Numerical study of non-Darcy hybrid nanofluid flow with the effect of heat source and hall current over a slender extending sheet

Zehba Raizah1, Hussam Alrabaiah2,3, Muhammad Bilal4, Prem Junsawang5,6,7 & Ahmed M. Galal6,7

The current evaluation described the flow features of Darcy Forchheimer hybrid nanoliquid across a slender permeable stretching surface. The consequences of magnetic fields, second order exothermic reaction, Hall current and heat absorption and generation are all accounted to the fluid flow. In the working fluid, silicon dioxide (SiO2) and titanium dioxide (TiO2) nano particulates are dispersed to prepare the hybrid nanoliquid. TiO2 and SiO2 NPs are used for around 100 years in a vast number of diverse products. The modeled has been designed as a nonlinear set of PDEs, Which are degraded to the dimensionless system of ODEs by using the similarity transformation. The reduced set of nonlinear ODEs has been numerically estimated through bvp4c package. The outcomes are tested for validity and consistency purpose with the published report and the ND solve technique. It has been noted that the energy curve lessens with the influence of thermodiffusion, Brownian motion and rising number of nanoparticles, while boosts with the result of magnetic field. Furthermore, the concentration outline of hybrid nanoliquid improves with the upshot of chemical reaction.

Abbreviations

- n: Power index
- \( U_0 \): Reference velocity
- \( m \): Hall current
- \( K^* \): Permeability factor
- 2D: Two-dimension
- \( F \): Non-uniform inertia factor
- \( T \): Temperature
- \( Nt \): Thermodiffusion
- \( Pr \): Prandtl number
- \( \mu_{hnf} \): Viscosity
- \( (\rho C_P)_{hnf} \): Thermal capacity
- \( k_{hnf} \): Thermal conductivity
- \( \phi_1 = \phi_{SiO_2} \): Nanoparticles volume friction
- \( C_2H_6O_2 \): Ethyne glycol
- \( (u, v, w) \): Velocity component
- \( A \): Stretching constant
- \( U_w \): Stretching velocity

The analysis of fluid flow over a slendering surface has frequent implementations in various fields, containing manufacture of glass, aerodynamic, polymer industry, firmness of plastic slips and metal tubulars. Gul et al. examined and evaluated the proficiency of a hybrid nanofluid along an increasing sheet. It was discovered that the magnetism influence altered the instability of liquid. Bilal et al. employed the PCM methodology to imitate the movement of nanoliquids through a stretchable material with the effects of suction and injection. The physical and chemical properties of nanofluid flow passing through permeable stretching was documented by Safwa et al. Moreover, Hussain et al. reported the energy conversions of MHD nanoliquid flow along an elongating surface. Shuaib et al. described the ferrofluid flow along with the characteristics of energy conveyance through spinning sheet. Hussain et al. assessed the energy transport through nanoliquid flow over an extending cylinder. Uddin et al. analysed the energy transmission through water-based nanoliquid across an expanding surface. Rasool et al. documented the nanoliquid flow across a contracting surface. Ahmad et al. assessed nanoliquid fluid across a slender stretching sheet.

Hybrid nanoliquid has greater thermal efficiency and mostly utilized in industry for cooling purposes. Hybrid nanofluid work in solar energy, energy transition, air conditioners, generators, the vehicle sector, radioactive systems, electrical coolers, ships, biotechnology and transmitters. TiO₂ and SiO₂ have non-toxic, non-reactive characteristics and absorb UV rays used for skin cancer, drug delivery, recording devices and solar cells. Tariq et al. conducted an experimentally assessed the density, optical characteristics and surface tension of SiO₂-containing nanoliquids based on ethylene glycol. Using the bvp4c software, Bhatti et al. provided a detailed discussion of SiO2 and carbon nanocrystals over an elastic substrate. Ahmed et al. scrutinized the nanoliquid flow and energy conveyance through Al₂O₃ and TiO₂ nps based nanoliquid, to augments the thermal efficiency of base solvent, such as thermal diffusivity and heat transport coefficient. Khashi’ie et al. examined and evaluated the proficiency of a hybrid nanoliquid flow over an elongating sheet. Alwawi et al. addressed the impact of magnetism on nanofluid streaming in the scenario of coupled convection across a circular cylinder. The findings show that increasing the coupled convection factor's value improves the Nusselt number, velocity, skin friction and rotational velocity while reducing the thermal contour's trends. Abbasi et al. comparatively reported the thermal assessment of three distinct sorts of nano particulates, including TiO₂, SiO₂ and aluminum oxide through curved sheet. Khashi’ie et al. used Cu-Al₂O₃ hybrid nanoparticles to study the Blasius flow across a rotating plate. De and Mondal investigated the combined influence of Soret-Dufour interactions in a nanoliquid flow. Recently, a number of investigators have described on the evaluation of hybrid nanoliquid flow over distinct configuration.

