Abstract

It has been shown that the anomalies observed in \( \bar{B} \to D^{(*)}\tau \bar{\nu}_\tau \) and \( \bar{B} \to K \ell^+ \ell^- \) decays can be resolved by adding a single scalar or vector leptoquark to the Standard Model, while constraints from other precision measurements in the flavour sector can be satisfied without fine-tuning. To further explore these two interesting scenarios, in this paper, we study their effects in the semi-leptonic \( \Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau \) decay. Using the best-fit solutions for the operator coefficients allowed by the current data of mesonic decays, we find that (i) the two scenarios give the similar amounts of enhancements to the branching fraction \( B(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau) \) and the ratio \( R_{\Lambda_c} = B(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)/B(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell) \), (ii) the two best-fit solutions in each of the two scenarios are also indistinguishable from each other, (iii) both scenarios give nearly the same predictions as the Standard Model for the longitudinal polarizations of \( \Lambda_c \) and \( \tau \) as well as the lepton-side forward-backward asymmetry. With future measurements of these observables in \( \Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau \) decay at the LHCb, the two leptoquark scenarios could be further tested, and even differentiated from the other NP explanations to the \( R_{D^{(*)}} \) anomalies.

1 Introduction

While no direct evidences for physics beyond the Standard Model (SM) have been found at the LHC so far, there are some interesting indirect hints for New Physics (NP) in the flavour sector \cite{1–3}. It is particularly interesting to note that intriguing effects of lepton favour universality violation (LFUV) have been observed in rare $B$-meson decays. To be more specific, the ratios of charged-current decays, $R_D = \frac{\mathcal{B}(\bar{B} \to D\tau \bar{\nu}_\tau)}{\mathcal{B}(\bar{B} \to D\ell \bar{\nu}_\ell)}$ and $R_D^* = \frac{\mathcal{B}(\bar{B} \to D^*\tau \bar{\nu}_\tau)}{\mathcal{B}(\bar{B} \to D^*\ell \bar{\nu}_\ell)}$, with $\ell = e, \mu$, have been measured by the BaBar \cite{4, 5}, Belle \cite{6–8} and LHCb \cite{9} Collaborations. The latest averages by the Heavy Flavor Average Groups (HFAG) \cite{10},

$$R_D^{\exp} = 0.397 \pm 0.040 \text{(stat.)} \pm 0.028 \text{(syst.)}, \quad R_D^{\exp} = 0.316 \pm 0.016 \text{(stat.)} \pm 0.010 \text{(syst.)},$$

(1.1)

exceed the SM predictions,

$$R_D^{\text{SM}} = 0.300 \pm 0.008 \text{ \cite{11},} \quad R_D^{\text{SM}} = 0.252 \pm 0.003 \text{ \cite{12}},$$

(1.2)

by 1.9\sigma and 3.3\sigma, respectively. Once the measurement correlations between $R_D$ and $R_D^*$ are taken into account, the deviation will be at 4.0\sigma level. Another hint of LFUV has also been reported in the $b \to s\ell^+\ell^-$ process by the LHCb experiment \cite{13}:

$$R_K^{\exp} = \frac{\Gamma(B^+ \to K^+\mu^+\mu^-)}{\Gamma(B^+ \to K^+e^+e^-)} \bigg|_{q^2 \in [1,6]\text{GeV}^2} = 0.745_{-0.074}^{+0.090} \text{(stat.)} \pm 0.036 \text{(syst.)},$$

(1.3)

which is about 2.6\sigma lower than the corresponding SM prediction $R_K^{\text{SM}} = 1.00 \pm 0.03$ \cite{14, 15}.

The observed $R_D^{(*)}$ and $R_K$ anomalies, if confirmed with future more precise data, would be clear signs for NP beyond the SM, and have already inspired lots of studies; for a recent review, the readers are referred to Refs. \cite{1–3} and references therein. Here we are interested in the possible NP solutions with a single scalar or vector leptoquark (LQ) scenario \cite{16, 17}. In Ref. \cite{16}, it has been shown that the anomalies $R_D^{(*)}$, $R_K$ and $(g - 2)_\mu$ could be addressed by adding to the SM just one TeV-scale scalar LQ transforming as $(3, 1, -\frac{2}{3})$ under the SM gauge group. On the other hand, as shown in Ref. \cite{17}, the $R_D^{(*)}$, $R_K$ and the angular observable $P'_5$ in $B \to K^*\mu^+\mu^-$ decay could be explained by just one vector LQ transforming as $(3, 3, \frac{2}{3})$ under the SM gauge group. Under the constraints from both the ratios $R_D^{(*)}$ and the $q^2$ spectra
of $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_\tau$ decays provided by the BaBar [5] and Belle [6, 7] Collaborations, four best-fit solutions are found for the operator coefficients induced by the scalar LQ [18], two of which are, however, already excluded by the purely leptonic $B^-_c \rightarrow \tau^-\bar{\nu}_\tau$ decay [19]. At the same time, two best-fit solutions are also found for the operator coefficients induced by the vector LQ [18].

To further explore the two interesting LQ scenarios, in this paper, we shall study their effects in the semi-leptonic $\Lambda_b \rightarrow \Lambda_c\tau\bar{\nu}_\tau$ decay, which is induced by the same quark-level transition as the $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_\tau$ decays. While the $\Lambda_b$ baryons are not produced at an $e^+e^-$ B-factory, they account for about 20% of the $b$-hadrons produced at the LHC [20]. Remarkably, the produced number of $\Lambda_b$ baryons is comparable to that of $B_u$ or $B_d$ mesons, and is significantly higher than the one of $B_s$ mesons [20, 21]. Due to the spin-half nature of $\Lambda_b$, its decay may provide complementary information compared to the corresponding mesonic one. Motivated by the $R_{D^{(*)}}$ anomalies, the semi-leptonic $\Lambda_b \rightarrow \Lambda_c\ell\bar{\nu}_\ell$ decay has been studies recently in Refs. [22–27].

