DOI: https://doi.org/10.22271/chemi.2020.v8.i4ab.10001

Abstract
Rice (Oryza sativa L.) is an important food crop extensively grown in India. The average production and productivity are low in both India and Tamil Nadu. Several factors are responsible for reducing the yield of transplant rice. Among them, weed infestation is one of the major threats for low productivity of transplanted rice and subsequently on pulses yield. Therefore, field experiments were conducted at Tamil Nadu Rice Research Institute, Aduthurai during 2017-2018 in both kharif and rabi seasons with different doses of pyrazosulfuron-ethyl (20, 30 and 42.85 g ha⁻¹) which compared with Pretilachlor dichloride 50% EC, Butachlor 50% EC, Hand weeding twice and untreated check. The results of the experiments revealed that application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha⁻¹ as post emergence controlled the weed menace in all stages of transplanted rice and also succeeding crop of blackgram in Cauvery Delta regions. Higher yield could be obtained under Pyrazosulfuron ethyl 70% WDG @ 30 g ha⁻¹ as post emergence applied plot.

Keywords: Transplanted rice, weed menace, herbicides, yield, nutrient uptake, succeeding crop blackgram

Introduction
Rice (Oryza sativa L.) is a major staple food for more than 60 per cent of the world population, providing energy for about 40% of the world population where every third person on earth consumes rice every day in one form or other (Ramesha, et al. 2017) [9]. It is extensively grown in tropical and sub tropical regions of the world. It is cultivated in area of 44.0 million hectares with an annual production of 104.3 million tons in India. Its production has been found to be distributed as 91.5 million tons in kharif and 12.8 million tons in rabi season. The productivity in India is very low (2.37t ha⁻¹) as compared to other rice growing countries like Japan (6.35t ha⁻¹), Australia (6.22t ha⁻¹), Spain (6.16t ha⁻¹), Egypt (5.0 t ha⁻¹) and China (5.2t ha⁻¹). In Tamil Nadu, rice is grown in an area of 2.04 million hectare with total production of 9.98 million tonnes. In Cauvery Delta Zone (CDZ), major crop is rice which is grown in an area of 14.47 lakh ha which contributes 11 per cent of the total area of Tamil Nadu with average productivity of 2.8 tonnes ha⁻¹. The Cauvery Delta Zone includes Thanjavur, Nagappattinam, Tiruvarur, Trichy and parts of Karur, Ariyalur, Pudukottai and Cuddalore districts of Tamil Nadu. The practice of double cropping of rice in kurvai (June - September) and thaladi (October - February) is on the increase because of the development of short and medium duration high yielding rice varieties (Subrahmaniyam et al., 2016) [13]. Weeds are the major cause of yield reduction in rice. Hand weeding is the traditional weed control measure and still being the most popular in rice. However, due to high labour cost, non-availability of labour and huge time requirement for manual weeding, farmers are inevitable to go for other alternative measures like chemical weed control. Many herbicides are being used successfully for weed control in transplanted rice as pre-emergence spray. New herbicides are available in the market and use of herbicides of different composition is desirable to reduce the problem of residue buildup, shift in weed problem (Rajkhowa., et al. 2006) [10] and development of herbicide resistance in weeds (Rao, 1999, Saha., et al. 2006) [11, 12]. The recent trend of herbicide use is to find out an effective weed control measure by using low dose high efficiency herbicides which will not only reduce the total volume of herbicide use but also the application become easier and economical (Pal and Banerjee, 2007) [7].
The herbicide pyrazosulfuron ethyl 10% WP has both foliar and soil activity (Rajkhowa., et al. 2006). It is generally recommended as a pre-emergence herbicide in transplanted rice (Angiras and Kumar, 2005). Studies on bio-efficacy and phytotoxicity of pyrazosulfuron ethyl 10% WP for pre-emergence weed control in transplanted rice are scanty. The present experiment was therefore undertaken to study the bio-efficacy and phytotoxicity of pyrazosulfuron ethyl in pre-emergence control of major weeds in transplanted rice based cropping system (succeeding crop of blackgram) and to determine an optimum dosage of application that can be recommended to rice growing farmers.

**Materials and Methods**

Field experiments were conducted at Tamil Nadu Rice Research Institute, Aduthurai during 2017-2018 in both kharif and rabi seasons. The experimental area located at latitude of 11° N, longitude of 79° E and an altitude of 19.5 m above MSL. The region is characterized by a sub-tropical climate with a hot dry summer (March -June) and extended wet period from September to February. The mean annual rainfall is about 1176 mm majority of which was received during North East Monsoon. The mean annual maximum and minimum temperatures were 33.3 °C and 23.5 °C. The mean annual relative humidity was 89 per cent. The mean wind velocity and bright sunshine hours were 5.2 kmph and 6.7 hours day⁻¹. The sown rice variety was ADT 43 of 120 days duration. The crop was transplanted during 1st week of August at a spacing of 20 x 15 cm and harvested during 2nd week of October in both the years. Full doses of phosphorus through single super phosphate (SSP) and potash through muriate of potash (MOP) each 30 kg/ha along with 25% recommended doses of nitrogen (60 kg/ha) through urea were applied at basal during the final land preparation. Remaining 75% nitrogen was applied through urea in three equal splits at 25, 45 and 65 DAT. The different weed management treatments were imposed as the technical programme as furnished below.

