defined over \( L^2(\mathbb{R}, Y) \), where \( Y \) is a separable Hilbert space, and that commute with the action of translations on \( L^2(\mathbb{R}, Y) \). Here we consider the case when \( Y = \mathbb{R} \) and summarize the results from [23] in this next theorem.

**Theorem 1.** Let \( p \in (1, \infty) \) with \( q \) its conjugate exponent, and let \( \gamma \in \mathbb{R} \) be such that \( \gamma + m + 1/p \notin \{1, \cdots, m\} \). Suppose as well that the convolution operator \( \mathcal{L} : M_{\gamma}^{m,p}(\mathbb{R}) \to W_{\gamma+m}^{\ell,p}(\mathbb{R}) \) satisfies Hypotheses 3.2 and 3.3. Then, with appropriate value of the integer \( \ell \), the operator is Fredholm and

- for \( \gamma < 1 - m - 1/p \) it is surjective with kernel spanned by \( \mathbb{P}_m \);
- for \( \gamma > -1 + 1/q \) it is injective with cokernel spanned by \( \mathbb{P}_m \);
- for \( j - 1 - m + 1/q < \gamma < j + 1 - m - 1/p \), where \( j \in \mathbb{N}, 1 \leq j < m \), its kernel is spanned by \( \mathbb{P}_{m-j} \) and its cokernel is spanned by \( \mathbb{P}_j \).

Here \( \mathbb{P}_m \) is the \( m \)-dimensional space of all polynomials with degree less than \( m \).

The above results follows from Lemma 3.6 and Proposition 3.7, which show that under the above hypotheses the convolution operators considered here can be written as the composition of an invertible operator and a Fredholm operator. These results can also be found in [23].

**Lemma 3.6.** Let the multiplication operator \( L(k) \) satisfy Hypothesis 3.2-3.3. Then \( L(k) \) admits the following decomposition:

\[
L(k) = M_L(k) L_{NF}(k) = L_{NF}(k) M_R(k),
\]

where \( L_{NF}(k) = (-ik)^m/(1 \pm ik)^4 \), while \( M_L/R(\xi) \) and their inverses are analytic and uniformly bounded on \( \Omega \).

**Proposition 3.7.** Let \( m \) and \( \ell \) be non negative integers, and \( p \in (1, \infty) \) with \( q \) its conjugate exponent. Then the operator

\[
(1 \pm \partial_x)^{-\ell} \partial_x^m : M_\gamma^{m,p}(\mathbb{R}) \to W_{\gamma+m}^{\ell,p}(\mathbb{R})
\]

is Fredholm for \( \gamma + m + 1/p \notin \{1, \cdots, m\} \). In particular,

- for \( \gamma < 1 - m - 1/p \) it is surjective with kernel spanned by \( \mathbb{P}_m \);
- for \( \gamma > -1 + 1/q \) it is injective with cokernel spanned by \( \mathbb{P}_m \);
- for \( j - 1 - m + 1/q < \gamma < j + 1 - m - 1/p \), where \( j \in \mathbb{N}, 1 \leq j < m \), its kernel is spanned by \( \mathbb{P}_{m-j} \) and its cokernel is spanned by \( \mathbb{P}_j \).

For \( \gamma + m + 1/p \in 1, \cdots, m \) the operator does not have a closed range. Here \( \mathbb{P}_m \) is the \( m \)-dimensional space of all polynomials with degree less than \( m \).

Heuristically, the main reason why operators of the form \( (1 \pm \partial_x)^{-\ell} \partial_x^m \) are not Fredholm in regular Sobolev spaces is because they have a zero eigenvalue embedded in their essential spectrum. In particular, this means that one can use the corresponding eigenfunction to construct Weyl sequences and consequently show that the operator does not have closed range.

For example, consider the one dimensional Laplacian \( \partial_x^2 : H^2(\mathbb{R}) \to L^2(\mathbb{R}) \). Its nullspace is spanned by \( \{1, x\} \), and although these functions are not in \( H^2(\mathbb{R}) \), one can use them to construct Weyl sequences. Let \( u_n = \chi_n(x)/\|\chi_n(x)\|_{H^2} \), where \( \chi_n(x) \) is a smooth function that is equal to one on the interval \([-n, n]\) and that it is equal...
to zero on $\mathbb{R}\setminus (-n + 1, (n + 1)]$. This sequence satisfies $\|u_n\|_{H^2} = 1$ and $\|\partial_x^2 u_n\|_{L^2} \to 0$, showing that operator does not have a closed range.

The reason for using the spaces $M^s_p(\mathbb{R})$ is that by picking positive values of $\gamma$, and thus imposing algebraic decay, one can remove the limit of the above Weyl sequences from the domain of these operators. On the other hand, by picking negative values of $\gamma$ and allowing algebraic growth, these sequences will now converge to an element in the domain.

In this paper we will restrict ourselves to functions $f(x)$ in weighted Sobolev spaces, $L^2_p(\mathbb{R})$, that impose a high degree of algebraic decay. As a result our convolution operators will have a two dimensional cokernel spanned by at most $\{1, x\}$ (since we are assuming $m = 2$).

The goal for us is to reformulate the problem so that we deal with an invertible operator. This means that we will look at the following system

$$L \ast u + a_1 L \ast P_1(x) + a_2 L \ast P_2(x) = f(x) \quad x \in \mathbb{R},$$

where $f(x) \in L^2_p(\mathbb{R})$ is given, $u(x)$ and $a_i \in \mathbb{R}$, with $i \in \{1, 2\}$, represent the variables we want to solve for, and $L \ast P_i(x) \in C^\infty(\mathbb{R})$, are functions that span the cokernel of our operator. In particular we require

$$\langle L \ast P_1, 1 \rangle = \int_{\mathbb{R}} L \ast P_1(x) \, dx = 1 \quad \langle L \ast P_1, x \rangle = \int_{\mathbb{R}} L \ast P_1(x) \cdot x \, dx = 0$$

$$\langle L \ast P_2, 1 \rangle = \int_{\mathbb{R}} L \ast P_1(x) \, dx = 0 \quad \langle L \ast P_2, x \rangle = \int_{\mathbb{R}} L \ast P_2(x) \cdot x \, dx = 1$$

For example, one may pick $P_1(x) = (1/2) \log(\cosh(x))$ and $P_2(x) = \partial_x P_1(x) = (1/2) \tanh(x)$.

The above discussion leads to the following proposition.

**Proposition 3.8.** Given $\gamma > -1 + 1/p$, the convolution operator $L$ with Fourier symbol $L(k) = M_L(k)(ik)^2/(1 + k^2)$ and defined as

$$L^\prime: M^2_p(\mathbb{R}) \times \mathbb{R} \times \mathbb{R} \to W^{2,p}_2(\mathbb{R})$$

$$(u, a_1, a_2) \mapsto L \ast (u + a_1 P_1 + a_2 P_2)$$

is invertible, and therefore well defined.

We also have the following corollary, which gives conditions on the right hand side of equation (3.1) that guarantee existence of solutions. This result is a consequence of the previous proposition and Lemma 3.1.

**Corollary 3.9.** Let $s \in \mathbb{Z} \cup [2, \infty)$, and $p \in (1, \infty)$ with $q$ its conjugate exponent. Consider the convolution operator $L$, with Fourier symbol $L(k) = M_L(k)(ik)^2/(1 + k^2)$, and defined as

$$L^\prime: M^s_p(\mathbb{R}) \to W^{s,p}_{2+2}(\mathbb{R})$$

$$(u, \ast \ast) \mapsto L \ast u.$$ 

Suppose $\gamma > -1 + 1/q$, then the equation $L \ast u = f$ has a unique solution, with $|u(x)| \leq C|x|^{s-1-1/p-(\gamma+1)}$ for large $|x|$, provided the right hand side $f(x) \in W^{s,p}_{2+2}(\mathbb{R})$ satisfies

$$\langle f, 1 \rangle = 0 \quad \text{and} \quad \langle f, x \rangle = 0.$$ 

**Remark 3.10.** Notice that by Lemma 3.1, if the function $f \in W^{2,p}_{2+2}(\mathbb{R})$, then for large $|x|$ we have that $|f(x)| \leq \|f\|_{L^{s+2}_{p+2}} |x|^{s/p-(\gamma+3)}$, where $p$ and $q$ are conjugate exponents.
Remark 3.11. If in addition to Hypotheses 3.2 and 3.3, the kernel \( \nu(x) \in L^2(\mathbb{R}) \), and the equation (3.1) is posed on a bounded domain, then
\[
\mathcal{L} * u = u(x) - \int_{\mathbb{R}} \nu(|x-y|)u(y) \, dy = u(x) - \int_{\Omega} \nu(|x-y|)u(y) \, dy,
\]
defines an operator \( \mathcal{L} : L^2(\Omega) \to L^2(\Omega) \) which is a compact perturbation of the identity. This follows since the integral in the above expression corresponds to a Hilbert-Schmidt operator. As a result, problem (DP) has a unique solution.

3.3. Nonlocal Diffusive Operators on a Lattice. The above results can be extended to operators \( \mathcal{L} \) defined on lattices. The following discussion follows again from the results presented in [23], which we summarize here for completeness.

We first define the analogue of the spaces \( L^2(\mathbb{R}), M^{2,s}(\mathbb{R}), \) and \( H^s(\mathbb{R}) \) in the obvious way and denote them by \( \ell^2(\mathbb{Z}), m_{2,s}^2(\mathbb{Z}), h_s^2(\mathbb{Z}) \), respectively. As above we use \( \langle, \rangle \) to denote the pairing between dual elements, and we let \( u = \{u_j\}_{j \in \mathbb{Z}} \).

