(Dated: April 29, 2010)

Using the radiative return method, experiments at high luminosity electron-positron colliders allow to explore the kaon and the pion form factors in the time-like region up to fairly high energies. This opens the possibility to study kaon and pion pair production at and around the narrow resonances $J/\psi$ and $\psi(2S)$ and explore the interference between electromagnetic and hadronic amplitudes. Parameterizations of charged and neutral kaon as well as pion form factors are derived, which lead to an improved description of the data in the region of large invariant masses of the meson pair. These form factors are combined with the hadronic couplings of charged and neutral kaons to $J/\psi$ and $\psi(2S)$ and implemented into the Monte Carlo generator PHOKHARA, which is now, for the first time, able to simulate the production of narrow resonances and their decay into kaon, pion and muon pairs.

I. INTRODUCTION

New and precise measurements of the cross section for electron-positron annihilation into hadrons have been performed during the past years which were based on the method of “Radiative Return” [1, 2]. Exclusive reactions, specifically two-body final states like $\pi^+\pi^-$ [3, 4], $pp$ [5] or $\Lambda\bar{\Lambda}$ [6] and three- $\pi^+\pi^0$ [7] and four-meson final states $\pi^+\pi^-\pi^0\pi^0$ [8] have been explored. An important ingredient in these analyses was and is the simulation of all these reactions through a Monte Carlo generator. In a first step, the generator EVA was developed [2, 11], which is based on leading order matrix elements combined with structure function methods for an improved treatment of initial state radiation. Subsequently the complete next-to-leading order (NLO) QED corrections were evaluated [12, 13] and implemented into the generator PHOKHARA [14–22], which is now available for a variety of exclusive final states. (For a recent review of theoretical and experimental results see e.g. [23].) B-meson factories, operating at energies around 10 GeV and with high luminosity, allow to explore hadronic final states with relatively large invariant masses, up to 3 GeV and beyond. Therefore, the narrow resonances $J/\psi$ and $\psi(2S)$ can be studied through the radiative return, in particular in decay channels of low multiplicity, leptonic ones like $\mu^+\mu^-$ [24], or two-body hadronic modes like $\pi^+\pi^-$, $K^+K^-$, $K^0\bar{K}^0$, $pp$. The signal is identified with the help of a very good mass resolution and particle identification in the resonance region.

For an analysis exploiting the large statistics, the inclusion of radiative corrections from initial- and final-state radiation (ISR and FSR) is mandatory, since it affects the cross section and the line shape of the resonance. For the simulation of hadronic final states both the electromagnetic contribution, i.e. a parameterization of the form factor, and the strength of the direct coupling of the resonance to the hadrons are required. The latter is absent for final states with positive G-parity (2$\pi$, 4$\pi$, ...) but non-vanishing e.g. for $K\bar{K}$, 3$\pi$ or final states with baryons. On the other hand, a careful analysis of the resonance line shape in the various channels would allow a model-independent determination of the direct coupling and of the form factors close to resonance [25–31].

With this motivation in mind we reanalyze the pion and kaon form factors with emphasis on the region above the $\rho$-resonance. The basic ingredients are very similar to those employed in an earlier study [32]. However, additional assumptions are required to properly describe the different resonance-like structures in the energy region between 1 GeV and 3 GeV. The details of this model and its parameters are described in sections II and III for pions and kaons, respectively. The new implementation of these modes into PHOKHARA, which includes, as before, NLO ISR and FSR, is presented in Section IV. Section V is concerned with the implementation of the narrow resonances in the channels $\mu^+\mu^-$, $\pi^+\pi^-$, $K^+K^-$ and $K^0\bar{K}^0$. Hadronically and electromagnetically induced amplitudes are included, together with the radiative corrections from ISR and FSR. Section VI contains a brief summary and our conclusions.
II. THE PION FORM FACTOR

For a realistic generation a model for the electromagnetic form factor is required. The ansatz presented in [32] was published before the CLEO-c measurement of the form factor in the vicinity of the \(\psi(2S)\) resonance [33] and underestimates the experimental result significantly. The same applies to the model predictions at \(J/\psi\) as compared to the pion form factor calculated in [31] from \(B(J/\psi \rightarrow \pi^+\pi^-)\) and \(B(J/\psi \rightarrow e^+e^-)\) decay rates.