In this paper, besides the total and differential branching fractions, we shall also discuss the ratio $R_{\Lambda_c} = \frac{B(\Lambda_b \rightarrow \Lambda_c\tau\bar{\nu}_\tau)}{B(\Lambda_b \rightarrow \Lambda_c\ell\bar{\nu}_\ell)}$, the longitudinal polarizations of $\Lambda_c$ and $\tau$, as well as the lepton-side forward-backward asymmetry. For the $\Lambda_b \rightarrow \Lambda_c$ transition form factors, we use the results both from QCD sum rules [28], which satisfy the heavy quark effective theory (HQET) relations [29–31], and from the latest lattice calculations [25]. Using the best-fit solutions for the operator coefficients allowed by the current data of mesonic decays, we find that the two scenarios give the similar amounts of enhancements relative to the SM predictions for the branching fraction $B(\Lambda_b \rightarrow \Lambda_c\tau\bar{\nu}_\tau)$ and the ratio $R_{\Lambda_c}$, and the two best-fit solutions in each of the two scenarios are also indistinguishable from each other based only on these two observables. On the other hand, both of these two scenarios give nearly the same predictions as the SM for the longitudinal polarizations of $\Lambda_c$ and $\tau$ as well as the lepton forward-backward asymmetry. With future precise measurements of these observables at the LHCb, the two scenarios could be further tested and even differentiated from the other explanations to the $R_{D^{(*)}}$ anomalies [18, 32–87].

This paper is organized as follows: In section 2, we recapitulate briefly both the scalar and vector LQ scenarios [16, 17]. In section 3, we calculate the helicity amplitudes and list the relevant physical observables for the semi-leptonic $\Lambda_b \rightarrow \Lambda_c\ell\bar{\nu}_\ell$ decays. In section 4, the

\footnote{There are currently only the lattice results for the (axial-)vector form factors [25]. For the (pseudo-)tensor form factors, since there are no lattice results yet, we still use the HQET relations to relate them to the corresponding (axial-)vector ones.}
scalar and vector LQ effects on the branching fraction $\mathcal{B}(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)$, the ratio $R_{\Lambda_c}$, the $\Lambda_c$ and $\tau$ longitudinal polarizations, as well as the lepton-side forward-backward asymmetry are discussed. We finally conclude in section 5. The $\Lambda_b \to \Lambda_c$ transition form factors and the helicity-dependent differential decay rates are collected in Appendices A and B, respectively.

2 The scalar and vector LQ scenarios

In this section, we recapitulate the scalar and vector LQ models, where a single TeV-scale scalar or vector LQ is added to the SM to address the aforementioned anomalies [16, 17]. For a recent comprehensive review of LQ models, the readers are referred to Ref. [88].

2.1 The scalar LQ scenario

Firstly, we consider the scalar LQ $\phi$ transforming as $(3, 1, -\frac{1}{3})$ under the SM gauge group, in which its couplings to SM fermions are described by the Lagrangian [16]

$$\mathcal{L}^\phi_{\text{int}} = \bar{Q}_L^c \lambda^L i\tau_2 L \phi^* + \bar{u}_R^c \lambda^R \ell_R \phi^* + \text{h.c.},$$

(2.1)

where $\lambda^{L,R}$ are the Yukawa coupling matrices in flavour space, and $Q_L, L$ denote the left-handed quark and lepton doublet, while $u_R, \ell_R$ the right-handed up-type quark and lepton singlet, respectively. The charge-conjugated spinors are defined as $\psi^c = C \bar{\psi}^T$, $\bar{\psi}^c = \psi^T C$ ($C = i\gamma^2\gamma^0$). Such a scalar $\phi$ mediates the $b \to c\tau\bar{\nu}_\tau$ decay at tree level, and the resulting effective weak Hamiltonian including the SM contribution is given as [16, 19]

$$\mathcal{H}_{\text{eff}} = \frac{4G_F V_{cb}}{\sqrt{2}} \left[ C_V c \gamma_\mu P_L b \tau \gamma^\mu P_L \nu_\tau + C_S c P_L b \tau P_L \nu_\tau - \frac{1}{4} C_T c \sigma_{\mu\nu} P_L b \tau \sigma^{\mu\nu} P_L \nu_\tau \right],$$

(2.2)

where $C_V, C_S, C_T$ are the Wilson coefficients of the corresponding four-fermion operators and, at the matching scale $\mu = M_\phi$, are given explicitly as

$$C_V(M_\phi) = 1 + \frac{\lambda^{L*}_L \lambda^{L*}_R}{4\sqrt{2}G_F V_{cb} M_\phi^2},$$

(2.3)

$$C_S(M_\phi) = C_T(M_\phi) = -\frac{\lambda^{L*}_L \lambda^{R*}_R}{4\sqrt{2}G_F V_{cb} M_\phi^2}.$$
In order to resum potentially large logarithmic effects, the Wilson coefficients \( C_S \) and \( C_T \) should be run down to the characteristic scale of the process we are interested in, \( i.e., \mu_b \sim m_b \), while \( C_V \) is not renormalized because of the conservation of vector currents. The explicit evolution equations could be found, for example, in Ref. [88].

As shown in Ref. [16], such a scalar LQ could explain the \( R_D^{(*)}, R_K \) and \( (g - 2)_{\mu} \) anomalies, while constraints from other precision measurements in the flavour sector can be satisfied without fine-tuning. Especially, under the constraints from both the ratios \( R_D^{(*)} \) and the measured \( q^2 \) spectra in \( B \to D^{(*)}\tau\bar{\nu}_\tau \) decays, four best-fit solutions are found for the operator coefficients induced by the scalar LQ [18], two of which are, however, already excluded by the purely leptonic \( B_c^- \to \tau^-\bar{\nu}_\tau \) decay [19]. Consequently, in this paper, we shall consider only the remaining two solutions denoted by \( P_A \) and \( P_C \) in Ref. [19].