Hall current can be detected if the fluid density is small, or the magnetic flux density amplitude is strong. In many practical operations that call for an intense electric affect and smaller atomic concentration, hall effects should not be undervalued. Electron transport, where electrons move more quickly than ions, is what results in isotropic conductivity. Ohm's law needs to be revised for the purposes to consider the Hall effect. It has several applications in Hall activators, circuits, pumps, electric inverters, turbines and other equipment. Nanoliquid flow with the upshot of Hall current and magnetic effect has drawn the attention of scientists. Using an extended sheet, Khan and Nadeem examined a spinning Maxwell nanoliquid flow with a magnetism, Hall current and kinetic energy. An asymmetrical reactive nanoliquid flow induced by a magnetization revolving plate and the Hall impact is described by Acharya et al., along with the flow dynamics and energy variations. They found that the energy transference was improved by 84.61% by nanocomposites. The Hall effect in nanofluid flow has recently been the subject of numerous investigations.

The purpose of the current assessment is to study the flow features of Darcy Forchhammer hybrid nanoliquid across a slender permeable stretching surface. The consequences of magnetic fields, second order exothermic reaction, Hall current and heat absorption and generation are all accounted to the fluid flow. In the working fluid, SiO₂ and TiO₂ nano particulates are dispersed to prepare the hybrid nanoliquid. The modeled has been designed as a nonlinear set of PDEs. Which are transmute to the dimensionless system of ODEs by using the similarity replacement. The reduced set of nonlinear ODEs has been numerically estimated through bvp4c package.

### Mathematical framework

We assumed a steady 2D MHD hybrid nanoliquid flow through impermeable slendering substrate. The surface is stretching with velocity \( U_p(x) = (x + b)^n U_0 \), as described in Fig. 1, where \( n \) is the power index. The sheet irregularity is assumed as \( y = A(x + b)^{1/2} \), \( A \) is the stretching constant. The Hall and magnetic effect are
employed for flow motion in $y$-direction. Heat source, Brownian motion, thermo-diffusion and chemical reactions are all observed in current analysis.

The basic equations responsible for the fluid flow are characterized as:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0,$$

$$\rho_{nf} \left( \frac{u \partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = \mu_{nf} \frac{\partial^2 u}{\partial y^2} - \frac{\sigma_{nf}}{1 + m^2} B^2(x)(u + mw) - \frac{v_{hf} u}{K^*} - 1 \rho_{hf} F u^2,$$

$$\rho_{nf} \left( \frac{u \partial w}{\partial x} + v \frac{\partial w}{\partial y} \right) = \mu_{nf} \frac{\partial^2 w}{\partial y^2} - \frac{\sigma_{nf}}{1 + m^2} B^2(x)(mu - w) - \frac{v_{hf} w}{K^*} - 1 \rho_{hf} F w^2,$$

$$\left( \frac{\partial T}{\partial x} + \frac{\partial T}{\partial y} \right) = \frac{k_{nf}}{(\rho C_p)_{nf}} \left( \frac{\partial^2 T}{\partial y^2} \right) + \left( \frac{D_B}{T_{\infty}} \frac{\partial^2 C}{\partial y^2} \right) + \frac{Q_0 (T - T_{\infty})}{\rho C_p},$$

$$\left( \frac{\partial C}{\partial x} + \frac{\partial C}{\partial y} \right) = D_B \left( \frac{\partial^2 C}{\partial y^2} \right) + \frac{D_T}{T_{\infty}} \frac{\partial^2 T}{\partial y^2} - Kc^2 (C - C_{\infty}),$$

here, $m = \tau_{we}$ is the Hall current, $Kc^2$, $Q_0$, $K^*$ and $F = C_B / rK^*1/2$ are the chemical reaction rate, heat source, permeability factor and non-uniform inertia factor respectively.