To accommodate the new data, the updated model ansatz for the pion form factor is taken similarly to [32]

\[
F_\pi(s) = \left[ \sum_{n=0}^{N} c_{\rho_n}^\pi BW_{\rho_n}(s) \right]_{\text{fit}} + \left[ \sum_{n=(N+1)}^{\infty} c_{\rho_n}^\pi BW_{\rho_n}(s) \right]_{\text{dQCD}},
\]

however, with different set of parameters. Those of the first \(N+1\) \(\rho\) radial excitations are fitted and the rest is taken from the “dual QCD model” [33]. It is necessary to take \(N = 5\) to fit the data. For the precise treatment of \(\rho_4\) and \(\rho_5\) see below.

For the Breit-Wigner function we adopt the Gounaris-Sakurai [35] version with pion loop corrections included:

\[
BW_{\rho_n}(s) = \frac{m_{\rho_n}^2 - s + H(s) - \sqrt{s} \Gamma_{\rho_n}(s)}{m_{\rho_n}^2 - s + H(s) - i\sqrt{s} \Gamma_{\rho_n}(s)},
\]

where

\[
H(s) = \hat{H}(s) - \hat{H}(m_{\rho_n}^2) - (s - m_{\rho_n}^2) \frac{d}{ds} \hat{H}(m_{\rho_n}^2),
\]

\[
\hat{H}(s) = \left( \frac{m_{\rho_n}^2 \Gamma_{\rho_n}}{2\pi[p(m_{\rho_n})]^3} \right) \left( \frac{s}{4} - m_{\rho_n}^2 \right) \times v(s) \log \frac{1 + v(s)}{1 - v(s)},
\]

\[
p(s) = \frac{1}{2} (s - 4m_\pi^2)^{1/2}, \quad v(s) = \sqrt{1 - \frac{4m_\pi^2}{s}}.
\]

Correspondingly we use the \(s\)-dependent widths

\[
\Gamma_{\rho_n}(s) = \frac{m_{\rho_n}^2}{s} \left( \frac{p(s)}{p(m_{\rho_n}^2)} \right)^3 \Gamma_{\rho_n} \theta(s - 4m_\pi^2).
\]

which are taken from two-body \(P\)-wave final states and for simplicity (and lack of experimental information) also used for the rest of decay channels [32]. In Eqs. [41] and [42] we have used \(\Gamma_{\rho_n} \equiv \Gamma_{\rho_n}(s = m_{\rho_n}^2)\), which is the total width of the \(\rho_n\) meson. The constraint \(\sum_{n=0}^{\infty} c_{\rho_n}^\pi = 1\) together with \(BW_{\rho_n}(0) = 1\) enforces the proper normalization of the form factor \(F_\pi(0) = 1\).

For the ground state \(\rho(770)\) isospin violation from \(\rho - \omega\) mixing is taken into account by substituting...
c_{\rho_\omega}^\pi BW_{\rho_\omega}(s) \to \frac{c_{\rho_\omega}^\pi BW_{\rho_\omega}(s)}{1 + c_{\omega}^\rho BW_{\omega}}(1 + c_{\omega}^\rho BW_{\omega}). \hspace{1cm} (7)

A Breit-Wigner function with constant width

\[ BW_{\omega} = \frac{m_{\omega}^2}{m_{\omega}^2 - s - i m_{\omega} \Gamma_{\omega}}, \]  \hspace{1cm} (8)

is used for description of the \( \omega \) resonance.

As discussed in the Introduction, the couplings \( c_{\rho_\omega}^\pi \) are based on the ansatz predicted in the dual-QCD\(_{N_c=\infty}\) model [36].

\[ c_{\rho_\omega}^\pi = \frac{(-1)^n \Gamma(\beta - 1/2)}{\alpha' m_{\rho_\omega}^2 \sqrt{\pi} (n + 1) \Gamma(\beta - 1 - n)}, \hspace{1cm} (9) \]

where \( \alpha' = 1/(2m_{\rho_\omega}^2) \) is the slope of the Regge trajectory \( \alpha_\rho(s) = 1 + \alpha'(s - m_{\rho_\omega}^2) \). The model postulates an equidistant mass spectrum \( m_{\rho_\omega}^2 = m_{\rho_\omega}^2 (1 + 2n) \) and a linear relation between mass and width of a given resonance \( \Gamma_{\rho_\omega} = \gamma m_{\rho_\omega} \), with \( \gamma \) derived from the lowest resonance. The parameters \( \beta \) and \( m_{\rho_\omega} \) are to be taken from the fit.