In the case of lattices, the Fourier Transform is given by
\[
\mathcal{F}_d : \ell^2(\mathbb{Z}) \to L^2(\mathbb{T}_1) \quad u = \{u_j\}_{j \in \mathbb{Z}} \quad \mapsto \hat{u}(\sigma) = \sum_{j \in \mathbb{Z}} u_j e^{-2\pi j \sigma}
\]
where \( \mathbb{T}_1 = \mathbb{R}/\mathbb{Z} \) is the unit circle. We can also define discrete derivatives for elements in \( \ell^2(\mathbb{Z}) \),
\[
\delta_+\{u_j\}_{j \in \mathbb{Z}} = \{u_{j+1} - u_j\}_{j \in \mathbb{Z}} \quad \delta_-\{u_j\}_{j \in \mathbb{Z}} = \{u_j - u_{j-1}\}_{j \in \mathbb{Z}} \quad \delta = -i(\delta_+ + \delta_-)/2
\]
with their corresponding Fourier symbols,
\[
D_+ (\sigma) = e^{2\pi i \sigma} - 1, \quad D_- (\sigma) = 1 - e^{-2\pi i \sigma}, \quad D(\sigma) = \sin(2\pi \sigma).
\]

As was the case for operators defined on \( L^2(\mathbb{R}) \), the Fourier Transform of general convolution operators, \( L(\sigma) \), is a multiplication symbol defined on the space \( L^2(\mathbb{T}_1) \):
\[
\hat{\mathcal{L}} : D(\hat{\mathcal{L}}) \subset L^2(\mathbb{T}_1) \to L^2(\mathbb{T}_1) \quad u(\sigma) \quad \mapsto \quad L(\sigma)u(\sigma)
\]

Here, we make the following assumptions on the Fourier symbol \( L(\sigma) \), of our discrete convolution operators \( \mathcal{L} \).

Hypothesis 3.12. The symbol \( L(\sigma) \) is analytic, uniformly bounded, and 1-periodic in a strip \( \Omega_1 = \mathbb{R} \times (i\sigma_1, i\sigma_1) \) for some \( \sigma_1 > 0 \). Moreover, when restricted to \( \sigma \in [-1/2, 1/2] \) the symbol \( L(\sigma) \) is invertible except at \( \sigma = 0 \), where it has a zero of multiplicity \( m \).

As was the case in the real line, the operator \( \mathcal{L} \) can be decomposed into an invertible operator \( \mathcal{M}_I(\sigma) \) and a Fredholm operator with Fourier symbol \( (e^{2\pi i \sigma} - 1)^m[1 + iC \sin((2\pi \sigma))]^{-1} \), which formally corresponds to \( \delta_+^m(1 + \delta_-)^{-1} \). This leads to the following proposition.

Proposition 3.13. For \( \gamma \notin \{1/2, 3/2, \ldots, m-1/2\} \), and appropriate value of the integer \( l \), the operator \( \mathcal{L} : m_2^2(\mathbb{Z}) \to h_{2m}^2(\mathbb{Z}) \) satisfying Hypothesis 3.12 is Fredholm. Moreover, letting \( \eta^h = \{\eta^h\}_{\eta \in \mathbb{Z}} \), we have that
- for \( \gamma > -1/2 \) the operator is injective with cokernel

\[
\text{Coker} = \text{span}\{\eta^\beta \mid \beta = 0, 1, \ldots, m-1\}
\]
• for $\gamma < 1/2 - m$ the operator is surjective with kernel
  \[ \text{Ker} = \text{span}\{\eta^\beta | \beta = 0, 1, \ldots, m - 1\} \]

• for $j - 1/2 - m < \gamma < j - m + 1/2$, with $j \in \mathbb{Z}$, $1 \leq j < m$, the operator has kernel
  \[ \text{Ker} = \text{span}\{\eta^\beta | \beta = 0, 1, \ldots, m - j - 1\} \]

and cokernel
  \[ \text{Coker} = \text{span}\{\eta^\beta | \beta = 0, 1, \ldots, j - 1\}. \]

On the other hand, the operator does not have closed range when $\gamma \in \{1/2, 3/2, \ldots, m - 1/2\}$.

From the above result we obtain the next corollary, which we will use in the proof of convergence for the numerical schemes. In particular, the following result gives us information about the decay rate of solutions to the discrete convolution problem defined over $\ell^2(\mathbb{Z})$

\[ L \ast u = f. \]

**Corollary 3.14.** Consider the discrete convolution operator $L$, with Fourier symbol $(e^{2\pi i \sigma} - 1)^2[1 + (2i \sin(2\pi \sigma))^2]^{-1}$, and defined as

\[ L : m^{2,2}_2(\mathbb{Z}) \rightarrow h^{2,2}_2(\mathbb{Z}) \]

Suppose $\gamma > -1/2$, then the equation $L \ast u = f$ has a unique solution, with $|u_j| < C|\nu(y)|$ for large $|y|$, provided the right hand side $f \in h^2(\mathbb{Z})$ satisfies

\[ \langle f, 1 \rangle = 0 \quad \text{and} \quad \langle f, \eta \rangle = 0 \]

**4. A Numerical Method for nonlocal diffusive operators.** In this section, we extend the discretization scheme presented in Huang and Oberman’s paper [22] so it is valid for problems with more general kernels defined on the whole real line. In particular, the method presented here applies to equations of the form

\[ L \ast u(x) = \int_{\mathbb{R}} (u(x) - u(x - y)) \nu(y) \, dy = f(x) \quad x \in \mathbb{R} \]

where $\nu(y)$ is an exponentially localized kernel, so that the Fourier symbol $L(k)$ satisfies Hypotheses 3.2 and 3.3 with $m = 2$. In terms of the moments of $\nu(y)$, these assumptions lead to

\[ \int_{\mathbb{R}} \nu(y) \, dy = 1 \quad \text{and} \quad \int_{\mathbb{R}} \nu(y) y \, dy = 0. \]

Additionally, in order to bound the local truncation error in the numerical schemes, we also make the following assumptions

\[ \int_{\mathbb{R}} \nu(y) y^2 \, dy < \infty \quad \text{and} \quad \int_{\mathbb{R}} \nu(y) y^4 \, dy < \infty, \quad u \in C^4(\mathbb{R}). \]

In Remark 2.1, we noted that equation (4.1) also encompasses problems posed on a bounded domain with nonlocal Neumann boundary conditions. Thus, the results presented in this section also apply to this type of situations. Similarly, the result presented here also apply to Dirichlet boundary problems where the equation (4.1) is considered on a bounded domain $\Omega \subset \mathbb{R}$. 

4.1. Discretization of the Operator. As a first step, we set up a numerical grid defined by \( x_i = ih, \ i \in \mathbb{Z} \) and \( h > 0 \). We then split Eq. (4.1) into a (possibly) singular part and a tail:

\[
\mathcal{L} \ast u(x) = \int_{-h}^{h} [u(x) - u(x - y)] \nu(y) \, dy + \int_{|y| > h} [u(x) - u(x - y)] \nu(y) \, dy.
\]

We denote the first and second integral by \( \mathcal{L}_S \ast u(x) \) and \( \mathcal{L}_T \ast u(x) \), respectively.

4.1.1. Discretization of the Singular Integral. We first rewrite the singular integral, considering it as a Cauchy P.V.:

\[
\mathcal{L}_S \ast u(x) = \int_{-h}^{h} [u(x) - u(x - y)] \nu(y) \, dy
\]

where \( \nu \) is chosen appropriately to ensure that the equality holds.

Assuming \( u \in C^4 \), we can use Taylor’s Theorem and expand \( u(x - y), u(x + y) \) to obtain that the above integral is

\[
-u''(x) \int_{0}^{h} y^2 \nu(y) \, dy - \frac{u^{(4)}(\xi_1)}{12} \int_{0}^{h} y^4 \nu(y) \, dy,
\]

where \( \xi_1 \in (x - h, x + h) \) is chosen appropriately to ensure that the equality holds. We can also rewrite \( u''(x) \), using a Taylor expansion, to get its second order finite difference formula:

\[
-\left[ \frac{u(x + h) - 2u(x) + u(x - h)}{h^2} + \frac{u^{(4)}(\xi_2)}{12} \right] \int_{0}^{h} y^2 \nu(y) \, dy - \frac{u^{(4)}(\xi_1)}{12} \int_{0}^{h} y^4 \nu(y) \, dy.
\]

Simplifying this result, we have

\[
\mathcal{L}_S \ast u(x) = -\left[ u(x + h) - 2u(x) + u(x - h) \right] f_1(h) - \frac{u^{(4)}(\xi_2)}{12} f_2(h) - \frac{u^{(4)}(\xi_1)}{12} f_3(h)
\]

where

\[
f_1(h) = \frac{1}{h^2} \int_{0}^{h} y^2 \nu(y) \, dy, \quad f_2(h) = h^2 \int_{0}^{h} y^2 \nu(y) \, dy, \quad f_3(h) = \int_{0}^{h} y^4 \nu(y) \, dy.
\]

For a specific grid point \( x_i \), we can rewrite the above formula as follows:

\[
\mathcal{L}_S \ast u(x_i) = \left[ u(x_i) - u(x_{i-1}) \right] f_1(h) + \left[ u(x_i) - u(x_{i+1}) \right] f_1(h) - \frac{u^{(4)}(\xi_2)}{12} f_2(h) - \frac{u^{(4)}(\xi_1)}{12} f_3(h).
\]
4.1.2. Discretization of the Tail Integral. Let $T(x)$ be the hat function

$$T(x) := \begin{cases} 1 - \frac{|x|}{h} & \text{if } |x| \leq h, \\ 0 & \text{otherwise}. \end{cases}$$

Then we can interpolate any function $f(x)$ on all of $\mathbb{R}$ as follows:

$$Pf(y) := \sum_{j=-\infty}^{\infty} f(x_j)T(y-x_j).$$

Note that this is just piecewise polynomial interpolation, where we’ve chosen the interpolating polynomials to be the linear (Lagrange) polynomials on their given domain $[x_i, x_{i+1}]$.