The initial and boundary conditions are:

$$u = U_w(x) = U_0 (x + b)^n, \quad v = 0, \quad w = 0, \quad \frac{\partial C}{\partial y} + \frac{D_T}{T_{\infty}} \frac{\partial T}{\partial y} = 0, \quad T = T_w \text{ at } y = A(x + b)^{1/n},$$

$$u \to 0, \quad T \to T_{\infty}, \quad w \to 0, \quad C \to C_{\infty} \text{ as } y \to \infty.$$
\begin{align}
\eta &= y \sqrt{\frac{n+1}{2} \frac{U_0}{\nu f} (x+b)^{m-1}} ,
\psi &= \sqrt{\frac{2}{n+1} \nu y U_0 (x+b)^{m+1}} f(\eta),
\varphi(\eta) &= \frac{C - C_\infty}{C_w - C_\infty}, \\
w &= U_0 (x+b)^{m} h(\eta), 
\theta(\eta) &= \frac{T - T_\infty}{T_w - T_\infty}.
\end{align}

By merging Eq. (7) in Eqs. (1)–(6), we get:

\begin{align}
f'''' + \frac{\partial}{\partial \eta} \left( \left( f'''' - \frac{2n}{n+1} Pr f'' \right) \right) - \frac{\partial}{\partial \eta} \left( \frac{2M}{(n+1)(1+m^2)} \right) f'' + \lambda mg &= 0, \\
g'''' + \frac{\partial}{\partial \eta} \left( \left( g'''' - \frac{2n}{n+1} Pr gf'' \right) \right) - \frac{\partial}{\partial \eta} \left( \frac{2M}{(n+1)(1+m^2)} \right) mf'' - \lambda g &= 0, \\
\theta'' + Pr \frac{\partial}{\partial \eta} \left( f(\theta' + Nb \psi' + Nt \theta'') + Q_t \theta \right) &= 0, \\
\psi'' + \frac{Nt}{Nb} \theta'' + Lef \psi' - K_{r} \psi &= 0.
\end{align}

here, \( \theta_1 = \frac{\rho_{nf}}{\rho_f}, \theta_2 = \frac{\mu_{nf}}{\mu_f}, \theta_3 = \frac{\tau_{nf}}{\tau_f}, \theta_4 = \frac{(\rho C_p)_nf}{(\rho C_p)_f}, \theta_5 = \frac{k_{nf}}{k_f} \).

The conditions for system of ODEs are:

\begin{align}
f(\eta) &= \eta \left( \frac{1-n}{1+n} \right), \quad Nb \psi' + Nt \theta'(\eta) = 0, \quad f'(\eta) = 1, \quad g(\eta) = 0, \quad \theta(\eta) = 1 \\
f''' \to 0, \quad g \to 0, \quad \theta \to 0, \quad \psi \to 0 \text{ as } \eta \to \infty
\end{align}

here, the \( M, \lambda, Pr, Nt, Nb, Fr, Q_t, Le, Gr, \delta, Gc \) and \( K_r \) is mathematically expressed as:

\begin{align}
M &= \frac{R^2 \sigma_f \rho_f}{\rho_f T_\infty},
Pr &= \frac{\mu_f (\rho C_p)_f}{\rho_f T_\infty},
\lambda &= \frac{\nu}{k_f},
Nt &= \frac{\tau D_T (T_w - T_\infty)}{T_f T_\infty},
Fr &= \frac{C_b}{K_1 T},
Nb &= \frac{\tau D_B C_\infty}{T_f},
Q_t &= \frac{x Q_0}{\rho C_p},
Le &= \frac{\nu}{D_B},
Gr &= \frac{g \beta_f (T_w - T_\infty)n}{U_n^2},
Gc &= \frac{g \beta_f (C_w - C_\infty)n}{U_n^2},
K_r &= \frac{K_c^2}{b}.
\end{align}

The physical interest quantities are:

\begin{align}
C_{f_1} &= \frac{2 \tau w_1}{U_n^2, \rho_f},
C_{f_2} &= \frac{\tau w_2}{U_n^2, \rho_f},
Nt &= \frac{q_w (x+b)}{(T_w - T_\infty)},
Sh &= \frac{j_w (x+b)}{(C_w - C_\infty)D_B}.
\end{align}

where,

\begin{align}
\tau w_1 &= \mu_{nf} \left( \frac{\partial u}{\partial y} \right)_{y=A(x+b)} \left( \frac{1}{2} \right),
\tau w_2 &= \mu_{nf} \left( \frac{\partial v}{\partial y} \right)_{y=A(x+b)} \left( \frac{1}{2} \right),
q_w &= -k_{nf} \left( \frac{\partial T}{\partial z} \right)_{y=A(x+b)} \left( \frac{1}{2} \right) \left( \frac{1}{2} \right),
\end{align}