### 2.2 The vector LQ scenario

We now introduce the second scenario in which the SM is extended by a vector \( SU(2)_L \) triplet \( U_3^\mu \) transforming as \((3, 3, 2/3)\) under the SM gauge group. The coupling of the vector multiplet \( U_3^\mu \) to a lepton-to-quark current with \((V - A)\) structure is given by [17]

\[
\mathcal{L}_{U_3} = g_{ij} \bar{Q}_i \gamma^\mu \tau^A U_3^A L_j + h.c.,
\]

(2.5)

where \( \tau^A \) \((A = 1, 2, 3)\) are the Pauli matrices in the \( SU(2)_L \) space, and \( L_i \) and \( Q_i \) \((i, j = 1, 2, 3)\) the left-handed lepton and quark doublets, respectively. The Lagrangian Eq. (2.5) is written in the fermion mass basis, with \( g_{ij} \) defined as the couplings of the \( Q = 2/3 \) component of the triplet, \( U_3^{(2/3)} \), to \( \bar{d}_i L_i \) and \( \ell_j L_j \). Expanding the \( SU(2)_L \) components, we get explicitly

\[
\mathcal{L}_{U_3} = U_3^{(2/3)} \left[ V g U \right]_{ij} \bar{u}_i \gamma^\mu P_L \nu_j - g_{ij} \bar{d}_i \gamma^\mu P_L \ell_j + h.c.,
\]

(2.6)

where \( V \) and \( U \) represent the Cabibbo-Kobayashi-Maskawa (CKM) [89, 90] and the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) [91, 92] matrix, respectively. Here we assume the neutrinos to
be massless and, therefore, the PMNS matrix can be rotated away through field redefinitions.

The vector multiplet \( U_3^\mu \) can also mediate the \( b \to c\tau\bar{\nu}_\tau \) transitions at tree level, and the resulting effective weak Hamiltonian including the SM contribution can be written as [17]

\[
H_{\text{eff}} = \frac{4G_F V_{cb}}{\sqrt{2}} C_V'(\bar{c}\gamma_\mu P_L b)(\bar{\tau}\gamma_\mu P_L \nu_\tau),
\]

(2.7)

where \( C_V' \) is the Wilson coefficient at the matching scale \( \mu = M_U \) and is given by

\[
C_V' = 1 + \frac{\sqrt{2} g^*_{br}(Vg)_{cr}}{4G_F V_{cb} M_U^2}.
\]

(2.8)

Unlike in the scalar LQ case, the vector LQ only generates \((V - A)\) couplings and, therefore, the Wilson coefficient \( C_V' \) need not be renormalized.

As shown in Ref. [17], the vector LQ scenario could also accommodate the \( R_{D(*)}, R_K \) as well as the angular observable \( P_3^\prime \) in \( B \to K^* \mu^+ \mu^- \) decay. Fitting to the measured ratios \( R_{D(*)} \), along with acceptable \( q^2 \) spectra, two best-fit solutions, denoted as \( R_A \) and \( R_B \), respectively, are found in this scenario [18]:

\[
g^*_{br}(Vg)_{cr} = \begin{cases} 
0.18 \pm 0.04, & R_A \\
-2.88 \pm 0.04, & R_B 
\end{cases},
\]

(2.9)

where \( M_U = 1 \text{TeV} \) is taken as a benchmark. It should be noted that the triplet nature of \( U_3^\mu \) also leads to various charged lepton-flavour-violating decays, such as the \( B \to K\mu\tau \) and \( \Upsilon(nS) \to \tau\mu \) decays, which have been discussed in Refs. [17, 86].

3 \( \Lambda_b \to \Lambda_c \ell\nu_\ell \) decays in scalar and vector LQ scenarios

3.1 Helicity amplitudes

In this subsection, we give the helicity amplitudes for the process \( \Lambda_b \to \Lambda_c \ell\nu_\ell \) both within the SM and in the two LQ scenarios. Following Refs. [24, 93] and starting with the effective weak Hamiltonian given by Eqs. (2.2) and (2.7), one can get the helicity amplitudes of the decay. Since all types of the leptonic helicity amplitudes can be found in Ref. [42], we give only the
hadronic helicity amplitudes. For the \((V - A)\)-type current, we have [24]

\[
H_{\lambda_2, \lambda_W} = H^{V}_{\lambda_2, \lambda_W} - H^{A}_{\lambda_2, \lambda_W} ; \quad H^{V(A)}_{\lambda_2, \lambda_W} = e^{\dagger \mu}(\lambda_W) (\Lambda_c, \lambda_2) \bar{c} \gamma_{\mu} (\gamma_5) b | \Lambda_b, \lambda_1 \rangle ,
\]

where \(\lambda_2\) and \(\lambda_W\) denote the helicities of the daughter baryon \(\Lambda_c\) and the effective (axial-)vector-type current, respectively. The explicit expressions of \(H_{\lambda_2, \lambda_W}\) in terms of the hadronic matrix elements defined by Eqs. (A.1) and (A.2) could be found in Ref. [24]. For the \((S - P)\)-type current, the corresponding helicity amplitudes are given by [23]

\[
H^{SP}_{\lambda_2, 0} = H^{S}_{\lambda_2, 0} - H^{P}_{\lambda_2, 0} ,
\]

\[
H^{SP}_{\pm, 0} = \frac{\sqrt{Q_+}}{m_b - m_c} \left( F^V_1 M_- + F^V_3 q^2 \langle M_1 \right) \pm \frac{\sqrt{Q_-}}{m_b + m_c} \left( F^A_1 M_+ - F^A_3 q^2 \langle M_1 \right) ,
\]

where we use the abbreviations \(M_{\pm} = M_{\Lambda_b} \pm M_{\Lambda_c}\) and \(Q_{\pm} = M_{\pm}^2 - q^2\). The hadronic helicity amplitudes of the (pseudo-)tensor-type current are defined as

\[
H^{T}_{\lambda_2, \lambda_W, \lambda_W'} = e^{\dagger \nu}(\lambda_W) e^{\dagger \mu}(\lambda_W') (\Lambda_c, \lambda_2) \bar{c} i \sigma_{\mu \nu} (1 - \gamma_5) b | \Lambda_b, \lambda_1 \rangle ,
\]

and their explicit expressions, in terms of the hadronic matrix elements defined by Eqs. (A.5) and (A.6), are given by

\[
H^{T}_{\frac{1}{2}, +, 0} = - \sqrt{\frac{2}{q^2}} \left( f_T \sqrt{Q_-} M_+ + g_T \sqrt{Q_+} M_- \right) ,
\]

\[
H^{T}_{\frac{1}{2}, +, -} = - f_T \sqrt{Q_+} - g_T \sqrt{Q_-} ,
\]

\[
H^{T}_{\frac{1}{2}, +, t} = - \sqrt{\frac{2}{q^2}} \left( f_T \sqrt{Q_-} M_+ + g_T \sqrt{Q_+} M_- \right) + \sqrt{2q^2} \left( f_T^Y \sqrt{Q_-} - g_T^Y \sqrt{Q_+} \right) ,
\]

