Abstract

Tetrahydrobiopterin (BH₄), which fosters the formation of and stabilizes endothelial NO synthase (eNOS) as an active dimer, tightly regulates eNOS coupling / uncoupling. Moreover, studies conducted in genetically-modified models demonstrate that BH₄ pulmonary deficiency is a key determinant in the pathogenesis of pulmonary hypertension. The present study thus investigates biopterin metabolism and eNOS expression, as well as the effect of sepiapterin (a precursor of BH₄) and eNOS gene deletion, in a mice model of hypoxic pulmonary hypertension. In lungs, chronic hypoxia increased BH₄ levels and eNOS expression, without modifying dihydrobiopterin (BH₂, the oxidation product of BH₄) levels, GTP cyclohydrolase-1 or dihydrofolate reductase expression (two key enzymes regulating BH₄ availability). In intrapulmonary arteries, chronic hypoxia also increased expression of eNOS, but did not induce destabilisation of eNOS dimers into monomers. In hypoxic mice, sepiapterin prevented increase in right ventricular systolic pressure and right ventricular hypertrophy, whereas it modified neither remodelling nor alteration in vasomotor responses (hyper-responsiveness to phenylephrine, decrease in endothelium-dependent relaxation to acetylcholine) in intrapulmonary arteries. Finally, deletion of eNOS gene partially prevented hypoxia-induced increase in right ventricular systolic pressure, right ventricular hypertrophy and remodelling of intrapulmonary arteries. Collectively, these data demonstrate the absence of BH₄/BH₂ changes and eNOS dimer destabilisation, which may induce eNOS uncoupling during hypoxia-induced pulmonary hypertension. Thus, even though eNOS gene deletion and sepiapterin treatment exert protective effects on hypoxia-induced pulmonary vascular remodelling, increase on right ventricular pressure and / or right ventricular hypertrophy, these effects appear unrelated to biopterin-dependent eNOS uncoupling within pulmonary vasculature of hypoxic wild-type mice.

Introduction

Pulmonary hypertension is characterized by functional (vasoconstriction, endothelial dysfunction) and structural (remodelling) alterations in the pulmonary vasculature [1-3], leading to right ventricular hypertrophy, right ventricular failure and ultimately death. The underlying mechanisms include alterations in local production and effects of vasoactive factors, but remain yet not fully understood.

Endothelial NO synthase (eNOS)-derived nitric oxide (NO) exerts vasculoprotective effects [4]. Tetrahydrobiopterin (BH₄) is a cofactor of eNOS, which fosters dimer formation and stabilizes the enzyme as an active dimer, allowing optimal oxidation of L-arginine into NO [5-7]. A decrease in BH₄ availability results in eNOS uncoupling, a dysfunctional state in which, following dimer destabilisation, eNOS monomers produce reactive oxygen species (ROS) rather than NO. This contributes to vascular oxidative stress and dysfunctions in many cardiovascular diseases [5-7]. BH₄ bioavailability depends on a balance between de novo synthesis by GTP cyclohydrolase-1 (GTPCH-1, the first and limiting step for BH₄ biosynthesis from GTP), loss of BH₄ (due to oxidation of BH₄, etc.) and sepiapterin (a precursor of BH₄) metabolism.
into the dihydrobiopterin BH$_2$ and recycling of BH$_2$ into BH$_4$ by dihydrofolate reductase (DHFR) [7]. Even in the absence of BH$_4$ deficiency, elevated levels of BH$_2$ can compete with BH$_4$ for binding to eNOS, resulting in eNOS uncoupling [8,9]. Rather than the absolute BH$_4$ concentration, both eNOS / BH$_4$ stoichiometry and biotin-dependent biotin reductase and biotin reductase status appear as key determinants of eNOS uncoupling [7,10].

Local BH$_4$ availability is crucial in maintaining pulmonary vascular homeostasis. Indeed, increased BH$_4$ synthesis prevents pulmonary hypertension [11]. Conversely, BH$_4$ deficiency elevates pulmonary vascular tone by decreasing eNOS activity and NO bioactivity, thus promoting pulmonary vascular remodelling, pulmonary hypertension and right ventricular hypertrophy [11,12]. These data were obtained in mice models, in which tissue BH$_4$ levels were either decreased by reduced expression of GTPCH-1, or increased by targeted overexpression of GTPCH-1. Only few studies have investigated whether alterations in biopterin metabolism occur in pathophysiological relevant models of pulmonary hypertension. In a lamb model of persistent pulmonary hypertension of the newborn, an increase in oxidative stress due to uncoupled eNOS and elevated levels of BH$_2$ likely contributes to impaired NO-dependent pulmonary vasodilatation [13,14].