The dimensionless structure of Eq. (14) is:

\begin{align}
C_{f_1} &= \sqrt{Re_x} C_{f_1} = (1 - \phi_1)^{-2.5} \left( 1 - \phi_2 \right)^{-2.5} \sqrt{2(n+1)} f''(0), \\
C_{f_2} &= \sqrt{Re_x} C_{f_2} = (1 - \phi_1)^{-2.5} \left( 1 - \phi_2 \right)^{-2.5} \sqrt{2(n+1)} g'(0), \\
Ntu &= \frac{Nu}{\sqrt{Re_x}} = -k_{nf} \frac{k_f}{k_f} \left( \frac{n+1}{2} \right) \left( \frac{1}{2} \right) \theta'(0),
Sh &= \frac{Sh}{\sqrt{Re_x}} = -\sqrt{\frac{n+1}{2}} \psi'(0).
\end{align}

\textbf{Numerical methodology}

The system of Eqs. (8)–(12) are simplified to 1st order set of ODEs and solved through bvp4c package as\textsuperscript{42,45}

\begin{align}
\xi_1 &= f(\eta), \quad \xi_2 = f''(\eta), \quad \xi_3 = g'(\eta), \quad \xi_5 = \theta'(\eta), \quad \xi_6 = \psi'(\eta), \\
\xi_7 &= \theta(\eta), \quad \xi_8 = \psi(\eta).
\end{align}

By putting (17) in (8–12), we get:
\[
\xi_3^\prime + \frac{\partial}{\partial z} \left( \frac{\xi_1}{\xi_3^2} - \frac{2n}{n+1} \xi_3^\prime \xi_2^\prime \right) - \frac{\partial}{\partial t} \left( \frac{2M}{(n+1)(1+m^2)} \right) \xi_2 + \lambda m \xi_4 \xi_5 = 0, \tag{18}
\]

\[
\xi_5^\prime + \frac{\partial}{\partial z} \left( \frac{\xi_1}{n+1} \xi_5^\prime - \frac{2n}{n+1} \xi_4^\prime \xi_2^\prime \right) - \frac{\partial}{\partial t} \left( \frac{2M}{(n+1)(1+m^2)} \right) m \xi_2 - \lambda \xi_4 \xi_5 = 0, \tag{19}
\]

\[
\xi_7 + Pr \frac{\partial}{\partial z} \left( \frac{\xi_1}{n+1} \xi_7 + Nb \xi_5^\prime \xi_7 + Nt \xi_5^\prime \xi_8 \right) + Q_1 \xi_6 = 0, \tag{20}
\]

\[
\xi_8^\prime + \frac{Nt}{Nb} \xi_8^\prime + Le \xi_1 \xi_9 - Kr^2 \xi_8 = 0. \tag{21}
\]

The transform conditions are:

\[
\xi_1(\eta) = \frac{1}{1+\frac{n}{1+n}} \left( \frac{1-n}{1+n} \right), \quad Nb \xi_9(\eta) + Nt \xi_7(\eta) = 0, \quad \xi_2(\eta) = 1, \quad \xi_4(\eta) = 0, \quad \xi_6 = 1 \tag{22}
\]

**Result and discussion**

This segment estimates the exhibition of velocity, energy and concentration outlines versus interest constraints and explain the physics behind each table and figures. The dimensionless set of ODEs (Eqs. (18)–(22)) are solved through bvp4c package.

**Velocity curve** \( f'(\eta) \). Figure 2a–d communicates the demonstration of velocity \( f'(\eta) \) curve versus \( m, \delta, n, \phi_1, \phi_3, Gc \) and \( Gr \) respectively. Figure 2a,b revealed that flow velocity amplifies with the outcome of \( m \) and diminishes with the impact of \( \delta \). Figure 2c,d exhibits that flow velocity augments with the influence of \( n \) and lessens with the impact of \( \phi_1, \phi_3 \) respectively. The result of \( n \) decreases the shear stress of surface, as a result the fluid velocity improves with action of \( n \). The developing amount of TiO\(_2\) + SiO\(_2\) nps grows the fluid viscosity, which triggers the retardation effect. Figure 2e,f emphasized that velocity outline boosts with the increment of thermal and mass Grashop number. The extending velocity of surface drops with the upshot of \( Gc \) and \( Gr \) which triggers the rises in the velocity outline.