\[
H^{T}_{\frac{1}{2}, 0, t} = - f_T \sqrt{Q_-} - g_T \sqrt{Q_+} + f_T^Y \sqrt{Q_-} M_+ - g_T^Y \sqrt{Q_+} M_- + f_T^S \sqrt{Q_-} Q_+ + g_T^S \sqrt{Q_+} Q_- ,
\]

\[
H^{T}_{\frac{1}{2}, 0, -} = f_T \sqrt{Q_+} - g_T \sqrt{Q_-} ,
\]

\[
H^{T}_{\frac{1}{2}, 0, -} = \sqrt{\frac{2}{q^2}} \left( f_T \sqrt{Q_-} M_+ - g_T \sqrt{Q_+} M_- \right) ,
\]

\[
H^{T}_{\frac{1}{2}, 0, t} = - f_T \sqrt{Q_-} + g_T \sqrt{Q_+} + f_T^Y \sqrt{Q_-} M_+ + g_T^Y \sqrt{Q_+} M_- + f_T^S \sqrt{Q_-} Q_+ - g_T^S \sqrt{Q_+} Q_- ,
\]

7
\[H_{T,\frac{1}{2}^-} = -\sqrt{\frac{2}{q^2}} \left( f_T \sqrt{Q_- M_+} - g_T \sqrt{Q_+ M_-} \right) + \sqrt{2q^2} \left( f_T^V \sqrt{Q_-} + g_T^V \sqrt{Q_+} \right). \quad (3.5)\]

The helicity amplitudes satisfy the relations \(H_{\lambda_2,\lambda W} = 0\) and \(H_{\lambda_2,\lambda W,\lambda W'} = -H_{\lambda_2,\lambda W,\lambda W'}\), while all the others are found to be zero. Using the HQET relations given by Eq. (A.7), we can further simplify these helicity amplitudes.

### 3.2 Observables in \(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell\) decays

Here we follow the conventions used in Refs. \[23, 24, 26\], and write the two-fold differential angular decay distribution as

\[
\frac{d^2\Gamma(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)}{dq^2 d\cos\theta_\ell} = N \left[ A_1 + \frac{m_\ell^2}{q^2} \left( A_2^V + A_2^T \right) + 2A_3 + \frac{4m_\ell}{\sqrt{q^2}} A_4 + A_5 \right],
\]

with

\[
N = \frac{G_F^2|V_{cb}|^2 q^2|\mathbf{p}_2|}{512\pi^3 m_{\Lambda_b}^2} \left( 1 - \frac{m_\ell^2}{q^2} \right)^2,
\]

\[
A_1 = C_V^2 \left[ 2\sin^2 \theta_\ell (H_{T,\frac{1}{2}^+}^2 + H_{T,\frac{1}{2}^-}^2) + (1 - \cos \theta_\ell)^2 H_{T,\frac{1}{2}^+}^2 + (1 + \cos \theta_\ell)^2 H_{T,\frac{1}{2}^-}^2 \right],
\]

\[
A_2^V = C_V^2 \left[ 2\cos^2 \theta_\ell (H_{T,\frac{1}{2}^+}^2 + H_{T,\frac{1}{2}^-}^2) + \sin^2 \theta_\ell (H_{T,\frac{1}{2}^+}^2 + H_{T,\frac{1}{2}^-}^2) + 2(H_{T,\frac{1}{2}^+}^2 + H_{T,\frac{1}{2}^-}^2) \right.
\]

\[
- 4\cos \theta_\ell (H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^-} H_{T,\frac{1}{2}^+}) \right],
\]

\[
A_2^T = \frac{C_T^2}{4} \left[ 2\sin^2 \theta_\ell (H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-}) \right.
\]

\[
+ (1 + \cos \theta_\ell)^2 (H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-}) \right).
\]

\[
A_3 = \frac{C_T^2}{8} \left[ 2\cos^2 \theta_\ell (H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-}) \right.
\]

\[
+ \sin^2 \theta_\ell (H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-} + 2H_{T,\frac{1}{2}^+} H_{T,\frac{1}{2}^-}) \right]
\]

\[
+ C_S^2 \left( H_{SP,\frac{1}{2}^+} H_{SP,\frac{1}{2}^-} \right),
\]

\[
A_4 = C_V C_S \left[ -\cos \theta_\ell (H_{T,\frac{1}{2}^+} H_{SP,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{SP,\frac{1}{2}^-}) + (H_{T,\frac{1}{2}^+} H_{SP,\frac{1}{2}^-} + H_{T,\frac{1}{2}^+} H_{SP,\frac{1}{2}^-}) \right].
\]

\[8\]
\[ + C_V C_T \left[ \frac{\cos^2 \theta}{2} \left( H_{\frac{1}{2},0}^{T\text{rest},+,-} + H_{\frac{1}{2},0}^{T\text{rest},0,\ell} + H_{-\frac{1}{2},0}^{T\text{rest},+,-} + H_{-\frac{1}{2},0}^{T\text{rest},0,\ell} \right) \\
- \frac{\cos \theta}{2} \left( H_{\frac{1}{2},0}^{T\text{rest},+,-} + H_{\frac{1}{2},0}^{T\text{rest},0,\ell} + H_{-\frac{1}{2},0}^{T\text{rest},+,-} + H_{-\frac{1}{2},0}^{T\text{rest},0,\ell} \right) \right] \\
+ \frac{(1 - \cos \theta)^2}{4} \left( H_{\frac{1}{2},0}^{T\text{rest},+,-} + H_{\frac{1}{2},0}^{T\text{rest},0,\ell} \right) \\
+ \frac{(1 + \cos \theta)^2}{4} \left( H_{-\frac{1}{2},0}^{T\text{rest},+,-} + H_{-\frac{1}{2},0}^{T\text{rest},0,\ell} \right) \\
+ \frac{\sin^2 \theta}{4} \left( H_{\frac{1}{2},0}^{T\text{rest},+,-} + H_{\frac{1}{2},0}^{T\text{rest},0,\ell} + H_{-\frac{1}{2},0}^{T\text{rest},+,-} + H_{-\frac{1}{2},0}^{T\text{rest},0,\ell} \right) \\
+ 2H_{\frac{1}{2},0}^{T\text{rest},+,-} + 2H_{\frac{1}{2},0}^{T\text{rest},+,-} + 2H_{-\frac{1}{2},0}^{T\text{rest},+,-} + 2H_{-\frac{1}{2},0}^{T\text{rest},+,-} \right] , \tag{3.7}\]

where \(|\vec{p}_2| = \sqrt{Q^2/(2M_{\Lambda_b})}\) is the \(\Lambda_c\) momentum in the \(\Lambda_b\) rest frame, \(q^2\) the momentum transfer squared, and \(\theta_e\) the polar angle of the lepton, as shown in Fig. 1 of Ref. [24]. Integrating out \(\cos \theta_e\) in Eq. (3.6), one can then obtain the differential decay rate \(d\Gamma(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)/dq^2\).