Letting $f(y) = u(x_i) - u(x_i - y)$ and plugging its interpolation into the tail integral we get

$$L_T * u(x_i) = \int_{|y| \geq h} f(y)\nu(y) \, dy$$

$$\approx \int_{|y| \geq h} Pf(y)\nu(y) \, dy$$

$$= \sum_{j=-\infty}^{\infty} \left[ (u(x_i) - u(x_i - x_j)) \int_{|y| \geq h} T(y-x_j)\nu(y) \, dy \right].$$

Because the hat function $T$ is zero almost everywhere, the latter integral is actually defined on finite interval and, as we will show later, it can be computed easily. Finally, because this is a polynomial interpolation, it can be shown that

$$L_T * u(x_i) := \int_{|y| \geq h} Pf(y)\nu(y) \, dy + O \left( h^2 \int_{h}^{\infty} |\nu(y)| \, dy \right).$$

4.1.3. Discretization of the Nonlocal Operator. Let

$$f_1(h) = \frac{1}{h^2} \int_{0}^{h} y^2\nu(y) \, dy, \quad f_3(h) = \int_{0}^{h} y^4\nu(y) \, dy,$$

$$f_2(h) = h^2 \int_{0}^{h} y^2\nu(y) \, dy, \quad f_4(h) = h^2 \int_{h}^{\infty} |\nu(y)| \, dy,$$

then using the above results, we can write

$$L * u(x_i) = L_S * u(x_i) + L_T * u(x_i)$$

$$= \sum_{j=-\infty}^{\infty} \left[ (u(x_i) - u(x_i - x_j))w_j \right] + O \left( f_2(h) \right) + O \left( f_3(h) \right) + O \left( f_4(h) \right),$$
where

\[
\begin{align*}
  w_j &= \begin{cases} 
    0 & \text{if } j = 0, \\
    f_1(h) + \int_{|y| \leq L} T(y-x_j)\nu(y) \, dy & \text{if } j = \pm 1, \\
    \int_{|y| \geq L} T(y-x_j)\nu(y) \, dy & \text{otherwise.}
  \end{cases}
\end{align*}
\]

(4.6)

Note that whenever \( j = 0 \), we have that \( u(x_i) - u(x_i - x_j) = 0 \) and hence we can define \( w_0 \) arbitrarily.

**Remark 4.1.** From equation (4.5) we can conclude that the order of the scheme presented in this section is given by

\[
\min \left\{ O(f_2(h)) + O(f_3(h)) + O(f_4(h)) \right\}.
\]

**4.2. Numerical Methods on a Finite Lattice.** Having found a discretization of the nonlocal operator that is also valid on the whole real line, we now focus on to its practical application. Namely, while the scheme approximates the nonlocal equations for any \( x \in \Omega \), where \( \Omega \) can be a bounded or unbounded subset of \( \mathbb{R} \), it still requires the calculation of an infinite number of weights, \( w_j \). In this section, we discuss how to modify the scheme such that only a finite number of weights need to be calculated as well as a few nontrivial integrals.

First, let \( M \) be some even number such \( L = \frac{M}{2}h \) and let \( L_W = 2L = Mh \). Define \( x_j = jh \) for \(-M \leq j \leq M\). Now, unlike in the previous section, we want to split the nonlocal operator as

\[
\mathcal{L} \ast u(x_i) = \int_{-h}^{h} \left[ u(x_i) - u(x_i - y) \right]\nu(y) \, dy + \int_{|y| \leq |L_W|} \left[ u(x_i) - u(x_i - y) \right]\nu(y) \, dy
\]

\[
+ u(x_i) \int_{|y| \leq L_W} \nu(y) \, dy - \int_{|y| \geq L_W} u(x_i - y)\nu(y) \, dy.
\]

Call these integrals (Ia), (Ib), (II), and (III) respectively. Note that integral (III) depends on the specific point \( x_i \) chosen.

Due to the local nature of the hat functions, we can repeat all of the arguments of Section 4.1 to write

\[
(Ia) + (Ib) = \sum_{j=-M}^{M} \left[ u(x_i) - u(x_i - x_j) \right] w_j
\]

\[
+ O(f_2(h)) + O(f_3(h)) + O(f_4(h))
\]

where

\[
\begin{align*}
  w_j &= \begin{cases} 
    0 & \text{if } j = 0, \\
    f_1(h) + \int_{|y| \leq L_W} T(y-x_j)\nu(y) \, dy & \text{if } j = \pm 1, \\
    \int_{|y| \geq L_W} T(y-x_j)\nu(y) \, dy & \text{if } 1 < |j| \leq M,
  \end{cases}
\end{align*}
\]

with the functions \( f_k(h) \) defined in (4.4). Note also that the weights \( w_j \) are still even here as well.
Integral (II) doesn’t depend of \( u(x) \) and can, in principle, be calculated analytically. Thus, for simplicity we define the constant \( A \) as

\[
A = \int_{|y| \geq L_W} \nu(y) \, dy.
\]

Lastly, integral (III) can also be calculated analytically depending on the specific problem under consideration. This step is described in the following.

### 4.3. Dirichlet Problem

We begin here by considering the Dirichlet problem

\[
\begin{aligned}
\mathcal{L} \ast u(x) &= f(x), \quad x \in (-L, L), \\
\quad u(x) &= g(x), \quad x \in (-L, L)^c.
\end{aligned}
\]

Note that \( L_W \) is the smallest number such that \( u(x_i - y) = g(x_i - y) \) for all \( |y| \geq L_W \) and all \(- \frac{M}{2} + 1 \leq i \leq \frac{M}{2} - 1\). Hence, defining \( B_i = (III) \) to highlight it’s dependence on \( i \), we have

\[
B_i = \int_{|y| \geq L_W} g(x_i - y) \nu(y) \, dy.
\]

Since \( \nu \) and \( g \) are given functions, the integral \( B_i \) can be calculated analytically. Dropping the big oh terms, our numerical scheme for the Dirichlet problem is given by

\[
\sum_{j=-M}^{M} \left( [u_i - u_{i-j}] w_j \right) + Au_i - B_i = f(x_i),
\]

for \(- \frac{M}{2} + 1 \leq i \leq \frac{M}{2} - 1\). Note that \( u_{\pm \frac{M}{2}} = g(x_{\pm \frac{M}{2}}) \) and so the boundary points, \( i = \pm \frac{M}{2} \), do not need to be solved for.

### 4.4. Whole Real Line Problem

In this section we consider the problem posed on the whole real line

\[
\mathcal{L} \ast u(x) = f(x), \quad x \in \mathbb{R}.
\]

Since \( \nu(x) \) and \( f(x) \) are given explicitly it may be possible in some cases to discern the asymptotic decay rate of the solution \( u(x) \). For example, if \( u(x) \) decays exponentially to zero then it should be possible to ignore the integral (III) by choosing \( L \) sufficiently large. This approximation is essentially the Dirichlet problem previously considered where we take \( g(x) = 0 \) (on a sufficiently large domain).

On the other-hand, if the solution \( u(x) \) decays too slowly (e.g. algebraically) to zero then ignoring the integral (III) could lead to large errors (or require extremely large domain sizes). To get around this issue, using corollaries 3.9-3.14, we know the approximate asymptotic decay rate of \( u(x) \) i.e. \( u(x) \sim g(x) \). Then to get a good approximation of the integral (III), we may assume

\[
u(x) \approx \begin{cases} \end{cases} u(L) \frac{g(x)}{g(L)}, \quad x \geq L, \\
u(-L) \frac{g(x)}{g(-L)}, \quad x \leq -L.
\]

Essentially this just assumes the decay rate is a good approximation of the solution outside the interval \([-L, L] \).
The advantage of this formulation, compared to the Dirichlet problem, is that we only assume the decay of the solution to be known. It allows us to use smaller values of \( L \) to get a given order of accuracy compared to the Dirichlet problem which assumes that the solution \( u(x) \) vanished for large values of \( x \). Thus, the Dirichlet method is either adequate for problem with exponentially decaying solution or requires large value of \( L \) when the solution decays algebraically.

Thus the integral (III) can be approximated as

\[
(\text{III}) = \int_{|y| \geq L} u(x_i - y) \nu(y) \, dy
\]

\[
\approx \frac{u(L)}{g(L)} \int_{|y| \geq L} g(x_i - y) \nu(y) \, dy
\]

\[
\approx \frac{u(-L)}{g(-L)} \int_{-\infty}^{-L} g(x_i - y) \nu(y) \, dy + \frac{u(L)}{g(L)} \int_{L}^{\infty} g(x_i - y) \nu(y) \, dy
\]

\[
= u(-L) B_i^1 + u(L) B_i^2
\]

\[
= u_{-\frac{M}{2}} B_i^1 + u_{\frac{M}{2}} B_i^2,
\]

where

\[
B_i^1 = \int_{-\infty}^{-L} \frac{g(x_i - y)}{g(-L)} \nu(y) \, dy, \quad B_i^2 = \int_{L}^{\infty} \frac{g(x_i - y)}{g(L)} \nu(y) \, dy.
\]

We now see that the integrals \( B_i^1 \) and \( B_i^2 \) can be calculated analytically. This is slightly different from the Dirichlet problem we considered before as \( u(-L) \) and \( u(L) \) are now unknowns and must be solved for in the numerical scheme itself. With that said, we can write the complete scheme as

\[
\sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j + Au_i - u_{-\frac{M}{2}} B_i^1 - u_{\frac{M}{2}} B_i^2 = f(x_i)
\]

for all \(-\frac{M}{2} \leq i \leq \frac{M}{2}\) and it’s understood that whenever \( |i-j| > \frac{M}{2} \) we replace \( u_{i,j} \) with the approximation (4.12). Notice that the range of allowed \( i \) values has increased to account for the fact that \( u_{-\frac{M}{2}} \) and \( u_{\frac{M}{2}} \) are now unknowns.

### 4.5. Neumann Problem

Here we consider the Neumann problem

\[
\begin{align*}
\Delta u(x) &= f(x), & x \in (-L, L), \\
\frac{\partial u}{\partial n}(x) &= f_n(x), & x \in (-L, L)^c,
\end{align*}
\]

where the solution is assumed to decay algebraically, meaning that the equation (4.12) is satisfied for a given \( g \) and \( L > \tilde{L} > 0 \). Recall that this is equivalent to solving the whole real line problem

\[
\Delta u(x) = \bar{f}(x), \quad x \in \mathbb{R}
\]

where

\[
\bar{f}(x) = \begin{cases} f(x), & x \in (-\tilde{L}, \tilde{L}), \\
\tilde{f}(x), & x \in (-\tilde{L}, L)^c.
\end{cases}
\]
Hence, since we’ve already developed a numerical method which solves the problem on the whole real line, we can apply it verbatim to also solve Neumann problems.

5. Proofs of Convergence. In this section we established the convergence of the numerical schemes introduced in the previous section, meaning the schemes approximating the solution of problems of the type (DP), (RP) and (NP).

5.1. Dirichlet. Consider again the Dirichlet scheme

\[ \sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j + Au_i - B_i = f(x_i) \]

for \(-\frac{M}{2} + 1 \leq i \leq \frac{M}{2} - 1\). In this section we will write this system in matrix form and then derive bounds on the eigenvalues of the corresponding matrix. Together with the local truncation error derived earlier, this will show the scheme converges.