Figure 3a–d demonstrated the comportment of \( g(\eta) \) outline versus parameter \( m, n, \delta, Fr \) and \( M \). Figure 3a–b revealed that the flow velocity considerably upsurges with the change of \( m \) and \( n \). While declines with the addition of \( \delta \) and \( M \). The magnetic upshot causes Lorentz effect, which prevents the flow moment, so the velocity profile drops. Figure 3e presents that the consequences of \( Fr \) pointedly de accelerates the velocity field in the radial direction.

**Energy curve** \( \theta(\eta) \). Figure 4a–d demonstrates the arrangement of temperature \( \theta(\eta) \) curve against \( \delta, m, n \) and \( Q \). Figure 4a,b describes that the energy \( \theta(\eta) \) outline enlarged with the action of \( m \) and reduces under the upshot of \( \delta \). Hall current result also creates confrontation, which uplifts the energy contour as perceived in Fig. 4a. Figure 4c,d represent the significances of \( n \) and \( Q \), that their effects augment the energy profile of SiO\(_2\) + TiO\(_2\)/C\(_x\)H\(_y\)O\(_z\)/H\(_2\)O hybrid nanoliquid. The consequence of \( Q \) term operational as a energy mediator for the nanoliquid, which directly effects the temperature outline \( \theta(\eta) \).

Figure 5a–d emphasized the appearance of heat \( \theta(\eta) \) contour relative to \( Nb, Nt, \phi_1, \phi_1, \phi_3 \) and \( M \). Figure 5a–c designated that fluid energy curve drops with the effect of \( Nb, Nt \) and \( \phi_1 \) while enhances with the influence of magnetic field. The mounting number of nano particulates intensifies the flow velocity as well as the heat capacity of the ordinary fluid, which fallbacks such scenario. As earlier deliberated that the repellant strength created by the magnetic field, absolutely effects the energy curve \( \theta(\eta) \).

**Mass profile** \( \psi(\eta) \). Figure 6a–c defined the exhibition of concentration \( \psi(\eta) \) contour versus \( m, \delta, n \) and \( Kr \). The concentration conversion of hybrid nanoliquid intensify with the upshot of \( m \) and declines with the impact of \( \delta \) as exhibited in Fig. 6a,b. Figure 6c,d described that the upshot of \( Kr \) and \( n \) both augment the mass transport. The factor \( Kr \) boosts the kinetic force within the nanofluid, which results in the quick communication of concentration \( \psi(\eta) \).

Figure 7 emphasized the relative examination of nanofluid (SiO\(_2\) + TiO\(_2\)) and hybrid nanoliquid (SiO\(_2\) + TiO\(_2\)/C\(_x\)H\(_y\)O\(_z\)/H\(_2\)O) for the energy and the velocity outline. Tables 1 and 2 represent the tentative values and mathematical model for SiO\(_2\), TiO\(_2\) and base fluid. Table 3 described the numerical calculation of the present outcomes with the ND solver approach, to approve the authenticity of the results. Table 4 discovered the arithmetic evaluations of SiO\(_2\)+TiO\(_2\)/C\(_x\)H\(_y\)O\(_z\)/H\(_2\)O hybrid nanoliquid for \( \zeta_{fr}, \zeta_{fr}, Nu, \text{ and } Sh \). It is identified that the upshot of \( m \) augments the energy interaction rate and drag force.
**Conclusion**

We have examined the flow features of hybrid nanoliquid through a slender stretching surface. The consequences of second order exothermic reaction, heat source, Hall current and magnetic fields are all also described. The modeled equations are assessed by using the numerical approach bvp4c package. The important conclusions are:

- The $f'(\eta)$ outline augments with the outcome of $n$ and $m$ and while reduces with the rising quantity of nano particulates $\phi_1$, $\phi_2$ and parameter $\delta$.
- The velocity $g(\eta)$ curve substantially upsurges with effect of $n$ and $m$. While decreases with the effect of $\delta$ and $M$.

*Figure 2.* The exposition of velocity $f'(\eta)$ curve versus constraints $m$, $\delta$, $n$, $\phi_1$, $\phi_2$, $Gc$ and $Gr$ respectively.
• The energy $\theta(\eta)$ curve is enhances with the variation of $m$ and diminishes with the $\delta$.
• The energy $\theta(\eta)$ contour diminish with the influence of $Nb$, $Nt$ and $\phi_1$, $\phi_2$, while boosts with the outcome of magnetic effect.
• The concentration $\phi(\eta)$ outline of hybrid nanoliquid improves with the upshot of $Kr$ and $n$.
• The current model may be expanded to other type of fluid and can be used different chemical composition nanoparticles in the base fluid for desire output. Furthermore, different numerical, analytical and fractional methods can also be used to solve such problems.