With Eqs. (3.6) and (3.7) at hand, we can get the following physical observables:

- The differential and total branching fractions

\[ \frac{d\mathcal{B}(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)}{dq^2} = \tau_{\Lambda_b} \frac{d\Gamma(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)}{dq^2} , \quad \mathcal{B}(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell) = \int_{m^2_\ell}^{M^2} \frac{dq^2}{dq^2} \frac{d\mathcal{B}}{dq^2} , \tag{3.8}\]

where \(\tau_{\Lambda_b}\) is the lifetime of \(\Lambda_b\) baryon, and \(m_\ell\) the lepton mass.

- The differential and integrated ratios

\[ R_{\Lambda_c}(q^2) = \frac{d\Gamma(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)/dq^2}{d\Gamma(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)/dq^2} , \quad R_{\Lambda_c} = \int_{m^2_\ell}^{M^2} \frac{dq^2}{dq^2} \frac{d\Gamma(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)/dq^2}{d\Gamma(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)/dq^2} . \tag{3.9}\]

- The lepton-side forward-backward asymmetry

\[ A_{FB}(q^2) = \frac{\int_{0}^{1} \frac{dq^2}{dq^2} \frac{d\Gamma}{dq^2} \cos \theta - \int_{-1}^{0} \frac{dq^2}{dq^2} \frac{d\Gamma}{dq^2} \cos \theta}{\frac{d\Gamma}{dq^2}} , \tag{3.10}\]

defined as the relative difference between the differential decay rates where the angle \(\theta_e\) is smaller or greater than \(\pi/2\).
Once the individual helicity-dependent differential decay rates are calculated, which are collected in Appendix B, we can obtain another two observables, the $q^2$-dependent longitudinal polarizations of $\Lambda_c$ baryon and $\tau$ lepton, which are defined, respectively, as

$$P_{\Lambda_c}^L(q^2) = \frac{d\Gamma_{\lambda_2=1/2}/dq^2 - d\Gamma_{\lambda_2=-1/2}/dq^2}{d\Gamma/dq^2}, \quad P_{\tau}^L(q^2) = \frac{d\Gamma_{\lambda_\tau=1/2}/dq^2 - d\Gamma_{\lambda_\tau=-1/2}/dq^2}{d\Gamma/dq^2}. \quad (3.11)$$

The above results are given for the scalar LQ scenario. For the vector LQ case, we need only to replace $C_V$ by $C'_V$ given by Eq. (2.8), while setting $C_S$ and $C_T$ to zero.

4 Numerical results and discussions

4.1 Input parameters

In this section, we investigate the scalar and vector LQ effects on the aforementioned observables, to see if their effects are large enough to cause sizable deviations from the corresponding SM predictions. Firstly, we collect in Table 1 all the input parameters used in this paper.

Table 1: Input parameters used in our numerical analyses.

| Parameter       | Value                        | Reference |
|-----------------|------------------------------|-----------|
| $G_F$           | $1.166378 \times 10^{-5}$ GeV$^{-2}$ | [94]     |
| $\alpha_s(M_Z)$| $0.1185 \pm 0.0006$          | [94]     |
| $M_Z$           | $91.188$ GeV                 | [94]     |
| $m_t$           | $(173.21 \pm 0.87)$ GeV      | [94]     |
| $m_b(m_b)$      | $(4.18 \pm 0.03)$ GeV        | [94]     |
| $m_c(m_c)$      | $(1.275 \pm 0.025)$ GeV      | [94]     |
| $\tau_{\Lambda_b}$ | $1.466$ ps                  | [94]     |
| $M_{\Lambda_b}$ | $5.61951$ GeV                | [94]     |
| $M_{\Lambda_c}$ | $2.28646$ GeV                | [94]     |
| $m_{\tau}$      | $1.7769$ GeV                 | [94]     |
| $m_{\mu}$       | $105.66$ MeV                 | [94]     |
| $m_e$           | $0.511$ MeV                  | [94]     |
| $|V_{cb}|$       | $(41.1 \pm 1.3) \times 10^{-3}$ | [94]     |
Table 2: Pole parameterizations of the $\Lambda_b \to \Lambda_c$ transition form factors for two values of $\kappa$ and for two choices of the continuum model in QCD sum rules [28].

| continuum model | $\kappa$ | $F_1^V(q^2)$ | $-F_2^V(q^2)/M_{\Lambda_b}$ |
|-----------------|----------|---------------|-----------------------------|
| rectangular     | 1        | 6.66/(20.27 $- q^2$) | -0.21/(15.15 $- q^2$) |
| rectangular     | 2        | 8.13/(22.50 $- q^2$) | -0.22/(13.63 $- q^2$) |
| triangular      | 3        | 13.74/(26.68 $- q^2$) | -0.41/(18.65 $- q^2$) |
| triangular      | 4        | 16.17/(29.12 $- q^2$) | -0.45/(19.04 $- q^2$) |

For the $\Lambda_b \to \Lambda_c$ transition form factors, we firstly use the results obtained in QCD sum rules [28], together with the HQET relations among the form factors [29–31]. Four types of form-factor parametrizations for two values of the parameter $\kappa$, which is introduced to account for deviations from the factorization hypothesis for four-quark condensates, and for two choices of the continuum model are shown in Table 2. For a comparison, we also adopt the latest lattice QCD results for the (axial-)vector form factors [25], where the $q^2$ dependence of the form factors is parameterized in a simplified $z$ expansion [95], modified to account for pion-mass and lattice-spacing dependence. All relevant formulae and input data can be found in Eq. (79) and Tables VII–IX of Ref. [25]. While for the (pseudo-)tensor form factors, since lattice result is unavailable so far, we still use the HQET relations to relate them to the corresponding (axial-)vector ones.