In addition to assumptions (4.2) and (4.3), we will also assume in this section that \( \nu(y) \) is an arbitrary \( L^1(\mathbb{R}) \) function, taking positive or negative values, such that for all sufficiently large values of \( L \) we have that the tails are strictly positive:

\[ \int_{|y| > 2L} \nu(y) \, dy > 0. \]

This hypothesis will be sufficient to show that the scheme is stable.

5.1.1. Stability. To write the scheme in matrix form, we focus first on the summation and, for ease of presentation, we let \( u_k := u(x_k) \). We then have

\[ \sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j = u_i \sum_{j=-M}^{M} w_j - \sum_{j=-M}^{M} u_{i-j} w_j \]

\[ = u_i \sum_{j=-M}^{M} w_j - \sum_{|i-j| \leq \frac{M}{2} - 1} u_{i-j} w_j - \sum_{|i-j| > \frac{M}{2} - 1} u_{i-j} w_j. \]

Note that in the last sum of the second line we have \( u_{i-j} = g_{i-j} \). Keeping in mind that \( i \) is a fixed constant here, it reads

\[ \sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j = u_i \sum_{j=-M}^{M} w_j - \sum_{j=i-\frac{M}{2} + 1}^{i+\frac{M}{2} - 1} u_{i-j} w_j - \sum_{j=i+\frac{M}{2} - 1}^{i-\frac{M}{2} + 1} g_{i-j} w_j. \]

Renaming the above quantities as follows

\[ c^1 = \sum_{j=-M}^{M} w_j, \quad c^2_i = \sum_{j=-M}^{i-M} g_{i-j} w_j, \quad c^3_i = \sum_{j=i+\frac{M}{2}}^{i+\frac{M}{2} - 1} g_{i-j} w_j, \]

we get

\[ \sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j = u_i c^1 - c^2_i - \sum_{j=i+\frac{M}{2} + 1}^{i+\frac{M}{2} - 1} u_{i-j} w_j \]

\[ = u_i c^1 - c^2_i - c^3_i - \sum_{k=i+\frac{M}{2} + 1}^{\frac{M}{2} - 1} u_k w_{i-k}. \]
The last equality is obtained by the change of variables \( k = i - j \). Letting \( \hat{u} \) denote the vector

\[
\begin{bmatrix}
  u_{-\frac{M}{2}} \\
  \vdots \\
  u_{\frac{M}{2} - 1}
\end{bmatrix},
\]

we can rewrite the above equation in matrix form as

\[
c^1 \hat{u} - c^2 - c^3 - \hat{w} \hat{u},
\]

where \( c^2, c^3 \) are vectorized versions of \( c^2_i, c^3_i \) and \( \hat{w} \) is the matrix given by

\[
\begin{bmatrix}
  w_0 & w_{-1} & \cdots & w_{-M+2} \\
  w_1 & w_0 & \cdots & w_{-M+3} \\
  \vdots & \vdots & \ddots & \vdots \\
  w_{M-2} & w_{M-3} & \cdots & w_0
\end{bmatrix}.
\]

Note that since \( w_{-j} = w_j \) the matrix is symmetric and in fact Toeplitz. We can then write the numerical scheme for the Dirichlet problem as

\[
c^1 \hat{u} - c^2 - c^3 - \hat{w} \hat{u} + A \hat{u} - B = \hat{f}
\]

or, equivalently,

\[(c^1 I - \hat{w} + AI) \hat{u} = \hat{f} + c^2 + c^3 + B.\]

Letting \( N = c^1 I - \hat{w} + AI \), we note that \( N \) is symmetric and Toeplitz as well.

Following the work of [19], we now derive bounds on the eigenvalues of \( N \). Define the symmetric, Toeplitz matrix \( S \) as the matrix whose first row is given by

\[
\begin{bmatrix}
  0 & -w_{M-2} & \cdots & -w_{M-3} & -w_2 & -w_1 \\
  -w_{M-2} & 0 & \cdots & -w_2 & -w_1 \\
  \vdots & \vdots & \ddots & \vdots \\
  -w_1 & -w_2 & \cdots & 0
\end{bmatrix}
\]

Now define the block matrix \( C \) as

\[
C = \begin{bmatrix} N & S \\ S & N \end{bmatrix},
\]

and note that not only is \( C \) a symmetric, Toeplitz matrix but it is also circulant. Since it’s circulant, the eigenvalues are given explicitly by

\[
\lambda_j = \sum_{k=1}^{2M-2} C_{1k} z_j^{k-1} = (c^1 + A) - w_1 z_j - w_2 z_j^2 - \cdots - w_{M-2} z_j^{M-2} - w_{M-2} z_j^M - w_{M-3} z_j^{M+1} - \cdots - w_1 z_j^{2M-3},
\]

where \( z_j = \exp(i \frac{2 \pi j}{2M-2}) \) and \( 0 \leq j \leq 2M - 3 \).
Let $\mu_1$ and $\mu_{M-1}$ denote the smallest and largest eigenvalues of $N$, respectively. Then using the main result of [19] we can bound the eigenvalues of $N$ by the eigenvalues of $C$. Specifically, we have

\[
\begin{align*}
\left( \min_{j \text{ even}} \lambda_j \right) + \left( \min_{j \text{ odd}} \lambda_j \right) & \leq 2\mu_1, \\
\left( \max_{j \text{ even}} \lambda_j \right) + \left( \max_{j \text{ odd}} \lambda_j \right) & \geq 2\mu_{M-1}.
\end{align*}
\]

We then see that if we can derive a lower bound for all the $\lambda_j$ then this will also be a lower bound for $\mu_1$. Noting that $z_j^{2M-2} = 1$, we can write

\[
\begin{align*}
\lambda_j &= (c^1 + A) - w_1 z_j - w_2 z_j^2 - \cdots - w_{M-2} z_j^{M-2} \\
&\quad + z_j^{2M-2}(-w_{M-2} z_j^{-M+2} - w_{M-3} z_j^{-M+3} - \cdots - w_1 z_j^{-1}) \\
&= c^1 + A - \sum_{k=2-M}^{M-2} w_k z_j^k \\
&= \sum_{k=-M}^{M} w_k + A - \sum_{k=2-M}^{M-2} w_k z_j^k.
\end{align*}
\]

If we now use the fact that $w_j = \nu(hj)h + O(h^2)$ and $h = \frac{2L}{M}$ then we can rewrite the above as

\[
\begin{align*}
\lambda_j &= \int_{-2L}^{2L} \nu(x) \, dx + A - \int_{-2L}^{2L} \nu(x) e^{j\pi x} \, dx + O(h) \\
&= 1 - \int_{-2L}^{2L} \nu(x) e^{j\pi x} \, dx + O(h) \\
&= 1 - \int_{-2L}^{2L} \nu(x) \cos\left(\frac{j\pi}{2L} x\right) \, dx + O(h) \\
&\to 1 - \int_{-2L}^{2L} \nu(x) \cos\left(\frac{j\pi}{2L} x\right) \, dx \quad \text{as} \quad h \to 0.
\end{align*}
\]

Define $A_j = 1 - \int_{-2L}^{2L} \nu(x) \cos\left(\frac{j\pi}{2L} x\right) \, dx$ and note that since the $\lambda_j$ get arbitrarily close to the $A_j$, it’s sufficient to show that $A_j$ is bounded away from zero for all $j$. In the special case that $j = 0$, we see that $A_0 = A > 0$.

For $j \geq 1$, denote the symbol of $L$ as $\hat{L}$ so that we can write

\[
\begin{align*}
\Lambda_j &= \hat{L} \left(\frac{j\pi}{2L}\right) + \int_{|x| \geq 2L} \nu(x) \cos\left(\frac{j\pi}{2L} x\right) \, dx \\
&\geq \hat{L} \left(\frac{j\pi}{2L}\right) - \int_{|x| \geq 2L} \nu(x) \, dx \\
&\geq \hat{L} \left(\frac{j\pi}{2L}\right) - 2e^{-\eta L} \\
&= M \left(\frac{j\pi}{2L}\right) \frac{(\frac{j\pi}{2L})^2}{1 + (\frac{j\pi}{2L})^2} - 2e^{-\eta L} \\
&\geq c_M \frac{(j\pi)^2}{(2L)^2 + (j\pi)^2} - 2e^{-\eta L}
\end{align*}
\]
where in the second line we’ve used that the tails are positive, in the third line we’ve used that \(\nu(x)\) is exponentially localized for large values of \(L\), in the fourth line we use the lemma 3.6, in the fifth line that \(M\) is bounded below by the positive constant \(c_M\), and in the sixth line that it’s always possible to choose \(L\) large enough such that \(c_M \frac{(\nu(x))^2}{(2L)^2 + (\nu(x))^2} - 2e^{-\eta L} \) is positive for all \(j \geq 1\). To finish, note that \(c_M \frac{(\nu(x))^2}{(2L)^2 + (\nu(x))^2} - 2e^{-\eta L} \) is an increasing function of \(j\) so that \(\Lambda_j\) is bounded below by \(c_M \frac{(\nu(x))^2}{(2L)^2 + (\nu(x))^2} - 2e^{-\eta L} \) for all \(j \geq 1\). Defining \(\Lambda_{\min} = \min\{A, c_M \frac{(\nu(x))^2}{(2L)^2 + (\nu(x))^2} - 2e^{-\eta L}\}\), this immediately gives that \(\mu_1 \geq \Lambda_{\min} > 0\) and implies the scheme is stable in the (grid) 2-norm.

**5.1.2. Consistency.** To get a precise bound on the local truncation error, note that since \(\nu \in L^1(\mathbb{R})\), we can apply Holder’s Inequality to the integrals in Eqs. (4.4). Doing so yields

\[
|f_2(h)| \leq h^4|\nu|_{L^1(\mathbb{R})}, \quad |f_3(h)| \leq h^4|\nu|_{L^1(\mathbb{R})}, \quad |f_4(h)| \leq h^2|\nu|_{L^1(\mathbb{R})},
\]

which shows that the local truncation error is at least \(O(h^2)\).