In the present study, we analysed biotin metabolism and eNOS expression in a model of hypoxia-induced pulmonary hypertension. This model is clinically relevant, since chronic hypoxia is one of the major causes of sustained pulmonary hypertension in patients with advanced chronic obstructive pulmonary disease [15]. In mice exposed to chronic hypoxia, in which ROS are elevated in the pulmonary vasculature [16,17], we investigated lung levels of BH$_2$, BH$_4$, expression of eNOS (including dimer / monomer ratio), GTPCH-1 and DHFR in lung and/or intrapulmonary arteries, during hypoxic challenge. The effect of sepiapterin (a precursor of BH$_4$ via DHFR [7]) and eNOS gene deletion on pulmonary vasomotor responses, pulmonary vascular remodelling, right ventricular systolic pressure and hypertrophy was also evaluated.

Materials and Methods

Animals

This investigation conformed to the Guide for the Care and Use of Laboratory Animals (NIH Publication No. 85-23, revised 1996). Agreement (number A 33409) was obtained from our local ethics committee named Comité d'éthique régional d'Aquitaine (protocol number: AP 2/11/2005). Experiments were performed in 10 weeks old (20–25 g) male C57Bl/6 wild type (WT) mice (Elevage Janvier, Le Genest St Isle, France) and male C57Bl/6 eNOS$^{-/-}$ mice [18,19]. Some WT and eNOS$^{-/-}$ mice were housed in a hypobaric chamber at 380 mmHg for 30 min for animal care and cleaning. Control mice (normoxic group) were housed in ambient atmospheric conditions. For some experiments, sepiapterin (30 mg / kg) was administered orally by gavage, one day before exposure to hypoxia and every other day during hypoxia, at each chamber opening. Consequently, the dose of sepiapterin was adapted from previous studies [20,21].

After cervical dislocation, the heart and lungs were removed and placed in cold Krebs solution (composition in mM: NaCl 119; KCl 4.7; CaCl$_2$ 1.5; MgSO$_4$ 1.17; KH$_2$PO$_4$ 1.18; NaHCO$_3$ 25; and glucose 5.5).

Measurement of pulmonary BH$_4$ and BH$_2$

Mice lungs were homogenized in ice-cold lysis buffer (0.1 mM Tris-HCl, pH 7.6, containing 5 mM ethylenediamine tetraacetic acid, 0.3 mM KCl, 5 mM 1,4-dithioerythritol, 0.5 mM Pefabloc, and 0.01% saponin). Samples were oxidized under either acidic conditions (with 0.2 M HCl containing 50 mM I$_2$) or alkaline conditions (with 0.2 M NaOH containing 50 mM I$_2$). The biotin content was assessed by HPLC with fluorescence detection (350-nm excitation, 450-nm emission). The BH$_4$ concentration was calculated by subtracting the biotin peak resulting from alkaline oxidation (accounting for BH$_2$) from the biotin peak resulting from acidic oxidation (accounting for both BH$_2$ and BH$_4$) [22]. Biotin concentrations were expressed as picomoles per milligram of protein.

Expression of GTPCH-1, DHFR, total eNOS and eNOS dimer / monomer

For Western-blotting, tissues were homogenized in ice-cold lysis buffer (50 mM Tris, pH 7.5, 150 mM NaCl, 0.1% SDS, 0.5% deoxycholate, 1% Nonidet P-40) containing protease inhibitors and 1 mM phenylmethylsulfonyl fluoride. Homogenates (30 µg of proteins) were separated by electrophoresis on SDS-PAGE (at 4°C for eNOS dimer / monomer analysis; [23]) and transferred to PVDF membrane. After blocking, membranes were incubated with antibodies against eNOS, DHFR, GTPCH-1, or β-actin and goat anti mouse IgG peroxidase conjugated antibody. Protein bands were visualized by chemiluminescence and quantified using Image J software (National Institutes of Health, Bethesda, MA, USA). Results were expressed as the signal ratio of GTPCH-1, DHFR, total eNOS to β-actin, or of eNOS dimer to eNOS monomer.

