On the number of non-isomorphic subspaces of a Banach space.

Valentin Ferenczi and Christian Rosendal

December 2001

Abstract

We study the number of non-isomorphic subspaces of a given Banach space. Our main result is the following: let $X$ be a Banach space with an unconditional basis $\{e_i\}_{i \in \mathbb{N}}$; then either there exists a perfect set $P$ of infinite subsets of $\mathbb{N}$ such that for any two distinct $A, B \in P$, $[e_i]_{i \in A} \not\cong [e_i]_{i \in B}$, or for a residual set of infinite subsets $A$ of $\mathbb{N}$, $[e_i]_{i \in A}$ is isomorphic to $X$, and in that case, $X$ is isomorphic to its square, to its hyperplanes, uniformly isomorphic to $X \oplus [e_i]_{i \in D}$ for any $D \subset \mathbb{N}$ and to a denumerable Schauder decomposition into uniformly isomorphic copies of itself.

The starting point of this article is the so called ”homogeneous space problem”, due to S. Banach. It has been solved at the end of last century by W.T. Gowers ([2], [3]), R. Komorowski- N. Tomczak ([7], [8]) and W.T. Gowers- B. Maurey ([4]); see e.g. [10] for a survey. Recall that a Banach space is said to be homogeneous if it is isomorphic to all its (infinite-dimensional closed) subspaces. The previously named authors showed that $l_2$ is the only homogeneous Banach space. A very natural question was posed to us by G. Godefroy: if a Banach space is not isomorphic to $l_2$, then how many mutually non-isomorphic subspaces must it contain (obviously, at least 2). In this article, we concentrate on spaces with a basis and subspaces of it spanned by subsequences. We shall also be interested in the relation of equivalence of basic sequences. By ”many” we shall mean the Cantor concept of cardinality, and sometimes finer concepts from the theory of classification of equivalence relations in descriptive set theory.

1 Basic notions about basic sequences.

Let $X$ be some separable Banach space and $\{e_i\}_\omega$ a non zero sequence in $X$. We say that $\{e_i\}_\omega$ is a basis for $X$ if any vector $x$ in $X$ can be uniquely written as a norm
convergent series \( x = \sum_\omega a_i e_i \). In that case the functionals \( e^*_k(\sum_\omega a_i e_i) := a_k \) are in fact continuous, as are the projections \( P_n(\sum_\omega a_i e_i) := \sum_{i=0}^n a_i e_i \) and furthermore their norms are uniformly bounded \( \sup_\omega \| P_n \| < \infty \); the supremum is called the basic constant of \( \{ e_i \}_\omega \) and is denoted by \( bc(\{ e_i \}_\omega) \). If \( \{ e_i \}_\omega \) is some non zero sequence that is a basis for its closed linear span, written \( [e_i]_\omega \), we say that it is a basic sequence in \( X \) and its basic constant is defined as before. The property of \( \{ e_i \}_\omega \) being a basic sequence can also equivalently be stated as the existence of a constant \( K \geq 1 \) such that for any \( n \leq m \) and \( a_0, a_1, \ldots, a_m \in \mathbb{R} \):

\[
\| \sum_{i=0}^n a_i e_i \| \leq K \| \sum_{i=0}^m a_i e_i \|
\]

The infimum of such \( K \) will then be the basic constant \( bc(\{ e_i \}_\omega) \). Suppose furthermore that for any \( x = \sum_\omega a_i e_i \) the series actually converges unconditionally, i.e. for any permutation \( \sigma \) of \( \omega \) the series \( \sum_\omega a_\sigma(i) e_\sigma(i) \) converge to \( x \), then the basic sequence is said to be unconditional. We note that a classical result of Dvoretzky and Rogers states that in an infinite dimensional Banach space, in contradiction to \( \mathbb{R} \), there is always an unconditionally convergent series that does not converge absolutely (i.e. \( \sum_\omega \| x_i \| = \infty \)). Again being an unconditional basis for some closed subspace (which will be designated by ‘unconditional basic sequence’) is equivalent to there being a constant \( K \geq 1 \), such that for all \( n \) and \( A \subset \{ 0, \ldots, n \} \), \( a_0, \ldots, a_n \in \mathbb{R} \):

\[
\| \sum_{i \in A} a_i e_i \| \leq K \| \sum_{i=0}^n a_i e_i \|
\]

We will in general only work with normalized basic sequences, i.e. \( \| e_i \| \equiv 1 \), which always can be obtained by taking \( e'_i := \frac{e_i}{\| e_i \|} \). Moreover it will often be useful to to suppose the basis monotone, that is that the above inequalities holds for \( K = 1 \). This can also be got by renorming the space by

\[
\| \sum_\omega a_i e_i \| := \sup_\omega \| \sum_{i=0}^n a_i e_i \| \leq bc(\{ e_i \}_\omega) \| \sum_\omega a_i e_i \|
\]

in the case of a (maybe) conditional basis and

\[
\| \sum_\omega a_i e_i \| := \sup_{<,> \in \{-1,1\}^\omega} \| \sum_\omega \epsilon_i a_i e_i \| \leq bc(\{ e_i \}_\omega) \| \sum_\omega a_i e_i \|
\]

for an unconditional basis.