**5.1.3. Convergence.** Changing notation slightly, let \(U(x)\) be the solution of the problem (DP), given by Eq. (4.8), \(\hat{u}\) be the solution of the corresponding discrete scheme above, and define \(E^h = U(x_i) - \hat{u}_i\) for all \(-\frac{M}{2} + 1 \leq i \leq \frac{M}{2} - 1\). Denoting the local truncation error by LTE, we have

\[
NE^h = NU - N\hat{u}
\]

\[= NU + c^2 + c^3 + B - N\hat{u} - c^2 - c^3 - B = \hat{f} + LTE - \hat{f} = LTE.
\]

Inverting the matrix \(N\) and applying the properties of grid norms gives

\[
\|E^h\|_2 \leq \|N^{-1}\|_2 \|LTE\|_2 \leq \frac{1}{\Lambda_{\min}} \|LTE\|_2 \leq \frac{1}{\Lambda_{\min}} \|LTE\|_{\infty}
\]

Since \(LTE = O(h^2)\) and \(\Lambda_{\min}\) doesn’t depend on \(h\), we can take the limit as \(h \to 0\) on both sides to conclude that \(E^h \to 0\), so that the scheme converges.

**5.2. Whole Real Line Problem.** Consider again the scheme for the whole real line

\[
\sum_{j=-M}^{M} \left[ (u_i - u_{i-j})w_j \right] + Au_i - u_{-\frac{M}{2}} B_1^i - u_{\frac{M}{2}} B_2^i = f(x_i),
\]

for \(-\frac{M}{2} \leq i \leq \frac{M}{2}\). As the resulting matrix equation isn’t symmetric, we will proceed in a different way than the previous subsection to show that the scheme converges. To do this, in addition to Eqs. (4.2) and (4.3), we will assume in this section that \(\nu(y)\) is
a nonnegative $L^1(\mathbb{R})$ function such that for all sufficiently large values of $L$ we have that the tails are strictly positive:

\[
\int_{|y|>2L} \nu(y) \, dy > 0.
\]

This contrasts with the Dirichlet problem in that we do not allow the kernel to take possibly negative values.

Because of Corollary 3.9, we will assume that $f$ has been chosen such that the solution $u(x)$ of the (UP) problem satisfies $|u(x)| \leq \frac{C}{|x|^q}$ for all sufficiently large $x$ and some constants $C, q > 0$. We will then define the decay function as $g(x) := \frac{1}{|x|^q}$.

5.2.1. Stability. As before, we first focus on the matrix form of the discrete convolution term. We have

\[
\sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j = u_i \sum_{j=-M}^{M} w_j - \sum_{j=-M}^{M} u_{i-j} w_j
\]

\[
= u_i \sum_{j=-M}^{M} w_j - \sum_{|i-j| \leq \frac{M}{2}} u_{i-j} w_j - \sum_{|i-j| > \frac{M}{2}} u_{i-j} w_j
\]

\[
= u_i \sum_{j=-M}^{M} w_j - \sum_{j=0}^{i-\frac{M}{2}} u_{i-j} w_j - \sum_{j=-\frac{M}{2}}^{i-1} u_{i-j} w_j - \sum_{j=i+\frac{M}{2}+1}^{M} u_{i-j} w_j
\]

\[
= u_i \sum_{j=-M}^{M} w_j - \sum_{j=0}^{i-\frac{M}{2}} u_{i-j} w_j - \sum_{j=0}^{i-\frac{M}{2}} u_{i-j} w_j - \sum_{j=i+\frac{M}{2}+1}^{M} g_{i-j} w_j
\]

\[- u \frac{|L|^q}{q} \sum_{j=i+\frac{M}{2}+1}^{M} g_{i-j} w_j.
\]

Renaming the above quantities as follows

\[c_1 = \sum_{j=-M}^{M} w_j, \quad c_2^i = |L|^q \sum_{j=-M}^{i-\frac{M}{2}} g_{i-j} w_j, \quad c_3^q = |L|^q \sum_{j=0}^{M} g_{i-j} w_j,
\]

we get

\[\sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j = u_i c_1 - u_{-\frac{M}{2}} c_2^i - u_{\frac{M}{2}} c_3^i - \sum_{j=i-\frac{M}{2}}^{i+\frac{M}{2}} u_{i-j} w_j
\]

\[= u_i c_1 - u_{-\frac{M}{2}} c_2^i - u_{\frac{M}{2}} c_3^i - \sum_{k=-\frac{M}{2}}^{M} u_k w_{i-k}.
\]

The last equality is obtained by the change of variables $k = i - j$. Letting $\hat{u}$ denote the vector

\[
\begin{bmatrix}
  u_{-\frac{M}{2}} \\
  \vdots \\
  u_{\frac{M}{2}}
\end{bmatrix},
\]

we have

\[
\sum_{j=-M}^{M} \left( u_i - u_{i-j} \right) w_j = u_i c_1 - u_{-\frac{M}{2}} c_2^i - u_{\frac{M}{2}} c_3^i - \sum_{k=-\frac{M}{2}}^{M} u_k w_{i-k}.
\]
we can rewrite the above equation in matrix form as
\[ c^1 \hat{u} - u_{-M} c^2 - u_M c^3 - \hat{w} \hat{u} \]
\[ = (c^1 I - [c^2 0 \ldots 0 c^3] - \hat{w}) \hat{u}, \]
where \( \hat{w} \) is the matrix given by
\[
\begin{bmatrix}
  w_0 & w_{-1} & \ldots & w_{-M} \\
  w_1 & w_0 & \ldots & w_{-M} \\
  \vdots & \vdots & \ddots & \vdots \\
  w_M & w_{M-1} & \ldots & w_0
\end{bmatrix},
\]
c^2, c^3 are just vectorized versions of \( c^2_i, c^3_i \), and \([c^2 0 \ldots 0 c^3]\) has enough zero vectors to make the multiplication well-defined. We can then write the numerical scheme for the whole real line problem as
\[ (c^1 I + AI - [(c^2 + B^1) 0 \ldots 0 (c^3 + B^2)] - \hat{w}) \hat{u} = \hat{f} \]
which we note is neither symmetric nor Toeplitz like the Dirichlet case.

Defining \( N := c^1 I + AI - [(c^2 + B^1) 0 \ldots 0 (c^3 + B^2)] - \hat{w} \) and \( Z := I - N \), we now want to show that the \( L^\infty \) norm of \( Z \) is strictly less than one for all values of \( h \). We will then able to bound the \( L^\infty \) norm of \( N^{-1} \) in terms of the norm of \( Z \) via the corresponding Neumann series
\[ N^{-1} = \sum_{n=0}^{\infty} Z^n. \]
Further, since
\[ \| Z \|_\infty = \max_{0 \leq k \leq M} \sum_{j=0}^{M} |Z_{kj}| \]
it’s enough to show that the \( L^1 \) norm of each row is strictly less than one.

For simplicity, we first derive three inequalities which will be needed. To begin, note that
\[ A + c^1 = \int_{|y| \geq L} \nu(y) \, dy + \sum_{j=-M}^{M} w_j \]
\[ = \int_{|y| \geq L} \nu(y) \, dy + \sum_{j=-M}^{M} \int_{h \leq |y| \leq L} T(y - x_j) \nu(y) \, dy + 2f_1(h) \]
\[ = \int_{|y| \geq L} \nu(y) \, dy + \int_{h \leq |y| \leq L} \left( \sum_{j=-M}^{M} T(y - x_j) \right) \nu(y) \, dy + 2f_1(h) \]
\[ \leq \int_{|y| \geq L} \nu(y) \, dy + 2f_1(h) \leq 1, \]
where the last line is given by using that \( f_1(h) \leq \int_0^h \nu(y) \, dy \). Also, since \( |L|^g(y) \leq 1 \) for all \( |y| \geq L \) it follows that
\[ c^2_i \leq \sum_{j=-M}^{i-M-1} w_j, \quad c^3_i \leq \sum_{j=i+M+1}^{M} w_j \]
and, by using that the \( w_j \) are even, that
\[
\sum_{j=-k}^{M-k} w_j + c_2 \frac{2}{3} + k + c_3 \frac{3}{2} + k \leq c^1.
\]

Finally, define \( P_k(L) := \int_{|y| \geq Lw} (1 - |L|^q g(x, \frac{k}{2} + y)) \nu(y) \, dy \) and note that
\[
P_k(L) = \int_{|y| \geq Lw} (1 - |L|^q g(x, \frac{k}{2} + y)) \nu(y) \, dy
\]
\[
= \int_{|y| \geq Lw} (1 - \frac{|L|^q}{|x - \frac{k}{2} + y|^q}) \nu(y) \, dy
\]
\[
\geq \int_{|y| \geq 2Lw} (1 - \frac{|L|^q}{|x - \frac{k}{2} + y|^q}) \nu(y) \, dy
\]
\[
\geq \int_{|y| \geq 2Lw} (1 - \frac{|L|^q}{3|L|^q}) \nu(y) \, dy
\]
\[
= \left(1 - \frac{1}{3^q}\right) \int_{|y| \geq 2Lw} \nu(y) \, dy.
\]

Defining \( \Lambda_{\min}(L) := \left(1 - \frac{1}{3^q}\right) \int_{|y| \geq 2Lw} \nu(y) \, dy \), we note that \( \Lambda_{\min} \) is strictly positive and independent of \( h \). For reference, we list the three inequalities here as
\begin{align}
(5.3) & \quad c^1 + A \leq 1 \\
(5.4) & \quad \sum_{j=-k}^{M-k} w_j + c_2 \frac{2}{3} + k + c_3 \frac{3}{2} + k \leq c^1 \\
(5.5) & \quad P_k \geq \Lambda_{\min}.
\end{align}