We fit the data in the time-like region which provides detailed information about the structure of the resonances and coincides with the region relevant for the PHOKHARA Monte Carlo generator.

We have used new data [3, 31, 33, 38, 42], whenever possible. They are more accurate and the treatment of radiative corrections is well documented. Furthermore, we adopt the theoretical extraction of the pion form factor at \( J/\psi \) using [31]

\[ |F_\pi|^2 = \frac{4B(J/\psi \to \pi^+\pi^-)}{\beta_\pi^2 B(J/\psi \to e^+e^-)}, \hspace{1cm} (10) \]

where \( \beta_\pi = \sqrt{1 - 4m_{\pi}^2/M_{\pi}^2} \) and recent experimental data [34].

If one would assume independent point to point statistical and systematic errors of the new data [3, 38, 42] and combine these in quadrature the results would be inconsistent and no fit could be made. Summing linearly the statistical and systematic experimental errors for each experimental data point one finds very good agreement between the experimental data. This approach will be adopted below. The new BaBar data [4] become available only after our analysis was finished and we include here only their part (above 1.2 GeV). The BaBar data below 1.2 GeV are in conflict with KLOE data and further investigations would be required how to merge these conflicting data samples.

In [3, 38, 42] the form factor including vacuum polarization was measured. We prefer to parameterize the ‘bare’ form factor \( F_\pi \) (see [25] for definition), which is used throughout this paper and for example directly obtained in Eq. (10). The vacuum polarization corrections are taken from [20, 43]. For the extraction of the form factor from the cross section, the CLEO-c collaboration [33] has corrected for the leptonic part of the vacuum polarization effects. Hence their result has still to be corrected only for the hadronic part, which corresponds to a 1.5% shift of \( |F_\pi|^2 \) only and is irrelevant at the present experimental precision.

| Parameter | model(fit) | PDG value | model |

**TABLE I: Parameters of the pion form factor (Eq. (7) and Eq. (10)) and results of the fit to the data.**

We have attempted to fit the experimental data keeping the coupling constants \( c_{\rho_\omega}^\pi \) fixed to the model values (one fit parameter \( \beta \) for all of them) and fitting only the masses and the widths of the first few resonances (up to \( n = 5 \)). This parameterization is satisfactory up to \( \sqrt{s} \sim 1.3 - 1.4 \) GeV, where the details of the model for resonances, with \( n = 2 \) and higher, are not important. However, the model is definitely too simple for a description of the details of higher radial excitations including issues like coupled channels in decays of the higher radial \( \rho \) excitations. Hence we adopt a heuristic approach, where we allow for arbitrary complex couplings \( f_n \) of the \( \rho_n \) (\( n = 1, 2, 3, 4, 5 \))...
The mass and the width of \( \rho_3 \) are fixed to their values obtained in the fit to the four pion production data [22]. For the masses and widths of the higher excitations \( (n \geq 4) \) we use their model values.

The results are shown in Table I. The fitted value of \( m_{\rho_0} \) is smaller than its PDG2008 [34] value, a consequence of using the dressed form factor in [38–42]. This phenomenon was also observed in [44]. The parameters describing the radial \( \rho \) excitations obtained in the fit have to be taken with great care as they are strongly correlated, while in Table I we give only MINOS (MINUIT procedure from CERNLIB) parabolic errors.

To illustrate the numerical importance of the higher radial excitations within the “dual QCD model” in Fig. 2 we show the relative difference between the full modulus square of the pion form factor and the result calculated with the first six resonances which were used in the fit. It is evident that it is impossible to neglect the higher resonances and even in the \( \rho_0 \) region they give small, but not negligible contribution to the form factor.