| Treatments | Dosage (a/ha (gm)) | Formulation/ha (gm) | Water for Dilution (in litres) |
|------------|-------------------|---------------------|-----------------------------|
| T1 Pyrazosulfuron Ethyl 70% WDG | 14 | 20 | 500 |
| T2 Pyrazosulfuron Ethyl 70% WDG | 21 | 30 | 500 |
| T3 Pyrazosulfuron Ethyl 70% WDG | 30 | 42.85 | 500 |
| T4 Pyrazosulfuron Ethyl 70% WDG (UPL) | 21 | 30 | 500 |
| T5 Pretillachlor dichloride 50% EC | 500 | 1000 | 500 |
| T6 Butachlor 50% EC | 1250 | 2500 | 250 |
| T7 Hand Weeding (20 DAS & 40 DAS) | - | - | 500 |
| T8 Untreated Control (Weedy Check) | - | - | 500 |
| T9 *Pyrazosulfuron Ethyl 70% WDG | 42 | 60 | 500 |
| T10 *Pyrazosulfuron Ethyl 70% WDG | 84 | 120 | 500 |

An area of 0.25 m² was selected randomly at two spots by throwing a quadrat of 0.5 x 0.5 m, weed species were counted from that area and density was expressed in number per m². The collected weeds were first sun-dried and then kept in an electric oven at 700°C till the weight became constant and weed biomass was expressed as g/ m². Comparison of treatment means for significance at 5% level was done using the critical differences as suggested by Gomez and Gomez (1984). Data on grain yield were recorded from the net plot. Weed control efficiency (WCE) was worked out using the formula as suggested by (Mani et al. 1973, Gill and Vijayakumar, 1969).

**Weather and climate during the cropping period**

During kharif 2017, the amount of rainfall received during cropping season was 474.6 mm in 27 rainy days. The maximum temperature ranged from 32.1 to 37 °C, while minimum temperature ranged from 23.8 to 26.3 °C, during kharif 2017. In kharif 2017, the relative humidity ranges from 75 to 94 per cent and 46 to 76 per cent during forenoon and afternoon respectively. The mean sunshine hours was 5.7 hours day⁻¹. During rabi 2017, the amount of rainfall received during cropping season was 770.8 mm in 29 rainy days. Similar trend was also observed during 2018.

**Results and Discussions**

**Weed flora of the experimental area**

The predominant grassy weeds associated with transplanted rice are Echinochloa colona (L.), Echinochloa crusgalli (L.), Cynodon dactylon Pers and Panicum repens (L.). Cyperus iria (L.), Cyperus difformis (L.), Cyperus rotundus (L.) and Fimbristylis miliacea (L.) among sedges and Eclipta alba (L.), Marsilea quadrifolia, Ludwigia parviflora and Commelina benghalensis among broad leaved and aquatic weeds. However, the effect of Pyrazosulfuron Ethyl was assessed on the weeds such as Echinochloa spp, Cyperus rotundus, Cyperus iria, Cyperus difformis, Ludwigia parviflora, Fimbristylis miliacea during 20, 40 and 60 DAT during 2017 and 2018 seasons. The number of dominant broad-leaved, grass and sedge weeds was gradually decreased with the increase of doses of tested herbicide pyrazosulfuron-ethyl in all the three dates of observation. Better weed control was observed with application of maximum dose of the tested herbicide. Pyrazosulfuron-ethyl is highly selective to rice crop so also called as rice herbicide. It control grasses, sedges and broad leaf weed in rice. Grasses includes Echinochloa colona, Panicum spp., sedges includes Fimbristylis miliacea, Cyperus spp., and broad leaf weeds includes Ludwigia parviflora, Marsilea quadrifolium, Alternanthera sessilis etc. Pyrazosulfuron is absorbed by roots or leaves and translocated to meristem which inhibits ALS/AHAS enzyme catalyzing the biosynthesis of three essential branched-chain amino acid, namely leucine, valine and isoleucine they stops cell division of roots and check the plant growth (Priyanka Kabdal et al. 2018).