4.2 Numerical analyses

We now give our predictions for the branching fractions $\mathcal{B}(\Lambda_b \to \Lambda_c \ell \bar{\nu}_\ell)$ and the ratio $R_{\Lambda_c}$ both within the SM and in the scalar and the vector LQ scenarios in Table 3 with the form factors taken from QCD sum rules [28], and in Table 4 with the form factors taken from lattice QCD calculations [25]. The theoretical uncertainties in Table 3 come only from the NP parameters given by Eq. (2.9), whereas in Table 4 we have also included the uncertainties from the form-factor parameters following the procedure recommended in [25]. Specifically, we have taken into account the correlation matrices between the form-factor parameters, and calculate the central values, statistical uncertainties, and total systematic uncertainties of any observable depending on these parameters, according to Eqs. (82)–(84) specified in Ref. [25].
Table 3: Predictions for the branching fractions (in unit of $10^{-2}$) and the ratio $R_{\Lambda_c}$ of $\Lambda_b \rightarrow \Lambda_c \ell \bar{\nu}_\ell (\ell = e/\tau)$ decays both within the SM and in the scalar/vector LQ scenarios, with the form factors taken from QCD sum rules [28].

| $\kappa$ | $\mathcal{B}(\Lambda_b \rightarrow \Lambda_c e \bar{\nu}_e)$ | $\mathcal{B}(\Lambda_b \rightarrow \Lambda_c \tau \bar{\nu}_\tau)$ | $R_{\Lambda_c}$ |
|----------|-------------------------------------------------|-------------------------------------------------|--------------|
|          | $\mathcal{B}$ (SM) | $\mathcal{B}$ (SM) | scalar LQ | vector LQ | scalar LQ | vector LQ | $P_A$ | $P_C$ | $R_A$ | $R_B$ | $P_A$ | $P_C$ | $R_A$ | $R_B$ |
| 1        | 2.50 | 0.74 | 0.93 | 0.95 | 0.05 | 0.94 | 0.05 | 0.30 | 0.38 | 0.37 | 0.38 | 0.02 | 0.37 | 0.02 |
| 2        | 2.67 | 0.73 | 0.93 | 0.91 | 0.93 | 0.05 | 0.92 | 0.05 | 0.27 | 0.35 | 0.34 | 0.35 | 0.02 | 0.34 | 0.02 |
| 3        | 5.16 | 1.30 | 1.77 | 1.73 | 1.78 | 0.09 | 1.75 | 0.09 | 0.27 | 0.35 | 0.34 | 0.35 | 0.02 | 0.34 | 0.02 |
| 4        | 5.74 | 1.50 | 1.92 | 1.88 | 1.93 | 0.10 | 1.90 | 0.10 | 0.26 | 0.34 | 0.33 | 0.34 | 0.02 | 0.33 | 0.02 |

Table 4: Same as in Table 3 but with the form factors taken from lattice QCD calculation [25].

| $\mathcal{B}(\Lambda_b \rightarrow \Lambda_c e \bar{\nu}_e)$ | SM | 5.34 ± 0.33 |
|-------------------------------------------------|-----------------|
| $\mathcal{B}(\Lambda_b \rightarrow \Lambda_c \tau \bar{\nu}_\tau)$ | SM | 1.77 ± 0.09 |
| scalar LQ | $P_A$ | 2.26 ± 0.12 |
| vector LQ | $R_A$ | 2.27 ± 0.17 |
| $R_{\Lambda_c}$ | $R_B$ | 2.24 ± 0.17 |

From the numerical results given in Tables 3 and 4, we can draw the following conclusions:

- The branching fractions are very sensitive to the form-factor parameterizations used in QCD sum rules [28]. The triangular region (with $\kappa = 3$ or $\kappa = 4$) for the continuum model gives more reliable predictions compared to the rectangular one, because, within the SM, the former leads to consistent results with that obtained using the lattice-based
form factors, and also with the experimental data $\mathcal{B}(\Lambda_b \to \Lambda_c e \bar{\nu}_e) = (6.5^{+3.2}_{-2.5})\%$ \cite{94}. Thus, from now on, we consider only the triangular continuum model with two different values of $\kappa$. The ratio $R_{\Lambda_c}$, on the other hand, is insensitive to the form-factor parameterizations, as is generally expected. It is also noted that the predicted $R_{\Lambda_c}$ using the lattice-based form factors is a little bit larger than that obtained from QCD sum rules, both within the SM and in the two LQ scenarios.

- In the scalar LQ scenario, the predicted branching fraction $\mathcal{B}(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)$ is enhanced by about 28% (25%) in the $P_A$ ($P_C$) case, no matter the form factors are taken from QCD sum rules or from the lattice QCD calculations. The slight difference between the two solutions results from the $\sim 1.2\%$ numerical difference in the dominated coefficient $|C_V^f|$, which has been discussed in Ref. \cite{19}. As the decay modes with light leptons ($\ell = e, \mu$) are assumed to be free from the scalar LQ contribution, the ratio $R_{\Lambda_c}$ is also enhanced by the corresponding percentages relative to the SM prediction.

- In the vector LQ scenario, compared to the SM prediction, the branching fraction $\mathcal{B}(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)$ is found to be enhanced by about 28% in the $R_A$ and by about 27% in the $R_B$ case, respectively. To understand this, we should note that there is only one ($V - A$) coupling in this scenario, and the resulting effective coefficients $C_V^f$, corresponding to the two solutions $R_A$ and $R_B$ (cf. Eq. (2.9)), are given, respectively, as

$$
C_V^{\text{fit}} = \begin{cases} 
1.133 \pm 0.030, & \text{for } R_A \\
-1.124 \pm 0.030, & \text{for } R_B 
\end{cases} \quad (4.1)
$$

One can see clearly that, just like $C_V^f$ in scalar LQ scenario, $C_V^{\text{fit}}$ also has nearly the same absolute values for the two solutions $R_A$ and $R_B$, both enhancing the SM result by $\sim 13\%$, but the sign of solution $R_B$ is flipped relative to the SM part.

- As the two effective couplings $|C_V^f|$ and $|C_V^{\text{fit}}|$ are both enhanced by about $12\% \sim 13\%$, compared to the SM part, they would give quite similar predictions for the other observables in $\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau$ decay.