Two sequences \( (e_i) \) and \( (f_i) \) are said to be equivalent if there exists \( C \) and \( a, b \) with \( ab \leq C \) such that \( (1/a)\| \sum \lambda_i e_i \| \leq \| \sum \lambda_i f_i \| \leq b \| \sum \lambda_i e_i \| \), in which case they are said to \( C \)-equivalent. For basic sequences, this is equivalent to saying that for
any choice of reals \((\lambda_i)_{i \in \mathbb{N}}\), \(\sum \lambda_i e_i\) converges if and only if \(\sum \lambda_i f_i\) converges. We shall write \((e_i) \approx (f_i)\) to mean that \((e_i)\) and \((f_i)\) are equivalent.

A space \(\mathcal{Y}\) is isomorphic to \(\mathcal{Z}\) if there is a bijective continuous linear map \(T\) from \(\mathcal{Y}\) onto \(\mathcal{Z}\) such that \(T^{-1}\) is also continuous. They are \(C\)-isomorphic if this happens for some \(T\) such that \(\|T\|\|T^{-1}\| \leq C\). The Banach-Mazur distance between \(\mathcal{Y}\) and \(\mathcal{Z}\), denoted by \(d_{BM}(\mathcal{Y}, \mathcal{Z})\) is defined as the infimum of the \(C\)'s such that \(\mathcal{Y}\) and \(\mathcal{Z}\) are \(C\)-isomorphic. We shall write \(\mathcal{Z} \simeq \mathcal{Y}\) to mean that \(\mathcal{Y}\) and \(\mathcal{Z}\) are isomorphic, \(\mathcal{Z} \simeq K\mathcal{Y}\) to mean that they are \(K\)-isomorphic.

2 Models of separable Banach spaces and their basic sequences.

To study separable Banach spaces by topological means we need in some way to make a space out of them. So we turn to descriptive set theory for the basic tools. Let \(\mathfrak{X}\) be a Polish space and \(F(\mathfrak{X})\) denote the set of closed subsets of \(\mathfrak{X}\). We endow \(F(\mathfrak{X})\) with the following \(\sigma\)-algebra that renders it a standard Borel space. The generators are the following sets, where \(U\) varies over the open subsets of \(\mathfrak{X}\):

\[
\{ F \in F(\mathfrak{X}) \mid F \cap U \neq \emptyset \}
\]

The resulting measurable space is called the Effros Borel space of \(F(\mathfrak{X})\).

A theorem due to Kuratowski/Ryll-Nardzewski states that there is a sequence of Borel functions \(d_n : F(\mathfrak{X}) \rightarrow \mathfrak{X}\), such that for nonempty \(F \in F(\mathfrak{X})\) the set \(\{ d_n(F) \}\) is dense in \(F\). Supposing now that \(\mathfrak{X}\) is a separable Banach space, we can in a Borel manner express that \(F \in F(\mathfrak{X})\) is a linear subspace of \(\mathfrak{X}\):

\[
0 \in F \land \forall n, m \forall p, q \in \mathbb{Q}(pd_n(F) + qd_m(F) \in F)
\]

Here we have in all honesty to admit that we use the fact that the relations \(F_0 \subset F_1\) and \(x \in F\) are Borel in \(F(\mathfrak{X})^2\) and \(\mathfrak{X} \times F(\mathfrak{X})\) respectively.

But then it is possible to construct a standard Borel space consisting of all separable (real if you wish) Banach spaces, simply take any isometrically universal separable Banach space (to be definite take \(C(2^\omega)\)) and let \(\mathfrak{A}\) be the set of closed linear subspaces of it. Call \(\mathfrak{A}\) the Borel space of separable Banach spaces.

There is now a space in which we can express the relations of (linear) isomorphism, isometry, etc. and we will see that their descriptive complexity are as they should be, eg. analytic for isomorphism.

If we restrict ourselves to certain types of subspaces, the situation is far less involved. Spaces spanned by subsequences of a given basis can be identified with \(2^\omega\).
Also, following Gowers in [2],[3], it is natural to see the set $\mathbb{b}$ of normalized block sequences of a given basis as a closed subset of $\mathbb{X}$ equipped with the product of the norm topology; as expected, $\approx$ is Borel in $\mathbb{b}^2$. The associated canonical injection from $2^\omega$ (resp. $\mathbb{b}$) into $\mathbb{A}$ is Borel.