**Effect of weed management practices on weed characters**

**Weed density**

The weed density (Nos./m²) was recorded for different weed species during 20,40 and 60 Days After Transplanting during Kharif 2017 and 2018. The different weed management practices were significantly on weed density under various

International Journal of Chemical Studies

http://www.chemijournal.com
stages of the crop growth of transplanted rice. In kharif 2017, among different weed species, higher weed density was observed under Echinochloa spp in grasses, Cyperus rotundus in sedges and Ludwigia parviflora in broadleaved weeds (Table 2 and 3). Similar trend was also recorded in Kharif 2018 (Fig.1). In both seasons, higher weed density was noticed under untreated check. Application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha$^{-1}$ as post emergence reduced the weed density of weed species in all stages of crop (20,40 and 60 DAT) which was followed Pyrazosulfuron ethyl 70% WDG @ 21 g ha$^{-1}$ compared to other treatments. Hand weeding twice controlled weed from initial stage to harvest. Similarly, application of Pyrazosulfuron-ethyl at 20 and 25 g/ha significantly reduced weed density and total weed biomass of Cyperus iria, Echinochloa colona etc. when applied at 3 to 10 days after transplanting were reported by Chopra and Chopra 2003 $[^2]$. 

**Fig 1:** Weed density of different weed species wise during kharif 2018

**Weed dry weight (g/m$^2$)**
The different weed management practices significantly influenced on the weed dry weight in all stages crop during both kharif seasons. Application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha$^{-1}$ as post emergence reduced the weed dry weight of 17.82, 17.14 and 20.19 g m$^2$ during 20,40 and 60 DAT respectively which was followed Pyrazosulfuron ethyl 70% WDG @ 21 g ha$^{-1}$ compared to other treatments. Higher weed dry weight was recorded in untreated plots in all stages. Similar trend was observed in kharif 2018 (Fig.2).

**Fig 2:** Weed dry weight and weed control efficiency in transplanted rice during kharif 2018

**Weed control efficiency**
The different weed management practices significantly influenced on the weed control efficiency in all stages crop during both kharif seasons. Application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha$^{-1}$ as post emergence recorded higher weed control efficiency of 57.32, 76.74 and 88.34 per cent during 20,40 and 60 DAT respectively which was followed Pyrazosulfuron ethyl 70% WDG @ 21 g ha$^{-1}$ compared to other treatments. Higher weed control efficiency was recorded in all stages under hand weed twice on 20 and 40 DAS. Similar trend was observed in kharif 2018 (Fig.2).

**Effect of weed management practices on growth & yield attributes of transplanted rice**
All growth and yield attributes of transplanted rice were significantly influenced by different weed management practices in both kharif seasons. The highest rice grain yield (6266 kg/ha) was recorded in application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha$^{-1}$ as post emergence which was followed Pyrazosulfuron ethyl 70% WDG @ 21 g ha$^{-1}$ compared to other treatments (5683 kg/ha). The increase in grain yield under this treatment was due to less weed density and weed biomass as compared to all other treatments tried in this study and also mainly due to higher trend in plant height, No. of tillers and No. of productive tillers. Lowest grain yield of rice was observed in untreated check (4240 kg/ha) which
was due to high weed density and biomass (Table 4, 4a). Similar trend was observed in kharif 2018. The increase in grain yield under this treatment was due to less weed density and weed biomass as compared to all other treatments. Das (2008) found that the application of Pyrazosulfuron in general increase vigor of rice plants in terms of more number of tillers and better grain filling resulting in higher yield.

**Effect of weed management practices on growth and yield attributes of succeeding blackgram (Table 5)**

All growth and yield attributes of succeeding blackgram were significantly influenced by different weed management practices in both kharif seasons.

**Application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha⁻¹**

as post emergence was recorded increased trend of growth attributes such as plant height (28.10 cm), No. of branches (7.3), No. of pods (36.78) in turn increased higher pod yield (940.12 kg/ha) which was followed Pyrazosulfuron ethyl 70% WDG @ 21 g ha⁻¹ compared to other treatments (835 kg/ha). The increased growth and yield attributes under this treatment is mainly due to lower weed menace in the proceeding crop of transplanted rice during kharif seasons. The same trend was also observed in second year (kharif 2018 and Rabi 2018) (Fig.3).

Nutrient availability and uptake by crops (Transplanted rice and blackgram)
The available nitrogen, phosphorus and potassium ranged from 176 to 192.8 kg/ha, from 46.1 to 64.1 kg/ha and from 125 to 137.3 kg/ha respectively were recorded after harvest of the crops during kharif 2017. In case of second year, availability of nitrogen and phosphorus were higher than potassium. Application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha⁻¹ as post emergence was recorded increased trend of nutrients uptake by both proceeding and succeeding crops of transplanted rice and blackgram respectively (Table 6, 6a & 7).

Phyto-toxicity
Visual observations viz., leaf injury, yellowing, stunning, necrosis, vein clearing, wilting, epinasty and hyponasty at 1,3,7 and 10 days after application of treatments were not noticed in both proceeding and succeeding crops of transplanted rice and blackgram respectively.

Conclusion
The results of two years experiments revealed that application of Pyrazosulfuron ethyl 70% WDG @ 30 g ha⁻¹ as post emergence controlled the weed menace in all stages of transplanted rice and also succeeding crop of blackgram in Cauvery Delta regions which inturn resulted in higher yield in both transplanted rice and succeeding blackgram could be obtained under Pyrazosulfuron ethyl 70% WDG @ 30 g ha⁻¹ as post emergence applied plot.