### III. THE KAON FORM FACTOR

The kaon form factors were revisited for the same reasons as the pion form factor. Compared to the CLEO-c result, the model presented in [32] underestimates the kaon form factor in the vicinity of the \( \psi(2S) \) resonance. It is impossible to fit the existing data, including the CLEO-c result, with the functional form used in [32] or adding one or two more radial excitations, unless one would accept inclusion of a huge wide resonance in the region between \( J/\psi \) and \( \psi(2S) \). To cure the situation, a model analogous to the one used for the pion form factor, assuming an infinite tower of resonances, was adopted. The ansatz reads

\[
F_{K^+(s)} = \frac{1}{2} \left[ \sum_{n=0}^{N_o} c_{\rho_n}^{K} \mathcal{B} W_{\rho_n}(s) \right]_{fit} + \left[ \sum_{n=N_o+1}^{\infty} c_{\rho_n}^{K} \mathcal{B} W_{\rho_n}(s) \right]_{dQCD}
+ \frac{1}{6} \left[ \sum_{n=0}^{N_o} c_{\omega_n}^{K} \mathcal{B} W_{\omega_n}(s) \right]_{fit} + \left[ \sum_{n=N_o+1}^{\infty} c_{\omega_n}^{K} \mathcal{B} W_{\omega_n}(s) \right]_{dQCD}
+ \frac{1}{3} \left[ \sum_{n=0}^{N_o} c_{\phi_n}^{K} \mathcal{B} W_{\phi_n}(s) \right]_{fit} + \left[ \sum_{n=N_o+1}^{\infty} c_{\phi_n}^{K} \mathcal{B} W_{\phi_n}(s) \right]_{dQCD},
\]

\[
F_{K^0}(s) = -\frac{1}{2} \left[ \sum_{n=0}^{N_o} c_{\rho_n}^{K} \mathcal{B} W_{\rho_n}(s) \right]_{fit} + \left[ \sum_{n=N_o+1}^{\infty} c_{\rho_n}^{K} \mathcal{B} W_{\rho_n}(s) \right]_{dQCD}
+ \frac{1}{6} \left[ \sum_{n=0}^{N_o} c_{\omega_n}^{K} \mathcal{B} W_{\omega_n}(s) \right]_{fit} + \left[ \sum_{n=N_o+1}^{\infty} c_{\omega_n}^{K} \mathcal{B} W_{\omega_n}(s) \right]_{dQCD}
\]
The couplings in the part with subscript \textit{fit} were fitted to the experimental data as well as the constants \( \eta_\phi \) and \( c^K_\phi \). The values of \( N_\rho, N_\omega \) and \( N_\phi \) are listed in Table \[ ] The entry PDG in Table \[ ] implies, that masses and widths as given in PDG2008 \[ ] were used. The masses and widths of the radial excitations, which were not measured, were calculated assuming an equidistant mass spectrum and a linear relation between the mass and the width of a given resonance

\[
m^2_j = m^2_j (1 + 2n), \quad \Gamma_j = \gamma_j m_j, \quad j = \rho, \omega, \phi. \tag{14}
\]

The value of \( \gamma_\rho \) was calculated from Eq.\[ ] for \( n = 0 \), the other values were fitted to the data.

Two versions of the model were investigated: the ‘unconstrained’ version were the couplings between kaons and \( \rho_n, \omega_n \) and \( \phi_n \) are not related and the ‘constrained’ version were \( c^K_\omega = c^K_\rho, \quad n = 0, \ldots, \infty \). The ‘constrained’ model is not able to reproduce data as good as the ‘unconstrained’ model, however as evident from Tab.\[ ] the corrections to the assumption \( c^K_\omega = c^K_\rho \) are small for the lowest two resonances.

Despite this, the two models predict completely different asymptotic behaviour of the neutral kaon form factor in the region, where no data are available (Fig.\[ ]). The ‘constrained’ model, being closer to the SU(3) symmetric case where the neutral kaon form factor vanishes, arrives at significantly smaller predictions. The values of the couplings, which were not fitted, were calculated from the formula

\[
c^K_j = \frac{(-1)^n \Gamma_j (\beta_j^K - 1/2)}{\alpha' \sqrt{n} m^2_j \Gamma (n + 1) \Gamma (\beta_j^K - 1 - n)}, \quad \alpha' = 1/(2m^2_j), \quad j = \rho, \omega, \phi \tag{15}
\]

with the exception of the couplings next to the last fitted, which were calculated from the normalization requirements

\[
\sum_{n=0}^{\infty} c^K_j = 1, \quad j = \rho, \omega, \phi. \tag{16}
\]

