ABSTRACT

Solar, atmospheric and reactor neutrino experiments established that neutrinos are massive. It is quite natural then to consider neutrinos as candidate particles for explaining the dark matter in halos around galaxies. We study the gravitational clustering of these neutrinos within a model of a massive core and a surrounding spherical neutrino halo. The neutrinos form a degenerate Fermi gas and a loaded polytropic equation is established. We solve the equation and we obtain the neutrino density in a galaxy, the size of the galaxy and the galactic rotational curves. The available data favor a neutrino with a mass around 10 eV. The consequent cosmological implications are examined.

Keywords: Neutrinos; Neutrino Mass; Gravitational Clustering; Dark Matter; Polytrope Equation

Solar, atmospheric, reactor and accelerator neutrinos have provided compelling evidence for the existence of neutrino oscillations, implying non-zero neutrino masses [1,2]. Solar neutrino oscillations indicate a mass squared difference \( \Delta m^2_{\text{sol}} = 6 \times 10^{-5} \text{ eV}^2 \) while atmospheric neutrino oscillations suggest \( \Delta m^2_{\text{atm}} = 2 \times 10^{-3} \text{ eV}^2 \). Further, attributing the LSND anomaly to neutrino oscillations implies the existence of a fourth neutrino, a sterile one, with a mass above 1 eV [3]. Cosmology offers further insights on the neutrino mass scales [4-7]. It is inevitable that neutrinos have participated in gravitational clustering around massive galaxies, constituting part of the dark matter. Our purpose is to investigate the neutrino clustering effect, obtaining information on the cosmological presence of massive neutrinos.

The universe today exhibits structure on many scales. Galaxies range in mass, with most bright galaxies having masses of \( 10^{10}-10^{12} M_\odot \). The sizes and distributions of present-day galaxies reflect the spectrum of initial density fluctuations, seeded by random motion or cosmic strings [8]. We expect that each galaxy attracts the cosmological neutrinos in its neighbourhood, creating a neutrino halo of an average mass \( 10^{31} \text{ eV} \). Our idealized galaxy consists of a spherical massive core (of a mass \( M_c = \sigma M_\odot \) and a radius \( r_c \) of few Kpc) surrounded by a spherical neutrino halo. Hydrostatic equilibrium prevails

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dP}{dr} \right) = -4\pi GmN
\]

where \( N(r) \) is the neutrino density, \( m \) is the neutrino mass and \( P(r) \) is the pressure of the neutrino gas. Considering that the neutrinos form a degenerate Fermi gas we obtain a polytrope equation

\[
P = \left( \frac{3}{4 g\pi} \right)^{2/3} \frac{h^2}{5m} N^{5/3}
\]

with the degeneracy factor \( g = 2 \) (left-handed neutrinos and right-handed antineutrinos). Equations (1) and (2) lead to

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{1}{N^{1/3}} \frac{dN}{dr} \right) = -\gamma N
\]

\[\gamma = m^5 \left( 3g^2 \right)^{1/3} \left( 4\pi \right)^{5/3} G/h^2 \]

Introducing the (dimensionless) variables \( p \) and \( x \) through

\[
N(r) = \frac{g}{6\pi^2} \left( \frac{2m^2}{h^2} \right)^{3/2} \left( \frac{G\sigma M_\odot P}{r} \right)^{3/2}
\]

\[r = q x\]

\[q = \left( \frac{3\pi h^3}{4\sqrt{2}g m^4 G^{3/2} M_\odot^{1/2} \sigma^{3/2}} \right)^{2/3}\]

Equation (3) becomes

\[
\frac{dp}{dx^2} = -\frac{p^{3/2}}{\sqrt{x}}
\]

The variable \( p \) is related to the gravitational potential \( V(r) \) through
\[ p = \frac{r(V_0 - V)}{GM_\nu} \]  

\( V_0 \) is the gravitational potential at the outer part of the galaxy, where the density vanishes. Indeed the numerical solution of Equation (8) always provides a finite value at \( x_0 \), where \( p(x_0) = 0 \). The radius \( R \) of the galaxy is then \( R = q x_0 \) (Equation (6)). The total mass of the galaxy \( (M = M_\nu + M_\nu) \) is related to the derivative of \( p(x) \) at \( x_0 \) by

\[ -\left( x \frac{dp}{dx} \right)_{x=x_0} = \frac{M_\nu + M_\nu}{M_\nu} \]

At \( r = r_c \) the boundary condition is

\[ p(x = x_c) = 1.0 \]

Equation (8) together with the boundary conditions (10) and (11), represents a loaded polytrope [9-13]. Similar mathematical structures appear in the study of a galactic nucleus, a neutron star, or in the Thomas-Fermi description of an atom.