For quantitative RT-PCR, total RNA were isolated from mouse lungs using the EZENA total RNA kit (Omega Bio-Tek, Norcross, GA). Total RNA (1 µg) were reverse-transcribed by using the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA) according to the manufacturer's instructions. Quantitative real-time RT-PCR amplification was performed in an iCycler IQ System (Bio-Rad Laboratories, Munich, Germany) using the ABsolute QPCR SYBR Green Fluorescein Mix kit (Thermo Fischer Scientific, Surrey, UK). The comparative threshold cycle (Ct) method was used for relative mRNA quantification [24]. Gene expression was normalized to the house-keeping gene GAPDH, and the amount of target gene mRNA expression in each sample was expressed relative to that of the control [25]. Primers were 5’- CCT TCC GCT ACC AGC CAG A-3’ (forward), 5’-CAG AGA TCT TCA CTG CAT TGG CTA-3’ (reverse) for mouse eNOS, and 5’-CTC AAC TAC ATG GTC TAC TAT TCT CA-3’ (forward), 5’-CCA TTC TCG GCC TTG ACT GT-3’ for GAPDH.

Wire myograph studies

Intrapulmonary arteries were mounted in a myograph as previously described [16,26]. Contraction to phenylephrine and relaxation to acetylcholine (after precontraction with 3.10^-4 M phenylephrine) were evaluated in the presence or absence of sepiapterin (10^-4 M; 60 min pre-incubation) or the NOS-synthase inhibitor N^-nitro-L-arginine methyl ester (L-NAME, 3.10^-4 M; 30 min pre-incubation).

Morphometric analysis of pulmonary arterioles

Left lungs were fixed in 4% paraformaldehyde, and dehydrated in increasing grade of ethanol. After delipidation with xylene, lungs were embedded in paraffin and cut into transverse sections (4 µm) which were stained with hematoxylin, eosin and orcein. Pulmonary vascular remodeling was assessed by measuring the percentage of wall thickness of the arterioles. All arterioles from one section of each mouse being associated with bronchioli were analyzed for their external diameter, external and internal areas. The diameter was analyzed along four axes across the center of the vessels being assessed for bronchioli were analyzed for their external diameter, external and internal areas. The diameter was analyzed along four axes across the center of the vessels and only arterioles with diameters inferior to 100 µm were taken into account. The wall thickness of all arterioles on each lung section from 4 to 7 mice was analyzed using Image J software. The percentage of wall thickness (%) wall thickness) was calculated as [(external wall areas) – (internal wall areas)] x 100/ external wall areas.

Right ventricular systolic pressure and hypertrophy

Mice were anesthetised (pentobarbital, 50mg/kg i.p.) and after thoracotomy, a heparin-filled hypodermic needle connected to a polyethylene catheter was placed into the right ventricular cavity by direct puncture of the right ventricle. Right ventricular systolic pressure was measured by use of a fluid-filled force transducer. The weight ratio: right ventricle / (left ventricle + septum) was calculated to assess hypoxia-induced right ventricular hypertrophy.

Drugs, reagents and antibodies

Acetylcholine, phenylephrine and L-NAME were purchased from Sigma (St Quentin-Fallavier, France), L-sepiapterin from Sigma (St Quentin-Fallavier, France), L-sepiapterin from Schircks Laboratories (Jona, Switzerland) and pentobarbital from Ceva (Libourne, France). Mouse monoclonal antibodies anti-eNOS and anti-DHFR were obtained from BD Transduction Laboratories (Le Pont de Claix, France), anti-GTPCH-1 from Santa Cruz Biotechnology (Heidelberg, Germany) and anti-β-actin from Sigma. Polyclonal goat anti mouse IgG peroxidase conjugated were purchased from Thermo Scientific (Illkirch, France).

Data analysis

Data were expressed as mean ± SEM of n experiments. Statistical evaluation was performed by the non-parametric Mann–Whitney test for bioterin concentrations, protein expression, morphometric analysis and right ventricular systolic pressure. Concentration-response curves were compared using analysis of variance. Student’s t test was used to measure statistical differences among weight ratio right

Results

Hypoxia-induced increase in right ventricular systolic pressure and right ventricular hypertrophy

Right ventricular systolic pressure was significantly increased in WT mice exposed to hypoxia for 10, 21 or 40 days (Table 1). Hearts from those mice also displayed a progressive right ventricular hypertrophy, as evidenced by a significant increase of the weight ratio right ventricle / (left ventricle + septum) (Table 1). These modifications are known to be correlated with the development of pulmonary hypertension.