Breit-Wigner propagators

\[
BW^c_\alpha = \frac{m^2_\alpha}{m^2_\alpha - s - im_\alpha \Gamma_\alpha}, \quad \alpha = \omega_n \tag{17}
\]
with constant widths were used for all $\omega_n$, Breit-Wigner propagators with s-dependant widths

$$BW_{\phi_n}^j = \frac{m_{\phi_n}^2}{m_{\phi_n}^2 - s - im_{\phi_n}\Gamma_{\phi_n}^j},$$

$$\Gamma_{\phi_n}^j = \frac{m_{\phi_n}^2}{s} \left( \frac{s - 4m_j^2}{m_{\phi_n}^2 - 4m_j^2} \right)^{\frac{3}{2}} \Gamma_{\phi_n},$$

$$j = K^+, K^0$$

(18)

were used for $\phi_n$, the radial excitations of $\phi$, and the GS Breit-Wigner functions (Eq.(2)) were used for $\rho_n$. The parameters $\beta_j^K$, $j = \rho, \omega, \phi$, were calculated from Eq.(15) using fitted $e^K$ parameter. The results of the fits are summarized in Tab. III and in Figs. 3 and 4. The high energy behaviour of both form factors is completely driven by the CLEO [33] measurement.

Following [32], i.e. assuming isospin symmetry, one arrives at the following predictions for the branching ratio of the $\tau$-lepton decay into $K^-K^0\nu_{\tau}$

$$Br(\tau^- \to K^-K^0\nu_{\tau}) = \left(0.158 \pm 0.16\right) \cdot 10^{-3}$$

(20)

and are found to be reasonably consistent.

Within the same assumptions one can predict the $K^-K^0$ invariant mass distribution and compare it (see Fig. 5) with existing CLEO data [55]. As evident from Fig. 5 both models give very similar predictions and both agree with the data. Thus we conclude that within the current experimental accuracy, which is, however, very poor, isospin symmetry works well and the details of the models do not play any role in its tests.

IV. MONTE CARLO IMPLEMENTATION OF $K^+K^-$ AND $K^0\bar{K}^0$

The event generator PHOKHARA has been extended to generate $K^+K^-$ and $K^0\bar{K}^0$ final states. In this section we present the implementation and results for the region below the narrow resonances $J/\psi$ and $\psi(2S)$. Charged kaons have been implemented in the same way as the

TABLE II: Parameters of the kaon form factors and results of the fit to the data. Masses and widths are given in MeV. The column 'Fit(1)' (Fit(2)) contains the values of the constrained (unconstrained) fits.
We assume that in the vacuum polarization contributions as well as the φ polarization contributions are not present. We explicitly indicate the vacuum correction given by PHOKHARA reads

\[ \Phi(\mathcal{F}) \]

even for minimum of B factories one expects hundreds of events. The radiative return, as implemented now in PHOKHARA, receives contributions from a multitude of amplitudes shown in Fig. 5. The notation introduced in this figure also applies to the narrow resonance amplitudes. Below we list the formulae for \( \mu^+\mu^- \), \( \pi^+\pi^- \), \( K^+K^- \) and \( K^0\bar{K}^0 \). For the \( K^0\bar{K}^0 \) amplitude FSR emission is not present. We explicitly indicate the vacuum polarization contributions as well as the φ contribution. We assume that in the vacuum polarization \( J/\psi, \psi(2S) \) and φ were not accounted for. The differential cross section given by PHOKHARA reads

\[
\frac{d\sigma}{dQ^2} = |M_{\gamma_1,LOISR} \cdot C_{R,P}^V(Q^2) + M_{\gamma_1,LOFSR} \cdot C_{R,P}(s)|^2 d\Phi_1 + |M_{\gamma_2,ISR} \cdot C_{R,P}^V(Q^2)|^2 d\Phi_2 + 2 \text{Re}(M_{\gamma_1,LOISR} \times M_{\gamma_1,LOSR}^\dagger) \cdot |C_{R,P}^V(Q^2)|^2 d\Phi_1 + |M_{\gamma_1,ISR} \cdot C_{R,P}^V((Q + k_{\gamma_1})^2)|^2 d\Phi_2 + 2 \text{Re}(M_{\gamma_1,LOISR} \times M_{\gamma_1,LOSR}^\dagger) \cdot |C_{R,P}^V(Q + k_{\gamma_1})|^2 d\Phi_1 + |M_{\gamma_1,ISR} \cdot C_{R,P}^V((Q + k_{\gamma_1})^2)|^2 d\Phi_2 + 2 \text{Re}(M_{\gamma_1,LOISR} \times M_{\gamma_1,LOSR}^\dagger) \cdot |C_{R,P}(s)|^2 d\Phi_1 \]

photon(s) in the final state with all statistical factors
and narrow resonances into P kaon form factor, hence
tributions to the kaon pair production are included in the
neutral kaon form factor (see [25] for details). The
phases are essentially not known and we use 100
the numerical values in the next section.