The $q^2$ dependences of the differential branching fraction $d\mathcal{B}(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)/dq^2$ and the ratio $R_{\Lambda_c}(q^2)$ are displayed in Fig. 1, both within the SM and in the two LQ scenarios. As the results
Figure 1: The $q^2$ distributions of the differential branching fraction $d\mathcal{B}(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)/dq^2$ ((a): in the scalar and (b): in the vector scenario) and the ratio $R_{\Lambda_c}(q^2)$ ((c): in the scalar scenario and (d): in the vector scenario). The bands in (a) and (c) due to the uncertainties of form-factor parameters obtained in lattice QCD, and in (b) and (d) also include the varying of the NP parameters in the vector scenario based on the form-factor parametrizations with $\kappa = 3$ are similar to that with $\kappa = 4$, we show only the case with $\kappa = 3$. One can see that these two observables present the same features as the corresponding $q^2$-integrated ones discussed above: The predicted $d\mathcal{B}(\Lambda_b \to \Lambda_c \tau \bar{\nu}_\tau)/dq^2$ using the lattice-based form factors are a little bit larger than that based on QCD sum rules, and are enhanced at $q^2 \sim 9\text{GeV}^2$ at most in both the two LQ scenarios. However, the ratio $R_{\Lambda_c}(q^2)$ is insensitive to the choices of the form factors.

Finally, we show in Fig. 2 the $q^2$ dependences of the $\Lambda_c$ and $\tau$ longitudinal polarizations as well as the lepton-side forward-backward asymmetry. Since the resulting effective coefficients $C_V$ and $C_V'$ of the dominated $(V - A)$ couplings appear both in the numerator and in the denominator of these ratios, the NP effects are cancelled exclusively. At the same time, the
Figure 2: The $q^2$ dependences of the $\Lambda_c$ (a) and $\tau$ (b) longitudinal polarizations as well as the lepton-side forward-backward asymmetry (c), both within the SM and in the two LQ scenarios. The form-factor dependences of these observables are reduced to a large extent, and all the four cases in QCD sum rules ($\kappa = 1, \cdots, 4$) give almost the same curves for each observable, while being only slightly different from that obtained with the lattice-based form factors, as shown in Fig. 2. As a consequence, all these three observables are insensitive to the two LQ scenarios and behave nearly the same as in the SM.

5 Conclusions

As demonstrated in Refs. [16–18], both the scalar and vector LQ scenarios could explain the anomalies observed in $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_{\tau}$ and $\bar{B} \rightarrow \bar{K}\ell^+\ell^-$ decays and, for each scenario, there exist two best-fit solutions for the operator coefficients, because the other two solutions for scalar LQ are already excluded by the $B^+_c \rightarrow \tau^-\bar{\nu}_{\tau}$ decay [19]. To further explore these two interesting scenarios, in this paper, we have studies their effects in the semi-leptonic $\Lambda_b \rightarrow \Lambda_c\tau\bar{\nu}_{\tau}$ decay, which is induced by the same quark-level transition as in $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_{\tau}$ decays. Besides the branching fraction $\mathcal{B}(\Lambda_b \rightarrow \Lambda_c\tau\bar{\nu}_{\tau})$ and the ratio $R_{\Lambda_c}$, we have also discussed the $q^2$ distributions of these two observables, as well as the $\Lambda_c$ and $\tau$ longitudinal polarizations and the lepton-side forward-backward asymmetry, using the $\Lambda_b \rightarrow \Lambda_c$ transition form factors from both the QCD sum rules and the latest lattice QCD calculations.

Using the best-fit solutions for the operator coefficients allowed by the current data of mesonic decays, we have found that the two LQ scenarios give the similar amounts of enhancements relative to the SM predictions for the branching fraction $\mathcal{B}(\Lambda_b \rightarrow \Lambda_c\tau\bar{\nu}_{\tau})$ and the ratio $R_{\Lambda_c}$. The two best-fit solutions in each of the two scenarios are still found to be indistinguish-
able from each other based only on these two observables. On the other hand, both of the two LQ scenarios give nearly the same predictions as the SM for the $\Lambda_c$ and $\tau$ longitudinal polarizations, as well as the lepton-side forward-backward asymmetry. As a consequence, we conclude that, while the two LQ scenarios could be distinguished from the SM, it is quite difficult to distinguish between them using the semi-leptonic $\Lambda_b \rightarrow \Lambda_c \tau \bar{\nu}_\tau$ decay.

With the large number of $\Lambda_b$ produced at the LHC, we expect that, with future measurements of the observables in $\Lambda_b \rightarrow \Lambda_c \tau \bar{\nu}_\tau$ decay at the LHCb, the two LQ scenarios could be further tested, and even differentiated from the other NP explanations to the $R_{D(*)}$ anomalies.

**A $\Lambda_b \rightarrow \Lambda_c$ transition form factors**

The hadronic matrix elements of the vector and axial-vector currents between the two spin-half baryons $\Lambda_b$ and $\Lambda_c$ can be parameterized in terms of three form factors, respectively, as [24]

\[
\langle \Lambda_c, \lambda_2 | \bar{c} \gamma_\mu b | \Lambda_b, \lambda_1 \rangle = \bar{u}_2(p_2, \lambda_2) \left[ F^V_1(q^2) \gamma_\mu - \frac{F^V_2(q^2)}{M_{\Lambda_b}} i \sigma_{\mu\nu} q^\nu + \frac{F^V_3(q^2)}{M_{\Lambda_b}} q_\mu \right] u_1(p_1, \lambda_1),
\]

\[
\langle \Lambda_c, \lambda_2 | \bar{c} \gamma_\mu \gamma_5 b | \Lambda_b, \lambda_1 \rangle = \bar{u}_2(p_2, \lambda_2) \left[ F^A_1(q^2) \gamma_\mu - \frac{F^A_2(q^2)}{M_{\Lambda_b}} i \sigma_{\mu\nu} q^\nu + \frac{F^A_3(q^2)}{M_{\Lambda_b}} q_\mu \right] \gamma_5 u_1(p_1, \lambda_1),
\]