Returning to the the \( Z \) matrix, we have for the first row that
\[
0 \leq \sum_{j=0}^{M} |Z_{0j}| = |1 - c^1 - A + c_2 \frac{2}{3} + B_1 \frac{1}{4} | + \sum_{j=1}^{M-1} |w_j| + |c_3 \frac{3}{2} + B_2 \frac{2}{3} + w_M|
\]
\[
\leq |1 - c^1 - A + c_2 \frac{2}{3} + B_1 \frac{1}{4} | + \sum_{j=1}^{M-1} |w_j| + |c_3 \frac{3}{2} + B_2 \frac{2}{3} + w_M|
\]
\[
= 1 - c^1 - A + c_2 \frac{2}{3} + B_1 \frac{1}{4} + \sum_{j=0}^{M} w_j + c_3 \frac{3}{2} + B_2 \frac{2}{3} + w_M
\]
\[
\leq 1 - A + B_1 \frac{1}{4} + B_2 \frac{2}{3}
\]
\[
= 1 - \int_{|y| \geq Lw} (1 - |L|^q g(x, \frac{k}{2} - y)) \nu(y) \, dy
\]
\[
= 1 - P_0
\]
\[
\leq 1 - \Lambda_{\min},
\]
where in the second line we used triangle inequality, in third we used inequality (5.3), in the fourth inequality (5.4), and in the last line inequality (5.5). Similarly, for the last row of the \( Z \) matrix we have
\[
0 \leq \sum_{j=0}^{M} |Z_{Mj}| = |c_2 \frac{2}{3} + B_1 \frac{1}{4} + w_M| + \sum_{j=1}^{M-1} |w_j| + |1 - c^1 - A + c_3 \frac{3}{2} + B_2 \frac{2}{3}|
\]
\[ \leq c_{2/M}^2 + B_M^1 + \sum_{j=0}^M w_j + 1 - c^1 - A + c_{M+1}^3 + B_M^2 \]
\[ \leq 1 - A + B_M^1 + B_M^2 \]
\[ = 1 - \int_{|y|\leq L_M} (1 - |L|^q g(x_M - y))\nu(y) \, dy \]
\[ = 1 - P_M \]
\[ \leq 1 - \Lambda_{\min}, \]

where the inequalities (5.3), (5.4), and (5.5) were used in the same way as before. By applying the same argument, we have for any row in between the first and last
\[ 0 \leq \sum_{j=0}^M |Z_{kj}| \]
\[ = |c_{-M+k}^2 + B_{-M+k}^1 + w_{-k}| + \sum_{j=-k}^{M-k-1} |w_j| + |1 - c^1 - A| + |c_{M+k}^3 + B_M^2 + w_{M-k}| \]
\[ \leq c_{-M+k}^2 + B_{-M+k}^1 + \sum_{j=-k}^{M-k} w_j + 1 - c^1 - A + c_{M+k}^3 + B_M^2 \]
\[ \leq 1 - A + B_{-M+k}^1 + B_M^2 + k \]
\[ = 1 - P_k \]
\[ \leq 1 - \Lambda_{\min}. \]

Since the same bound applies to each of the sums, we must have that
\[ \|Z\|_\infty \leq 1 - \Lambda_{\min} < 1. \]

We then have stability of the \( N \) matrix since
\[ \|N^{-1}\|_\infty = \|(I - Z)^{-1}\|_\infty \]
\[ = \left\| \sum_{n=0}^{\infty} Z^n \right\|_\infty \]
\[ \leq \sum_{n=0}^{\infty} \|Z\|_\infty^n \]
\[ \leq \sum_{n=0}^{\infty} (1 - \Lambda_{\min})^n \]
\[ = \frac{1}{\Lambda_{\min}}. \]

5.2.2. Consistency. The above argument establishes the numerical method is stable. We now need to bound the local truncation error in order to get consistency. To this end, we’d like to show that
\[ \int_{\mathbb{R}} (u(x_i) - u(x_i - y))\nu(y) \, dy \]
\[ = \sum_{j=-M}^M (u_i - u_{i-j})w_j + Au_i - u_{-M}B_1^1 - u_MB_1^2 \]
\[ + O(h^2, |L|^q), \]
where we’ve placed a tilde on the second term in the sum to remind the reader that if \( |i - j| > \frac{M}{2} \) then \( \tilde{u}_{i,j} = u(\pm L)|L|^q g_{i,j} \).

We’ll do this in four steps. First, decompose the integral on the LHS into four pieces, corresponding to each of the first four terms on the RHS respectively:

\[
\int_{-2L}^{2L} (u(x_i) - u(x_i - y)) \nu(y) \, dy + u(x_i) \int_{|y| \geq 2L} \nu(y) \, dy
- \int_{-\infty}^{-2L} u(x_i - y) \nu(y) \, dy - \int_{2L}^{\infty} u(x_i - y) \nu(y) \, dy.
\]

Second, note that if \( x \in [-L, L] \) and \( y \in (-2L, 2L)^c \) then

\[
|u(x - y) - \frac{u(\pm L)}{g(\pm L)} g(x - y)| \leq |u(x - y)| + |u(\pm L)\frac{g(x - y)}{g(\pm L)}|
\leq \frac{C}{|x - y|^q} + \frac{C}{|L|^q} \frac{|L|^q}{|x - y|^q}
\leq \frac{2C}{|x - y|^q}
\leq \frac{2C}{|L|^q}.
\]

Next, by using the previous inequality we get

\[
\left| \int_{|y| \geq 2L} u(x_i - y) \nu(y) \, dy - u \frac{B^1}{2} \right|
= \left| \int_{|y| \geq 2L} u(x_i - y) \nu(y) \, dy - \int_{|y| \geq 2L} \frac{u(L)}{g(L)} g(x_i - y) \nu(y) \, dy \right|
\leq \frac{2C}{|L|^q} \int_{y \geq 2L} \nu(y) \, dy,
\]

and something similar for the corresponding pair. If we now note that \( u(x_i) \int_{|y| \geq 2L} \nu(y) \, dy = Au_i \), then we have the preliminary bound

\[
u(x_i) \int_{|y| \geq 2L} \nu(y) \, dy - \int_{-2L}^{-\infty} u(x_i - y) \nu(y) \, dy - \int_{2L}^{\infty} u(x_i - y) \nu(y) \, dy
= Au_i - u \frac{B^1}{2} - \frac{B^2}{2} + O(|L|^{-q}).
\]

Finally, consider the last remaining integral \( \int_{-2L}^{2L} (u(x_i) - u(x_i - y)) \nu(y) \, dy \). We have

\[
\left| \int_{-2L}^{2L} (u(x_i) - u(x_i - y)) \nu(y) \, dy - \sum_{j=-M}^{M} \left( [u_i - \tilde{u}_{i,j}] w_j \right) \right|
\leq \left| \int_{-2L}^{2L} (u(x_i) - u(x_i - y)) \nu(y) \, dy - \sum_{j=-M}^{M} \left( [u_i - u_{i,j}] w_j \right) \right|
+ \left| \sum_{j=-M}^{M} \left( [u_i - u_{i,j}] w_j \right) - \sum_{j=-M}^{M} \left( [u_i - \tilde{u}_{i,j}] w_j \right) \right|.
\]
\[
= \int_{-2L}^{2L} (u(x) - u(x - y)) \nu(y) \, dy - \sum_{j=-M}^{M} \left[ (u_i - u_{i-j}) w_j \right] \\
+ \sum_{j=-M}^{M} \left[ (u_i - \tilde{u}_{i-j}) w_j \right].
\]

With regards to the last line, note that for fixed \(L\) we’ve already shown in the Dirichlet problem section that the first term is \(O(h^2)\); as long as we take \(h \to 0\) before changing \(L\), this first term will be identically zero. By using our inequality above, the second term can be bounded as
\[
\left| \sum_{j=-M}^{M} \left[ (u_i - \tilde{u}_{i-j}) w_j \right] \right| \leq \frac{2C}{|L|^q} \int_{-2L}^{2L} \nu(y) \, dy,
\]
which we note is independent of \(h\).

Collecting results, this shows Eq. (5.6) holds true and the scheme is consistent for all sufficiently large \(L\). Further, for all sufficiently large \(L\), as \(h \to 0\) we have that the pointwise error term is bounded above by
\[
\|E^h\|_\infty \leq \frac{2C}{|L|^q} \int_{|y| \geq 2L} \nu(y) \, dy + \frac{2C}{|L|^q} \int_{-2L}^{2L} \nu(y) \, dy
\]
\[
= \frac{2C}{|L|^q}.
\]

5.2.3. Convergence. Let \(U(x)\) be the solution of the problem (UP), given by Eq. (4.11), \(\tilde{u}\) be the solution of the corresponding discrete scheme above, and define
\[
E^h_i = U(x) - \tilde{u}_i \quad \text{for all} \quad -\frac{M}{2} \leq i \leq \frac{M}{2}.
\]
Denoting the local truncation error by LTE, we have
\[
NE^h = NU - N\tilde{u} = \hat{f} + LTE - \hat{f} = LTE.
\]

Inverting the matrix \(N\) and applying the properties of grid norms gives
\[
\|E^h\|_\infty \leq \|N^{-1}\|_\infty \|LTE\|_\infty \\
\leq \frac{1}{\Lambda_{\min}} \|LTE\|_\infty.
\]

Since \(LTE = O(h^2,|L|^{-q})\) and \(\Lambda_{\min}\) doesn’t depend on \(h\), we can take the limit as \(h \to 0\) on both sides to conclude that
\[
\lim_{h \to 0} \|E^h\|_\infty \leq \frac{1}{\Lambda_{\min}} \frac{2C}{|L|^q}.
\]
Notice however that because the bound for the smallest eigenvalue of matrix \(N\), \(\Lambda_{\min}\), decays exponentially with \(L\), the convergence of our scheme as \(L\) goes to infinity is not established. Nonetheless, our numerical examples show that for fixed \(L\) the algorithm does converge at order \(O(h^2)\), which is to be expected when \(h^2 > L^{-q}\). We suspect that because the right hand side, \(f\), decays algebraically and satisfies the compatibility conditions \(\langle f, 1 \rangle = \langle f, x \rangle = 0\), just like in the analytical setting (see Section 3), the solution avoids small wavenumbers, allowing for the convergence of the scheme for large values of \(L\).
6. Numerical illustrations. Here we consider a series of examples to illustrate the usefulness of our numerical schemes.