Going back to the notion of isomorphism, we see that it is indeed analytic: For $\mathbb{X}, \mathbb{Y} \in \mathbb{A}$ we have $\mathbb{X} \cong \mathbb{Y}$ iff

$$\exists x \exists y \ (x \approx y \land \forall n \ x_n \in \mathbb{X} \land \forall n \ y_n \in \mathbb{Y} \land \forall n (U_n \cap \mathbb{X} \neq \emptyset \rightarrow \exists m \ x_m \in U_n)$$

$$\land \forall n (U_n \cap \mathbb{Y} \neq \emptyset \rightarrow \exists m \ y_m \in U_n).$$

Here $\{U_n\}_{n \in \mathbb{N}}$ is a basis for the topology on $C(2^\omega)$.

Our first result concerns equivalence of subsequences (resp. block-bases) of a given basis.

3 Counting the number of nonequivalent blockbases.

Until now we have only been looking at Cantor’s concept of cardinality, but there is also a newer and finer one stemming from descriptive set theory. It allows us to distinguish between different levels of $2^\omega$ according to their complexity. For the definition:

**Definition 1** Let $E \subset \mathbb{X}^2$ and $F \subset \mathbb{Y}^2$ be equivalence relations on standard Borel spaces $\mathbb{X}$ and $\mathbb{Y}$. We say that $E$ is Borel reducible to $F$ ($E \leq_B F$) if there is a Borel function $\phi : \mathbb{X} \rightarrow \mathbb{Y}$ such that $\forall x, y \in \mathbb{X} \ xEy \leftrightarrow \phi(x)F\phi(y)$. $E$ is Borel bireducible with $F$ ($E \sim_B F$) if both $E \leq_B F$ and $F \leq_B E$.

The definition has not much interest unless $\mathbb{X}$ and $\mathbb{Y}$ are uncountable and $E$ and $F$ have uncountably many classes. Furthermore it is usually supposed that the equivalence relations are of some bounded complexity, eg. Borel or analytic.

Being given some normalized basic sequence $\{e_i\}_{i \in \mathbb{N}}$ in a separable Banach space $\mathbb{X}$, we can look at the set of its subsequences as a subspace of $2^\omega$, just take away the countable set $FIN$ and identify a subsequence with its set of indices. $2^\omega \setminus FIN$ is still a Polish space (though now noncompact) under the usual topology.

Note that equivalence of such normalized basic sequences, $\approx$ induces a Borel equivalence relation on $2^\omega \setminus FIN$.

An important measure of complexity is the following equivalence relation $E_0$, it is the minimum (up to $\sim_B$) Borel equivalence relation $\leq_B$ above identity on Polish spaces and is defined on $2^\omega$ as follows:

$$\alpha E_0 \beta : \equiv \exists n \in \mathbb{N} \ \forall m \geq n \ \alpha_m = \beta_m$$
Proposition 2 Let $\mathcal{X}$ be a Banach space with a basis $\{e_i\}_{i \in \mathbb{N}}$.

- Either $\{e_i\}_{i \in \mathbb{N}}$ is perfectly homogeneous, i.e. equivalent to all of its normalized block basic sequences (and therefore equivalent to the standard unit basis in some $l_p$, $1 \leq p < \infty$ or $c_0$), or $E_0 \leq_B \approx |\mathbb{bb}|$;

- Either $\{e_i\}_{i \in \mathbb{N}}$ is subsymmetric, i.e. equivalent to all of its subsequences, or $E_0 \leq_B \sim$.

Proof: We show only the first part as the proof of the second is essentially the same.

Assume that $\mathcal{X}$ has at least two non-equivalent normalized block sequences, $(x_i)$ and $(y_i)$. Then $(x_i)$ and $(y_i)$ are not 2-equivalent, so there exists $I_1$ an interval of integers such that $(x_i)_{i \in I_1}$ and $(y_i)_{i \in I_1}$ are not 2-equivalent. Also for any $k$, $(x_i)_{i>k}$ and $(y_i)_{i>k}$ are not equivalent so there exists $k < I_2 \subset \mathbb{N}$ such that $(x_i)_{i \in I_2}$ and $(y_i)_{i \in I_2}$ are not 4-equivalent. Without loss of generality, we may assume that $\text{supp}(x_i, i \in I_2) \cup \text{supp}(y_i, i \in I_2) > \text{supp}(x_i, i \in I_1) \cup \text{supp}(y_i, i \in I_1)$ Repeating this, we get a sequence of successive intervals $I_k$ such that $(x_i)_{i \in I_k}$ and $(y_i)_{i \in I_k}$ are not $2^k$-equivalent.