BH4 and BH2 contents in lungs from hypoxic WT mice

BH4 levels significantly increased in lungs from WT mice exposed to hypoxia for 10, 21 or 40 days, compared to lungs from normoxic mice (Figure 1A). Whatever the duration of hypoxia, BH2 levels in lungs remained stable compared to control lungs (Figure 1B). Consequently, the BH4/BH2 ratio increased following chronic hypoxia, statistical significance being achieved at 10 and 40 days of chronic hypoxia, compared to normoxic mice.

GTPCH-1, DHFR and eNOS expression in lungs and intrapulmonary arteries from hypoxic WT mice

In lungs, protein expression of GTPCH-1 and DHFR remained unchanged in WT mice exposed to hypoxia for 10, 21 and 40 days, compared to normoxic controls (Figure 2AC). However, chronic hypoxia markedly up-regulated eNOS in lungs, at both protein (Figure 2E) and mRNA levels (Figure 2G). In intrapulmonary arteries, quite similar results were obtained (Figure 2BDF), except for GTPCH-1 expression which was slightly but transiently increased after 21 days of hypoxia, compared to normoxic controls (Figure 2B) and eNOS whose expression was not increased after 10 days of hypoxia (Figure 2F).

The dimer / monomer ratio of eNOS, which is an index of eNOS uncoupling, was investigated in intrapulmonary arteries of WT mice exposed to hypoxia. As shown in Figure 3A, this ratio was unchanged after 10 days of hypoxia, but increased after 21 or 40 days of hypoxia (times at which BH4 content and
BH4 and eNOS during Hypoxic Pulmonary Hypertension

monomers within the intrapulmonary vasculature. As expected, sepiapterin, a precursor of BH4, further enhanced eNOS dimerization in intrapulmonary arteries from hypoxic mice (Figure 3A; after 40 days of hypoxia, the band corresponding to the monomer was even not detectable, not allowing accurate quantification of dimer / monomer ratio of eNOS). In right or left ventricles from normoxic or hypoxic (21 days) mice, no change in the dimer / monomer ratio of eNOS was evidenced (Figure 3B).

Effect of sepiapterin on hypoxia-induced alterations of pulmonary vasomotor responses, pulmonary vascular remodelling, right ventricular pressure and hypertrophy in WT mice

Endothelium-dependent relaxation to acetylcholine was progressively decreased in intrapulmonary arteries from WT mice exposed to hypoxia (for 10, 21 and 40 days), compared to normoxic controls (Figure 4). In arteries from both normoxic and hypoxic mice, acetylcholine-induced relaxations were almost abolished by the NOS inhibitor L-NAME (Figure 4), indicating that it was mediated by NOS-derived NO. Sepiapterin, in conditions in which it did not modify relaxation to acetylcholine in intrapulmonary arteries from normoxic mice but markedly increased dimer / monomer ratio of eNOS in intrapulmonary arteries from hypoxic mice (see Figure 3), failed to normalize hypoxia-induced impaired relaxation to acetylcholine (Figure 4).

Phenylephrine-induced contraction was exacerbated following chronic hypoxia (Figure 5). The NO-synthase inhibitor L-NAME exacerbated hypoxia-induced hyper-reactivity to phenylephrine in intrapulmonary arteries (Figure 5), indicating that contractile responses were modulated by NOS-derived NO. Sepiapterin also failed to normalize hypoxia-induced impaired contraction to phenylephrine (Figure 5).

As expected, chronic hypoxia (21 days) significantly increased medial thickness in intrapulmonary arterioles (Figures 6A and B), to a similar extend than in previous mice studies [27,28]. Chronic oral treatment with sepiapterin, wich tended to increase lung BH4 content from 23.4 ± 0.2 to 28.5 ± 2.4 pmol / mg protein (p = 0.10), did not prevent hypoxia-induced increase in pulmonary arterioles wall thickness (Figures 6A and B). However, sepiapterin prevented hypoxia-induced increase in right ventricular systolic pressure (Figure 6C) and right ventricular hypertrophy (Figure 6D). In normoxic WT mice, both wall thickness of pulmonary arterioles and weight ratio right ventricle / (left ventricle + septum) were not modified by chronic oral treatment with sepiapterin (data not shown).