every the amplitude can be found in [25] (see [27] for simi-
tral kaon couplings to the narrow resonances is almost
and

\[ C_{\mu_1,\mu_2}(s) = \frac{1}{1 - \Delta(s)} \left\{ \begin{array}{c} 3 \frac{\Gamma_{\gamma}^\phi}{\alpha m_{\phi}} \times \text{BW}_{\phi}(s) \delta_P \vspace{1em} \\
+ C_{J/\psi,\mu_1,\mu_2}(s) + C_{\psi(2S),\mu_1,\mu_2}(s) \end{array} \right. \]

(22)

\[ C_{\mu_1,\mu_2}(s) = \frac{3 \sqrt{s}}{\alpha} \frac{\Gamma_{\gamma}^R}{s - M_{\gamma}^2 + i\Gamma_{\gamma}^R M_{\gamma}} \]

(23)

and \( d\Phi_1 \) (\( d\Phi_2 \)) denote the phase space with one (two)
photon(s) in the final state with all statistical factors included.

For \( P = \mu \) and \( P = \pi \), \( c^{\mu_1}_{\mu_2} = 0 \) (no direct decay of the
narrow resonances into \( \mu^+\mu^- \) and \( \pi^+\pi^- \)), while \( \delta_P = 0 \)
for \( P = K \) and \( \delta_P = 1 \) for \( P = \mu \) and \( P = \pi \). The \( \phi \)
contributions to the kaon pair production are included in the
kaon form factor, hence \( \delta_K = 0 \). The notation and the
detailed description of the narrow resonance contribution
to the amplitude can be found in [25] (see [27] for simi-
lar studies). From [25] we also take \( |e_{K^+}^{J/\psi}| = 1.27 \pm 0.32 \)
and \( |e_{K^+}^{\psi(2S)}| = 2.94 \pm 0.99 \). The information on the neutral
kaon couplings to the narrow resonances is almost
nonexistent and we use the lower limits of \( |e_{K^+}^{J/\psi}| = 2.81 \),
\( |e_{K^+}^{\psi(2S)}| = 5.35 \), which correspond to the upper limit on
the neutral kaon form factor (see [25] for details). The
phases are essentially not known and we use 100° to
obtain the numerical values in the next section.

VI. THE IMPLEMENTATION OF NARROW RESONANCES INTO THE MONTE CARLO EVENT GENERATOR PHOKHARA

The tests of the ISR part of the implementation of the
narrow resonances where straightforward and followed

the standard tests we perform for each new channel [14–
20, 22]. The comparisons were made with the analytic
formulae of [53] separately for one and two photon emis-
ion. The precision of the comparisons was at the level of
a small fraction of a per mill, proving the technical pre-
icision of the program at that level. The independence of
the results on the separation parameter between soft pho-
ton, calculated analytically and hard photon, generated
by means of the Monte Carlo method, was also tested
with that precision.

The implementation of the NLO FSR part is more
tricky. The analytic formulae used in [16, 18] for soft photon
contributions are still valid, which we have checked
numerically with the precision of 0.02%. However if one
chooses the separation parameter between soft and hard
part at the usual value \( w = 10^{-4} \), which corresponds to
the photon energy \( E_{\gamma} = 1 \) MeV for \( \sqrt{s} = 10 \) GeV,
the ‘soft’ integral receives contributions from the whole

FIG. 7: (color online) Comparison of IFSNLO and ISRNLO distributions with angular cuts.

\[ e^+e^- \rightarrow K^+K^-\gamma(\gamma) \]

\[ \frac{d^2 \sigma(1FSNLO)}{dQ^2} \]

\[ \frac{d^2 \sigma(1ISRNLO)}{dQ^2} \]

\[ \sqrt{s} = 10.52 \text{ GeV} \]

\[ 30^\circ < \theta^- < 160^\circ \]

\[ 30^\circ < \theta^+ < 50^\circ \]

\[ \delta_T = 0 \]

\[ \Delta(s) = 1 \]

\[ C_{\mu_1,\mu_2}(s) = \frac{1}{1 - \Delta(s)} \left\{ \begin{array}{c} 3 \frac{\Gamma_{\gamma}^\phi}{\alpha m_{\phi}} \times \text{BW}_{\phi}(s) \delta_P \\
+ C_{J/\psi,\mu_1,\mu_2}(s) + C_{\psi(2S),\mu_1,\mu_2}(s) \end{array} \right. \]