6.1. Dirichlet Problem. Consider the Dirichlet problem

\begin{equation}
\begin{cases}
L u(x) = f(x), & x \in (-L, L), \\
u(x) = \text{sech}(x), & x \in (-L, L)^c,
\end{cases}
\end{equation}

with

\[ \nu(y) = \frac{1}{2} e^{-|y|} \text{, } f(x) = \text{sech}(x) - \frac{1}{2} e^{-x} \log(1 + e^{2x}) - \frac{1}{2} e^x \log(1 + e^{2x}) + xe^x. \]

Then by direct calculation, we have that

\[ f_1(h) = \frac{1}{2} h^{-2} \left[ 2 - e^{-h}(h^2 + 2h + 2) \right] = \frac{h}{6} + O(h^2), \]
\[ f_2(h) = \frac{1}{3} h^5 + O(h^6) \text{ , } f_3(h) = \frac{1}{5} h^5 + O(h^6) \text{ , } f_4(h) = 2h^2 + O(h^3). \]

Using remark 4.1, we should generically expect the scheme to converge at rate $O(h^2)$. In this particular case, $\nu(y)$ has the antiderivatives

\[ F(y) = \frac{1}{2} e^{-|y|} \text{ , } F'(y) = -\frac{1}{2} \text{sign}(y)e^{-|y|} \text{ , } F''(y) = \frac{1}{2} e^{-|y|}. \]

As we show in Appendix A, all of the $w_j$ can now be calculated as follows

\[ w_j = \begin{cases}
f_1(h) - F'(x_1) + \frac{1}{h}[F(x_2) - F(x_1)], & |j| = 1 \\
\frac{1}{h}[F(x_{j+1}) - 2F(x_j) + F(x_{j-1})], & 1 < |j| < M \\
F'(x_M) + \frac{1}{h}[F(x_{M-1}) - F(x_M)], & |j| = M
\end{cases}\]

and $w_0 = 0$. We also have that the integral $A$, defined in (4.7), can be directly computed and is given by

\[ A = e^{- LW}. \]

The integral $B_i$, defined in (4.9), can also be calculated directly and is given by

\[ B_i = \frac{1}{2} e^{x_i} \log(e^{-2LW} + e^{2x_i}) - e^{x_i} x_i + \frac{1}{2} e^{-x_i} \log(e^{-2LW} + e^{-2x_i}) + e^{-x_i} x_i. \]

We then have all the necessary quantities to implement the numerical scheme for the Dirichlet problem introduced in section 4.3. First note that the true solution of this problem is in fact $u(x) = \text{sech}(x)$; this can be confirmed by a straightforward integration. Fig. 1(a) shows a plot of the solution $u(x)$ and the forcing function $f(x)$. Fig. 1(b) shows the $L^\infty$ error between the numerical solution and the true solution for varying values of $L$ and $h$. We see that for fixed $L$ the scheme does indeed converge at an $O(h^2)$ rate.

6.2. Whole Real Line Problem. Consider the extended Dirichlet problem

\[ L u(x) = f(x), \quad x \in \mathbb{R} \]
Fig. 1: (a) Plot of the solution \( u(x) = \text{sech}(x) \) and the corresponding forcing function \( f(x) \). (b) Plot of the \( L^\infty \) error between the numerical solution and the true solution for varying values of \( L \); each curve represents a different choice in the spatial step size \( h \).

with kernel

\[ \nu(y) = \frac{1}{2} e^{-|y|}. \]

As the quantities \( f_k, w_j \) and \( A \) have been computed in the previous section, to implement the numerical scheme introduced in section 4.4, we only need to compute the quantities \( B^1_i \) and \( B^2_i \) that are defined in (4.13). For this, let us assume for the moment that

\[ g(x) = \frac{1}{|x|^p} \]

for some \( p > 0 \). We then have

\[ B^1_i = \frac{1}{g(-L)} \int_{-\infty}^{-L_W} g(x_i - y) \nu(y) \, dy \]

\[ = L^p \int_{-\infty}^{-L_W} \frac{1}{|x_i - y|^p} \frac{1}{2} e^{-|y|} \, dy \]

\[ = L^p \int_{-\infty}^{-L_W} \frac{1}{(x_i - y)^p} \frac{1}{2} e^y \, dy \]

where the last equality is obtained by noting that \( x_i > y \) for all \( y \in [-\infty, -L_W] \). Doing two changes of variables and simplifying yields that the above is equal to

\[ L^p \frac{1}{2} e^{x_i} \frac{1}{(L_W + x_i)^{p-1}} \int_1^\infty \frac{1}{z^p} e^{-(L_W + x_i)z} \, dz. \]

This last integral is exactly of the form of the generalized exponential integral function \( E_p \). We note that this function can be computed quickly to a given accuracy and there
are many public codes for doing exactly this. Thus, we have

\[ B_1^i = L^p \frac{1}{2} e^{x_i} \frac{1}{(L_W + x_i)^{p-1}} E_p(L_W + x_i). \]

Likewise, it can be shown that

\[ B_2^i = L^p \frac{1}{2} e^{-x_i} \frac{1}{(L_W - x_i)^{p-1}} E_p(L_W - x_i). \]

We’ve then shown that if there exists a solution \( u(x) \) that decays algebraically with order \( p_0 \) then the above numerical scheme should give a good approximation by setting \( p = p_0 \) in the definition of \( g \). To demonstrate this, we will apply the above scheme to a known solution. In particular, let

\[ f(x) = \frac{1}{1 + x^2} - \frac{1}{2} \frac{1}{1 + (x-a)^2} - \frac{1}{2} \frac{1}{1 + (x+a)^2} \]

for some constant \( a > 0 \) and note that

\[ \int_{-\infty}^{\infty} f(x) \, dx = 0, \quad \int_{-\infty}^{\infty} xf(x) \, dx = 0. \]

Hence we know a corresponding solution \( u(x) \) will exist. In fact, for this particular problem, it can be shown by direct substitution that

\[ u(x) = f(x) - \int_{-\infty}^{x} \int_{-\infty}^{w} f(y) \, dy \, dw \]

is a solution. Integrating directly gives

\[
\begin{align*}
    u(x) &= \left[ \frac{1}{1 + x^2} - \frac{1}{2} \frac{1}{1 + (x-a)^2} - \frac{1}{2} \frac{1}{1 + (x+a)^2} \right] + \frac{1}{2} \left[ \log(x^2 + 1) \right. \\
    & \quad - \frac{1}{2} \log \left( \left( x^2 - a^2 \right)^2 + 2(x^2 + a^2) + 1 \right) \left. - \frac{1}{2} x \left[ 2 \tan^{-1}(x) \right. \right. \\
    & \quad - \tan^{-1}(x + a) + \tan^{-1}(x - a) \left. \right] + \left[ \frac{a}{4} \pi - \frac{a}{2} \tan^{-1} \left( \frac{1 + x^2 - a^2}{2a} \right) \right].
\end{align*}
\]

Letting \( a = 1 \), we have that

\[ f(x) = -\frac{3x^2 - 2}{x^6 + x^4 + 4x^2 + 4} \]

\[ \sim -\frac{3}{x^4} \]

and by Taylor expanding about \( \infty \) it can be shown that

\[ u(x) \sim \frac{1}{2x^2} \]

as \( |x| \to \infty \). Choosing \( p = 2 \), all quantities in the numerical scheme have been computed and it can now be implemented. Fig. 2(a) shows a plot of the true solution \( u(x) \) and the forcing function \( f(x) \). Fig. 2(b) shows the \( L^\infty \) error between the numerical solution and the true solution for varying values of \( L \) and \( h \). We see that for sufficiently large \( L \) the scheme seems to converge at an \( O(h^2) \) rate as well.
6.3. Neumann Problem. Here we consider the Neumann problem

\[ L \ast u(x) = \bar{f}(x), \quad x \in \mathbb{R} \]

where \( \nu(x) = \frac{1}{2}e^{-|x|} \) and

\[ \bar{f}(x) = \begin{cases} 
  x^2 - \frac{2}{3}, & x \in (-1, 1), \\
  \frac{1}{x^4}, & x \in (-1, 1)^c. 
\end{cases} \]

In this case, it can be shown that the corresponding solution is given by

\[ u(x) = \begin{cases} 
  x^2 - \frac{(x^2-3)(x-1)(x+1)}{12} - \frac{5}{6}, & x \in (-1, 1), \\
  \frac{1}{x^4} - \frac{1}{6x^2}, & x \in (-1, 1)^c. 
\end{cases} \]

Note that both \( \bar{f} \) and \( u(x) \) decay algebraically at the same rate as before; namely, \( \bar{f} \sim \frac{1}{x^4} \) and \( u(x) \sim \frac{1}{x^4} \). Hence, we can apply the numerical method from the previous section without change. Further note that \( \bar{f} \) and \( u(x) \) are not continuous nor differentiable at \( x = \pm 1 \); see Fig. 3(a). In deriving the numerical schemes from previous sections, we implicitly used that the solution \( u(x) \) was many times differentiable. This was done not only to derive formulas but also to get the \( O(h^2) \) truncation error. Since for this particular example differentiability doesn’t hold, we might expect that the order of convergence of the scheme is no longer \( O(h^2) \). Indeed, this is the case as Fig. 3(b) shows. Instead, it appears the scheme converges with rate \( O(h) \) for the various values of \( L \).

6.4. Comparison of the Boundary Conditions. In this section we’d like to test how the different boundary conditions, and their corresponding numerical schemes, compare in solving the problem on the whole real line. With this in mind
we consider the problem

\[ \mathcal{L} * u(x) = f(x), \quad x \in \mathbb{R}, \]

with kernel

\[ \nu(y) = \frac{1}{2} e^{-|y|} \]

and two different forcing functions. In the first case we take

\[ f(x) = \text{sech}(x) - \frac{1}{2} e^{-x} \log(1 + e^{2x}) - \frac{1}{2} e^x \log(1 + e^{2x}) + xe^x \]

for which we know the solution is \( u(x) = \text{sech}(x) \).

Fig. 4 shows the \( L^\infty \) error between the numerical solution and the true solution for the different boundary conditions. Fig. 4(a) shows the whole real line numerical scheme where we’ve used the asymptotic decay rate of \( \frac{1}{x^2} \) outside of \((-L, L)\). Fig. 4(b) corresponds to the Dirichlet problem with homogeneous boundary conditions: \( g(x) = 0 \) outside \((-L, L)\). Finally, Fig. 4(c) corresponds to the Neumann problem with homogeneous boundary conditions: \( g(x) = 0 \) outside \((-L, L)\). To be clear, we’re setting up the Neumann problem on a uniform grid in \((-2L, 2L)\) so that in order to use the previous numerical scheme we have to select \( L_W \geq 4L \). Although this requires roughly twice the computational cost of the other two methods it nevertheless compares the effectiveness of the boundary conditions. As the solution \( u(x) \) decays exponentially, we note that enforcing homogeneous boundaries condition is consistent with the original problem when \( L \) is large enough. With this in mind, it’s clear that for large enough \( L \) any of the three schemes retains the \( O(h^2) \) convergence rate.