Pulmonary vasomotor responses, pulmonary vascular remodelling, right ventricular pressure and hypertrophy in hypoxic eNOS−/− mice

As expected, eradication of eNOS gene markedly decreased relaxant responses to acetylcholine in intrapulmonary arteries (10 µM acetylcholine inducing 19.4 ± 2.7% and 50.4 ± 4.5% relaxation in eNOS−/− and WT normoxic mice, respectively). Residual relaxation to acetylcholine in intrapulmonary arteries from eNOS−/− mice was L-NAME insensitive and likely mediated

Deletion of eNOS gene did not prevent hypoxia-induced hyper-responsiveness to phenylephrine (Figure 7A). However, following chronic hypoxia, remodelling of intrapulmonary arterioles (Figure 7B), increase in right ventricular systolic pressure (Figure 7C) and right ventricular hypertrophy (Figure 7D) were all significantly attenuated in eNOS-/- mice, compared to WT (without any significant difference in body weight between these groups).

**Discussion**

The main results of this study are the followings: (i)- in lungs, chronic hypoxia increased BH$_4$ levels, without modifying BH$_2$ levels and protein expression of GTPCH-1 and DHFR, two key enzymes regulating BH$_4$ levels; (ii)- chronic hypoxia up-regulated eNOS expression in lungs and intrapulmonary arteries, but did not decrease eNOS dimer / monomer ratio in intrapulmonary arteries; (iii)- the BH$_4$ precursor sepiapterin did not modify hypoxia-induced alterations of vasomotor responses or remodelling in intrapulmonary arteries, but it prevented increase in right ventricular systolic pressure and right ventricular hypertrophy; (iv)- eNOS gene deletion attenuated hypoxia-induced remodelling of pulmonary arterioles, increase in right ventricular systolic pressure and right ventricular hypertrophy.

Data obtained in mutant models underline a pivotal role of BH$_4$ in the pathogenesis of pulmonary hypertension [11,12]. We thus investigated BH$_4$ level in a relevant pathophysiological mouse model of pulmonary hypertension. Since previous studies [11] demonstrated that, even though right ventricles from hypoxic mice displayed elevated systolic pressure and hypertrophy following one week hypoxia, lung level of BH$_4$ remained unchanged, we determined lung BH$_4$ levels after longer exposure to hypoxia (10, 21 and 40 days). We demonstrated that chronic hypoxia, whatever its duration, does not reduce the lung content of BH$_4$, but rather increases it. The transient increase of GTPCH-1 expression (the limiting step for de novo BH$_4$ biosynthesis) in intrapulmonary arteries following 21 days of hypoxia may contribute to BH$_4$ content elevation in whole lung. However, no change of GTPCH-1 expression occurred after 10 or 40 days hypoxia, either in lungs or in intrapulmonary arteries, suggesting that increased catalytic activity of this enzyme, rather than increased expression, may be responsible for such increased BH$_4$ content.

In the absence of BH$_4$ deficiency, increased BH$_2$ levels (thus resulting in a decrease of BH$_4$/BH$_2$ ratio) is a determinant of eNOS uncoupling in intact cells [7-9]. We show here that the lung content of BH$_2$ remained unchanged at the different time of hypoxia exposure, with no changes of DHFR protein expression (the enzyme which recycles BH$_2$ into BH$_4$). Together with the increase in BH$_4$ level, the consequence is an
In accordance with previous studies [29,30], we show here that chronic hypoxia up-regulated eNOS expression (after 21 and 40 days of hypoxia in intrapulmonary arteries, and as early as 10 days and for subsequent duration of hypoxia in lungs). Thus, in lungs, time course of hypoxia-induced eNOS up-regulation and BH$_4$ increase are similar, arguing against profound modification of eNOS/BH$_4$ stoichiometry. A decrease of the eNOS dimer / monomer ratio is generally accepted as an index of biopterin-dependent eNOS uncoupling [5]. Consistently with the increase in lung BH$_4$, we show that chronic hypoxia increased, but did not decrease, eNOS dimer / monomer ratio in intrapulmonary arteries. This also argues against the role of another mechanism of eNOS dimers destabilization, biopterin-independent, such as the oxidation of the zinc-thiolate cluster of eNOS with subsequent release of zinc [31]. Altogether, these data demonstrate the absence of destabilization of eNOS dimers and biopterin-dependent eNOS uncoupling in the initiation and/or the progression of hypoxia-induced pulmonary hypertension.

The present study demonstrates that exogenous sepiapterin (a precursor of BH$_4$ via DHFR) failed to modify hypoxia-induced remodelling and alteration in vasomotor responses of...
intrapulmonary arteries. This cannot be attributed to down-regulation of DHFR, since we showed that lung and intrapulmonary arteries expression of this enzyme remains unchanged following chronic hypoxia. We show here that chronic treatment with sepiapterin partially prevented hypoxia-induced increase in right ventricular systolic pressure and right ventricular hypertrophy. This cannot be attributed to prevention of hypoxia-induced eNOS destabilisation in cardiac tissue, since we show that chronic hypoxia did not modify dimer / monomer ratio of eNOS in right ventricles. The protective effect of sepiapterin on right ventricular systolic pressure and cardiac hypertrophy may be related to local increase in BH4, which may exert direct (i.e. NOS-independent) antioxidant effects [32,33].