where $\sigma_{\mu\nu} = \frac{i}{2} (\gamma_\mu \gamma_\nu - \gamma_\nu \gamma_\mu)$, $q = p_1 - p_2$ is the four-momentum transfer, and $\lambda_i = \pm \frac{1}{2}$ ($i = 1, 2$) denote the helicities of the $\Lambda_b$ and $\Lambda_c$ baryons, respectively. Using the equations of motion, we
can then obtain the hadronic matrix elements of the scalar and pseudo-scalar currents between
the two baryons, which are given, respectively, as
\[
\langle \Lambda_c, \lambda_2 | \bar{c} b | \Lambda_b, \lambda_1 \rangle = \frac{1}{m_b - m_c} \bar{u}_2(p_2, \lambda_2) \left[ F_V^1(q^2)(M_1 - M_2) + \frac{F_V^3(q^2)}{M_{\Lambda_b}} q^2 \right] u_1(p_1, \lambda_1), \quad (A.3)
\]
\[
\langle \Lambda_c, \lambda_2 | \bar{c} \gamma_5 b | \Lambda_b, \lambda_1 \rangle = \frac{1}{m_b + m_c} \bar{u}_2(p_2, \lambda_2) \left[ F_A^1(q^2)(M_1 + M_2) - \frac{F_A^3(q^2)}{M_{\Lambda_b}} q^2 \right] \gamma_5 u_1(p_1, \lambda_1), \quad (A.4)
\]
where \( m_b \) and \( m_c \) are the current quark masses evaluated at the scale \( \mu \sim m_b \).

The hadronic matrix elements of the tensor and pseudo-tensor currents between the \( \Lambda_b \) and \( \Lambda_c \) baryons can be generally parameterized as [96]
\[
\langle \Lambda_c, \lambda_2 | \bar{c} i \sigma_{\mu \nu} b | \Lambda_b, \lambda_1 \rangle = \bar{u}_2(p_2, \lambda_2) \left[ f_T i \sigma_{\mu \nu} + f_T^V (\gamma_\mu q_\nu - \gamma_\nu q_\mu) + f_T^S (P_\mu q_\nu - P_\nu q_\mu) \right] u_1(p_1, \lambda_1), \quad (A.5)
\]
\[
\langle \Lambda_c, \lambda_2 | \bar{c} i \sigma_{\mu \nu} \gamma_5 b | \Lambda_b, \lambda_1 \rangle = \bar{u}_2(p_2, \lambda_2) \left[ g_T i \sigma_{\mu \nu} + g_T^V (\gamma_\mu q_\nu - \gamma_\nu q_\mu) + g_T^S (P_\mu q_\nu - P_\nu q_\mu) \right] \gamma_5 u_1(p_1, \lambda_1), \quad (A.6)
\]
where \( P = p_1 + p_2 \). The \( \Lambda_b \to \Lambda_c \) transition form factors have also been studies based on the HQET [29–31], and the following relations among the form factors can be found [96]:

\[
F_V^1 = F_A^1 = f_T = g_T, \quad (A.7)
\]
\[
F_V^2 = F_A^2 = -F_V^3 = -F_A^3, \quad (A.8)
\]
\[
f_T^V = g_T^V = f_T^S = g_T^S = 0. \quad (A.9)
\]

An alternate helicity-based definition of the \( \Lambda_b \to \Lambda_c \) form factors can be found in Ref. [97], and the explicit relations between these two sets of form factors are also given in Ref. [97].

In this paper, we use the results obtained both in the QCD sum rules [97] and in the most recent lattice QCD calculation with 2 + 1 dynamical flavours [25]. However, since there are currently no lattice results for the (pseudo-)tensor form factors yet, we still use the following HQET relations to relate them to the corresponding (axial-)vector ones,

\[
f_T = g_T = F_V^1 = \frac{(M_{\Lambda_b} + M_{\Lambda_c})^2 f_+ - q^2 f_+}{(M_{\Lambda_b} + M_{\Lambda_c})^2 - q^2}, \quad f_T^V = g_T^V = f_T^S = g_T^S = 0. \quad (A.10)
\]
B Helicity-dependent differential decay rates

In order to discuss the $\Lambda_c$ and $\tau$ polarizations, we need the helicity-dependent differential decay rates, which are collected below (normalized by the prefactor $N$ defined in Eq. (3.7)):

$$
\frac{d\Gamma_{\lambda_2=1/2}}{dq^2} = \frac{m_T^2}{q^2} \left[ \frac{4}{3} C_V (H_{1/2,+}^2 + H_{1/2,+}^2 + 3H_{1/2,+}^2) + \frac{2}{3} C_T (H_{1/2,+}^2 + H_{3/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2) \\
+ 2H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2 \right] + \frac{8}{3} C_V (H_{1/2,+}^2 + H_{3/2,+}^2) + 4C_S H_{3/2,+}^2 \\
+ \frac{C_T^2}{3} \left( H_{1/2,+}^2 + H_{1/2,+}^2 + H_{3/2,+}^2 + H_{3/2,+}^2 \right) + 2H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2 \\
+ \frac{4m_T}{\sqrt{q^2}} \left[ C_V C_T (H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2 + H_{1/2,+}^2) \right] + 2C_V C_S (H_{1/2,+}^2 H_{3/2,+}^2) \\
+ \frac{d\Gamma_{\lambda_2=-1/2}}{dq^2} = \frac{m_T^2}{q^2} \left[ \frac{4}{3} C_V (H_{1/2,-}^2 + H_{1/2,-}^2 + 3H_{1/2,-}^2) + \frac{2}{3} C_T (H_{1/2,-}^2 + H_{3/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2) \\
+ 2H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2 \right] + \frac{8}{3} C_V (H_{1/2,-}^2 + H_{3/2,-}^2) + 4C_S H_{3/2,-}^2 \\
+ \frac{C_T^2}{3} \left( H_{1/2,-}^2 + H_{1/2,-}^2 + H_{3/2,-}^2 + H_{3/2,-}^2 \right) + 2H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2 \\
+ \frac{4m_T}{\sqrt{q^2}} \left[ C_V C_T (H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2 + H_{1/2,-}^2) \right] + 2C_V C_S (H_{1/2,-}^2 H_{3/2,-}^2) \\
+ \frac{d\Gamma_{\lambda_3=1/2}}{dq^2} = \frac{m_T^2}{q^2} \left[ \frac{4}{3} C_V (H_{3/2,+}^2 + H_{3/2,+}^2 + 3H_{3/2,+}^2) + 3(H_{3/2,+}^2 + H_{3/2,+}^2) \right] + 4C_S (H_{3/2,+}^2 + H_{3/2,+}^2) \\