(22)

\[ C_{\mu_1,\mu_2}(s) = \frac{3 \sqrt{s}}{\alpha} \frac{\Gamma_{\gamma}^R}{s - M_{\gamma}^2 + i\Gamma_{\gamma}^R M_{\gamma}} \]

(23)

\[ |M_{\gamma,LOSR} + M_{\gamma,LOSR}^2| \]

\[ |M_{\gamma,ISR}^2| \]

\[ 2 \text{ Re}(M_{\gamma,LOSR} \times M_{\gamma,LOSR}) \]

\[ |M_{\gamma,ISR,FSR}^2| \]

\[ 2 \text{ Re}(M_{\gamma,LOSR} \times M_{\gamma,LOSR}) \]

\[ |M_{\gamma,ISR,FSR}^2| \]

\[ 2 \text{ Re}(M_{\gamma,LOSR} \times M_{\gamma,LOSR}) \]

FIG. 8: (color online). The contributions to the radiative return cross section included in PHOKHARA. Label ‘1’ at a photon line means that the photon is hard.
resonance region, as a consequence of the small width ($\Gamma_{J/\psi} = 93.4$ keV). For a cutoff of $10^{-4}$ the part of the matrix element, which multiplies the soft emission factor is rapidly varying and the basic assumption underlying the whole approach, that the soft emission can be integrated analytically with the multiplicative remainder being constant, is no longer valid. Pushing the value of the cutoff to an extremely small value, say $10^{-7}$, solves this problem. However, single-photon emission is not an adequate description for such soft photons and in principle one should use exponentiation. From the technical side this is reflected in the appearance of negative weights. Inclusion of YFS-like multi-photon production would allow to cure this problem. However since this would amount to completely restructuring our Monte Carlo generator, we have adopted a simpler approach, which gives correct distributions, when convoluted with an energy resolution typical for a detector at a $\phi$- or $B$-meson factory.

Due to the finite detector resolution one never observes the true distribution of the events, but the one convoluted with the detector resolution function. This increase of the effective width by about a factor hundred is sufficient to cure the problem. For a cutoff of $10^{-4}$ the distribution remains smooth and we can produce the unweighted events sample. The result will, as expected, depend on the resolution of the detector. To check if this is true for the realistic energy resolution of the BaBar detector [24]...
of $14.5\text{ MeV}$ we have compared the muon invariant mass distributions obtained with $w = 10^{-4}$ and $w = 10^{-7}$, smeared with a Gaussian distribution with a standard deviation of $14.5\text{ MeV}$. Even if the non-smeared distributions are completely different, as shown in Fig. [3] the smeared distributions agree within 2 per mill as shown in Fig. [11]. This 2 per mill is the intrinsic error coming from the method we use, but the generator should be accurate enough for any practical purposes.

It is interesting to observe (Fig. [11]) that the FSRNLO contributions fill completely the interference dip, still visible if only ISR corrections are taken into account. Thus the absence of the dip in the observed invariant mass distribution is not only the effect of the detector smearing.

The huge FSRNLO corrections seen in Fig. [11] are washed out if one looks at the detector smeared distributions shown in Fig. [12]. The corrections are seen more accurately in Fig. [13] where the relative difference is shown. The FSRNLO corrections cannot be neglected if one aims at a precision better than 10%, unless one considers only the integral over the whole resonance region (together with the side bands as shown in Fig. [12]). In the integrated cross section a large part of the corrections cancel ($\sigma_{\text{ISR}} = 6.901\text{ pb}$, $\sigma_{\text{FSR}} = 6.954\text{ pb}$).

Identical tests were performed for the pion pair production with identical conclusions, so we do not present them here.

VII. SUMMARY

New parametrizations of the pion and kaon form factors, based on the "dual QCD model", are presented which are derived from a fit to a combination of old measurements and more recent experimental results in the energy region above the $\rho$-resonance. These form factors and the results of a recent analysis of the direct hadronic coupling of $K\bar{K}$ to $J/\psi$ and $\psi(2S)$ are incorporated in the Monte Carlo generator PHOKHARA which is now also adapted to the simulation of narrow resonances, including the effects of ISR and FSR in NLO.