As recently described, sepiapterin and BH4 protect soluble guanylate cyclase against oxidative inactivation, by a mechanism unrelated to NO synthase function and not limited to endothelial cells [34]. Sepiapterin also inhibits growth factors-induced cell proliferation and migration by a NO-independent mechanism [35]. Whether these mechanisms contribute to the cardiac protective effects of sepiapterin in hypoxic mice deserves future investigations.

In this study, some experiments were performed in eNOS⁻/⁻ mice. The rationale was that some [36,37], but not all [38,39] studies, report that hypoxic eNOS⁻/⁻ mice exhibit less remodelling of small pulmonary vessels or right cardiac ventricles, compared to hypoxic WT mice. An attractive

doi: 10.1371/journal.pone.0082594.g005
hypothesis is that, in hypoxic WT mice, uncoupled eNOS generates deleterious ROS (promoting contraction and proliferation of pulmonary smooth muscle cells) rather than the vasculoprotective NO. We demonstrate here that, compared to hypoxic wild-type mice, hypoxic eNOS\(^{-/-}\) mice display similar hyper-responsiveness to phenylephrine in intrapulmonary arteries, but are partially protected against hypoxia-induced remodelling of pulmonary arterioles, increase in right ventricular systolic pressure and right ventricle hypertrophy. The conflicting data regarding the consequence of eNOS deletion in pulmonary hypertension may depend on the genetic background of the mice [36], as exacerbation of remodelling was observed in mixed C57BL6/sv129 eNOS\(^{-/-}\) mice [38,39], whereas attenuation was evidenced in C57Bl/6 eNOS\(^{-/-}\) mice, as used here and previously [36,37]. Because BH\(_4\) and/or BH\(_2\)-dependent eNOS destabilisation appears unlikely in cardiac ventricles and pulmonary vasculature from hypoxic mice, protection afforded by eNOS gene deletion might be explained by BH\(_4\) and/or BH\(_2\)-independent eNOS uncoupling in WT hypoxic mice. These include L-arginine depletion [5], accumulation of the endogenous eNOS inhibitors methylarginines [5,40], defect in heat shock protein 90 / eNOS interaction [41], S-glutathionylation of eNOS [42] or thiylradical formation on the enzyme [43]. Even though some of these mechanisms are relevant in the pathogenesis of pulmonary hypertension [41,44-47], it remains unclear whether they necessarily imply modification of the dimer / monomer ratio of eNOS, which, as demonstrated here, was not affected in the pulmonary vasculature and right ventricles from hypoxic mice. Some compensatory mechanisms may also account for protection afforded by eNOS gene deletion. These may include activation of the cyclooxygenases-derived protective factors, which occurs in pulmonary vasculature of eNOS\(^{-/-}\) mice [26] and/or activation of local atrial natriuretic peptide signalling, which prevents hypertensive cardiac hypertrophy in eNOS\(^{-/-}\) mice [48]. These hypotheses obviously deserve further investigations.

To conclude, this study demonstrates the absence of BH\(_4\)/BH\(_3\) changes and eNOS monomerisation, which may induce eNOS uncoupling during hypoxia-induced pulmonary hypertension.

**Figure 6. Effect of sepiapterin on hypoxia-induced remodeling of pulmonary arterioles, right ventricular pressure and hypertrophy.** (A) Representative pictures, and (B) quantified data of wall thickness of pulmonary arterioles in mice exposed to normoxia (NX) or in mice exposed to 21 days of hypoxia (HX 21d) which were treated or not with sepiapterin (30 mg/kg, one day before exposure to hypoxia and every other day during hypoxia). hypertension. Thus, even though eNOS gene deletion and sepiapterin treatment exert some protective effects, this appears unrelated to bipterin-dependent eNOS dimer destabilisation and uncoupling within pulmonary vasculature of hypoxic wild-type mice. Since right ventricular pressure and hypertrophy are clinical endpoints of pulmonary hypertension, the mechanisms of the cardioprotection afforded by eNOS gene deletion or sepiapterin treatment deserve to be further investigated.