We solved numerically Equation (8), using the boundary condition of Equation (11) and an arbitrary positive value for the derivative of \( p(x) \) at \( x = x_c \). The numerical solution provides a function \( p(x) \) which rises up to a maximum, then decreases until it vanishes at some point \( x_0 \) \( p(x_0) = 0 \). We evaluated also the derivative of \( p(x) \) in the neighbourhood of \( x_0 \) and subsequently the left-hand side of Equation (10), thus determining the ratio \( M_\nu / M_\nu \). To obtain the desired ratio \( M_\nu / M_\nu \), we repeat the numerical evaluation with a different value for the derivative of \( p(x) \) at \( x_c \), until we achieve the predetermined \( M_\nu / M_\nu \) ratio. The numerical study revealed the following essential features of the loaded polytrope:

1) The precise value of \( x_0 \) is largely independent of the ratio \( M_\nu / M_\nu \). More massive neutrino halos provide larger values for the maximum of \( p(x) \), but all neutrino densities vanish in the vicinity of \( x_0 = 2.0 \). Thus the radius \( R \) of the galaxy is set up by the constant \( q \) (Equations (6) and (7)).

2) The scale \( q \), Equation (7), is very sensitive to the mass of neutrino \( m \). By increasing the mass of the neutrino by a factor 3, the size of the galaxy is reduced by a factor 19. The overall data are well reproduced with a neutrino mass at 10 eV.

3) Equation (7) gives then the numerical expression

\[ q = \frac{1.7}{\sigma^0} \times 10^5 \text{Kpc} \]

For a massive core \( M_\nu = 10^{11} M_\odot \), we obtain \( q = 36 \text{Kpc} \) and therefore \( R = 70 \text{Kpc} \), in agreement with the data for the size of massive galaxies [14]. It is impressive that a scale \( q \) which is expressed in terms of fundamental constants, such as the Planck constant, the neutrino mass and the Newton constant, reproduces accurately the galactic sizes.

4) Through Equation (5) we obtain back the neutrino density \( N(r) \). We observe that at small distances, \( N(r) \) behaves as

\[ N(r) \sim \frac{1}{r^{3/2}} \quad \text{at small } r \]

while the neutrino density diverges as \( r \to 0 \), the total neutrino mass \( M_\nu \) remains finite.

Figure 1 shows the neutrino density as a function of the rescaled distance \( x \). The upper curve corresponds to \( M_\nu = 10^{11} M_\odot \), \( M_\nu = 10 M_\odot \), while the lower curve corresponds to \( M_\nu = 10^{11} M_\odot \), \( M_\nu = M_\odot \). Near the galactic core, the neutrino density is high as \( 10^7 \) neutrinos/cm\(^3\), and over the uniform density of the big-bang cosmology, the gravitational clustering provides locally an increase by a factor \( 10^5 \).

The spherical neutrino halo up to a rescaled distance \( x \), gives a mass \( M_\nu(x) \), where

\[ M_\nu(x) = \sigma M_\odot \left[ \int_0^{1/2} \left[ p(y) \right]^{1/2} \, dy \right] \]

Obviously \( M_\nu = M_\nu(x_0) \). The galactic rotational velocity, due to the neutrino halo, is then

\[ u = \left( \frac{GM_\nu(r)}{r} \right)^{1/2} \]

Figure 2 shows the galactic rotation curves (upper
The few eV mass scale for the sterile neutrino, that our study suggests, fits nicely with the findings of the reactor mass sterile neutrino is rather unclear. The standard cosmology for a few eV and short-based neutrino oscillation experiments [3]. On another direction, there is strong evidence for the existence of distinct mass scales for the neutrinos, sub-eV, eV and keV, indicates the complexity of neutrino physics. Clearly we need further experimental information and novel theoretical insights to decode the hidden dynamics.

In summary we presented a simplified model for the gravitational clustering of massive neutrinos in the galaxies. There is no adjustable parameter in our analysis and despite its simplicity the overall features of galactic dynamics are reproduced.