As shown in Fig. 4(c), the Neumann formulation requires larger value of \( L \) to obtain a similar convergence behavior than the other formulations. It is a consequence
Fig. 4: $L^\infty$ error between the numerical solution and the true solution for varying values of $L$; each curve represents a different choice in the spatial step size $h$. Panel (a) shows the results when the algebraic decay is taken into account. Panel (b) corresponds to homogeneous Dirichlet boundary conditions. Panel (c) corresponds to homogeneous Neumann boundary conditions where we’ve taken $\tilde{L} = \frac{L}{2}$.

of $\tilde{f}$ being discontinuous even for large value of $L$. However the Neumann formulation is still expected to converge with a $O(h^2)$ rate as the function $f$ will appear continuous to machine precision when $L$ is large enough.

In the second case we take

$$f(x) = \frac{1}{1 + x^2} - \frac{1}{2} \frac{1}{1 + (x - a)^2} - \frac{1}{2} \frac{1}{1 + (x + a)^2}$$

with $a = 1$ for which we also know the solution. Fig. 5 is the companion figure to Fig. 4. Fig. 5(a) shows the whole real line numerical scheme where we’ve used the asymptotic decay rate of $\frac{1}{x^2}$ outside of $(-L, L)$. Fig. 5(b) corresponds to the Dirichlet problem with homogeneous boundary conditions: $g(x) = 0$ outside $(-L, L)$. Finally, Fig. 5(c) corresponds to the Neumann problem with homogeneous boundary conditions, $g(x) = 0$ outside $(-L, L)$, and we computed this numerically in the same way as was described in the previous paragraph. As the use of exact solutions to set boundary conditions is not feasible and realistic for physical applications, we use
Fig. 5: $L^\infty$ error between the numerical solution and the true solution for varying values of $L$; each curve represents a different choice in the spatial step size $h$. Panel (a) shows the results when the algebraic decay is taken into account. Panel (b) corresponds to homogeneous Dirichlet boundary conditions. Panel (c) corresponds to homogeneous Neumann boundary conditions where we’ve taken $\tilde{L} = \frac{L}{2}$.

homogeneous conditions for the Dirichlet and Neumann problems. It allows us to compare the behavior of the three schemes when the solutions is not exponentially decaying and that only its order of algebraic decay is known for large $x$. Unlike the previous case the situation here is much different. Namely, the whole real line method is by far more accurate than either of the other two. For the Dirichlet condition it’s because of the slow algebraic decay of the solution; on the domains considered $u(x)$ does not fall below $10^{-4}$, making this a lower bound on the error for any values of $h$. For the Neumann problem it’s even worse because, in addition to the slow decay rate, we have a discontinuity which is detectable to machine precision for all values of $L$ considered. Hence, decreasing $h$ will not decrease the error because the discontinuity will not vanish.
6.5. Dirichlet Problem with Not Strictly Positive Kernel. Consider the Dirichlet problem

\[
\begin{aligned}
L \ast u(x) &= f(x), \quad x \in (-L, L), \\
u(x) &= \text{sech}(x), \quad x \in (-L, L)^c,
\end{aligned}
\]  

with

\[
\nu(y) = \frac{3}{2} e^{-|y|} - 2 e^{-2|y|},
\]

\[
f(x) = 4 e^{-x} + \frac{1}{\cosh(x)} - \frac{3 \ln(e^{2x} + 1) e^{-x}}{2} + 2 e^x \left(2 \tan^{-1}(e^x) e^{-x} - \pi e^x + 2\right) - 4 \tan^{-1}(e^x) e^{-2x} + \frac{3 e^x (2 x - \ln(e^{2x} + 1))}{2}.
\]

Then by direct calculation, we have that

\[
\begin{aligned}
f_1(h) &= \frac{1}{h^2} e^{2h} \left(2 h^2 + 2 h + 1\right) - \frac{3 e^{-h} \left(h^2 + 2 h + 2\right)}{2} + \frac{5}{2} = \frac{1}{6} h + O(h^2), \\
f_2(h) &= -\frac{1}{6} h^5 + O(h^6), \quad f_3(h) = -\frac{1}{10} h^5 + O(h^6), \quad f_4(h) = \frac{1}{2} h^2 + O(h^3).
\end{aligned}
\]

Hence, we should generically expect the scheme to converge at rate \(O(h^2)\).

In this particular case, \(\nu(y)\) has the antiderivatives

\[
F(y) = \frac{3}{2} e^{-|y|} - \frac{1}{2} e^{-2|y|}, \quad F'(y) = -\text{sign}(y) \left(\frac{3}{2} e^{-|y|} - e^{-2|y|}\right), \quad F''(y) = \frac{3}{2} e^{-|y|} - 2 e^{-2|y|},
\]

so that now all of the \(w_j\) can be calculated. We also have that the integral \(A\) can be directly computed and is given by

\[
A = 3 e^{-2Lw} - 2 e^{-4Lw}.
\]

The integral \(B_i\) can also be calculated directly and is given by

\[
B_i = 4 e^{-2x_i} \tan^{-1}
\left(\frac{3 e^{-x_i} \left(2 x_i + \ln(e^{-2L} + e^{-2x_i})\right)}{2} - 3 e^{x_i} \left(2 x_i - \ln(e^{-2L} + e^{2x_i})\right) - 4 e^{x_i} \left(e^{-L} - \tan^{-1}(e^{-L} e^{-x_i}) e^{x_i}\right).
\]

We then have all the necessary quantities to implement the numerical scheme for the Dirichlet problem. First note that the true solution of this problem is in fact \(u(x) = \text{sech}(x)\); this can be confirmed by a straightforward integration. Fig. 6(a) shows a plot of the solution \(u(x)\) and the forcing function \(f(x)\). Fig. 6(b) shows the \(L^\infty\) error between the numerical solution and the true solution for varying values of \(L\) and \(h\). We see that for fixed \(L\) the scheme does indeed converge at an \(O(h^2)\) rate.

7. Conclusion. In this paper we consider integro-differential equations that model the evolution process of quantities that experience a nonlocal form of dispersion. In particular, we look at diffusion processes that are modeled using convolution kernels that do not have compact support and decay exponentially at infinity. We develop algorithms for finding the steady states of these systems.
In contrast to previous methods which assume local boundary data, our numerical method accounts for the correct nonlocal nature of the boundary conditions. We present three numerical schemes addressing the case of nonlocal Dirichlet boundary conditions (DP), Neumann boundary conditions (NP), and the whole real line problem (RP).

When the equation is posed on the whole real line, we show that a unique solution exist, provided the right hand side decays at least algebraically and has zero mean and first moment. More importantly, the result shows that there is a relation between the decay of the right hand side and the decay of the solution. This information is then used to approximate the solution outside the computational domain and thus develop a scheme for RP.

Since nonlocal Neumann boundary conditions require us to approximate the solution outside a bounded domain, the numerical schemes for NP and RP are almost identical. In both cases the scheme boils down to inverting a matrix equation. We are able to show using a Neumann series that this matrix is invertible provided the convolution kernel is nonnegative. This also proves the convergence of the scheme.

For the Dirichlet problem, we consider kernels that can take on negative values, but that have positive tails. We show, using the theory of Toeplitz matrices, that this is enough to prove the convergence of the our numerical scheme. This is an improvement over previous results which are based on maximum principles and therefore require nonnegative kernels with compact support.

Finally, for applications where the model equations are posed on the whole real line, there is always a question of what are the best boundary conditions one can use to approximate solutions. Here we present a numerical scheme that does not require explicit boundary conditions. However, we do find that in certain circumstances, mainly when the right hand side decays exponentially, the Dirichlet problem provides a more efficient method for approximating the whole real line problem. First, because one can reduce the size of the computational domain, and secondly one does not have to approximate the solution outside this domain, i.e. setting the solution to zero gives
Appendix A. Calculation of $w_j$. Here we derive formulas for the weights $w_j$ considered earlier. Assume that $\nu(y)$ has two integrable antiderivatives. Namely, assume there exists a function $F$ such that $F''(y) = \nu(y)$. We can then use integration by parts to show the following results.

In the first case, assume $1 < |j| < M$, then

$$
\int_{h \leq |y| \leq L} T(y - x_j) \nu(y) \, dy = \int_{x_{j-1}}^{x_{j+1}} T(y - x_j) \nu(y) \, dy
$$

$$
= \int_{-h}^h T(z) \nu(z + x_j) \, dz
$$

$$
= \frac{1}{h} \left[ F(x_{j+1}) - 2F(x_j) + F(x_{j-1}) \right].
$$

The second line is obtained by the change of variables $z = y - x_j$. The third line is obtained by doing integration by parts twice and using $\nu = F''$.

When $j = 1$, we don’t integrate over the full hat function because half of the hat function is not in the domain of $|y| \geq h$. It reads:

$$
\int_{h \leq |y| \leq L} T(y - x_1) \nu(y) \, dy = \int_{x_1}^{x_2} T(y - x_1) \nu(y) \, dy
$$

$$
= \int_{0}^{h} T(z) \nu(z + x_1) \, dz
$$

$$
= F'(x_1) + \frac{1}{h} \left[ F(x_2) - F(x_1) \right].
$$

When $j = M$ a similar argument shows

$$
\int_{h \leq |y| \leq L} T(y - x_M) \nu(y) \, dy = F'(x_M) + \frac{1}{h} [F(x_{M-1}) - F(x_M)].
$$

Finally, because both $\nu(y)$ and $T(y)$ are even we have

$$
\int_{h \leq |y| \leq L} T(y - x_{-j}) \nu(y) \, dy = \int_{h \leq |y| \leq L} T(y + x_j) \nu(y) \, dy
$$

$$
= \int_{h \leq |z| \leq L} T(-z + x_j) \nu(-z) \, dz
$$

$$
= \int_{h \leq |z| \leq L} T(z - x_j) \nu(z) \, dz.
$$

Looking at the definitions in the previous sections, this immediately gives

$$
w_{-j} = w_j.
$$

To summarize, we’ve shown that if the kernel $\nu$ has the appropriate antiderivatives
Then the weights $w_j$ are given explicitly by

$$\begin{align*}
w_j &= \begin{cases} f_1(h) - F'(x_1) + \frac{1}{h}[F(x_2) - F(x_1)], & |j| = 1 \\
\frac{1}{h}[F(x_{j+1}) - 2F(x_j) + F(x_{j-1})], & 1 < |j| < M \\
F'(x_M) + \frac{1}{h}[F(x_{M-1}) - F(x_M)], & |j| = M 
\end{cases}
\end{align*}$$

with $w_0 = 0$.