For any $\alpha \in 2^\omega$, let $f(\alpha)$ be the unique block basis defined by the set of vectors $\{f_i| i \in \cup_{j \in \mathbb{N}} I_j\}$, with $f_i = x_i$ if $i \in I_j$ with $\alpha(j) = 0$, $f_i = y_i$ if $i \in I_j$ with $\alpha(j) = 1$; clearly, $f(\alpha)$ is equivalent to $f(\beta)$ iff $\alpha E_0 \beta$ and the map is Borel (even continuous). $\square$

Let us mention that in the case where $E_0$ Borel reduces to an analytic equivalence relation this latter can have no analytic section. That is, there can be no analytic set intersecting every equivalence class in exactly one point. So in particular the above result says that if there is more that one class, then the relation is rather complicated, and cannot in fact be classified in a Borel manner by real numbers. Also, we refer to the forthcoming [1] for discussion about isomorphism on $\mathbb{bb}$.

3.1 Subsequences of a basis

3.1.1 Classical Ramsey type results.

We first mention that classical Ramsey type results can be proved in the case where there are countably many classes of isomorphism.

Lemma 3 For any $n$, there exist a constant $c(n) = 1 + n(2^{n+1} + 1)^2$, such that for any Banach space $\mathcal{X}$, all $n$-codimensional subspaces of $\mathcal{X}$ are $c(n)$ isomorphic.

Proof: We are not interested in finding the best constant. We prove that for any Banach space $\mathcal{X}$, any $n$-codimensional subspace $\mathfrak{Z}$ of $\mathcal{X}$, $d_{BM}(\mathcal{X}, \mathfrak{Z} \oplus 1_{l_2^n}) \leq$
In this proof, we think of sets $A$ and $\mathcal{Y}$ as the basic open set of all $K$ and $\mathcal{Y}$, so $\mathcal{Y}$ (resp. $\mathcal{Y}'$) is $\sqrt{n}(2^{n+1} + 1)$-isomorphic to $\mathcal{Y} \oplus_1 l^2_2$ for all $\epsilon > 0$, and $d_{BM}(\mathcal{Y}, \mathcal{Y}') \leq n(2^{n+1} + 1)^2$.

So let $\mathcal{X}$ be a Banach space and $\mathcal{Z}$ be $n$-codimensional in $\mathcal{X}$. By induction, there exists a projection $P$ on $\mathcal{Z}$ of norm smaller than $2^n + \epsilon$. Let $F = (Id - P)(\mathcal{X})$. Then using $P$ one shows that $\mathcal{X} = \mathcal{Z} \oplus F$ is $2^{n+1} + 1 + 2\epsilon$-isomorphic to $\mathcal{Z} \oplus F$. By classical results, $F$ is $\sqrt{n}$-isomorphic to $l^2_2$, and it follows that $\mathcal{X}$ is $\sqrt{n}(2^{n+1} + 1 + 2\epsilon)$-isomorphic to $\mathcal{Z} \oplus l^2_2$.

To spark confusion we will identify several different objects; namely the space $[e_i]_{i \in A}$ for some subset $A \subset \mathbb{N}$ with the characteristic function $\chi_A$ seen as a point in the Cantor space $2^\omega$ which we again simply identify with the subset $A$ of $\mathbb{N}$. The subspaces spanned by subsequences are therefore equipped with the compact Polish topology inherited from $2^\omega$. We denote by $A \cong B$ the fact that the corresponding Banach spaces are linearly isomorphic. If we see this relation as an equivalence relation between the points in the Effros Borel space of closed linear subspaces of $C(2^\omega)$ it is analytic, and furthermore the function associating to $A \subset \mathbb{N}$ the space (or point) in the Effros Borel space is Borel. So, as noted at the end of first section, we have an induced analytic equivalence relation, denoted by $\cong$, on $2^\omega$. For $K \geq 1$, write $A \cong_K B$ to mean that the corresponding spaces are $K$-isomorphic, so that $\cong$ is the union of the $\cong_K$, $K \in \mathbb{N}$. Recall that for $u = (u(0), \ldots, u(k)) \in 2^<\omega$, $N_u$ denotes the basic open set of all $A \in 2^\omega$ such that $i \in A$ iff $u(i) = 1$, $\forall i \leq k$.

**Proposition 4** Let $\mathcal{X}$ be a Banach space with a basis $\{e_i\}_{i \in \mathbb{N}}$. If $\mathcal{X}$ has countably many classes of isomorphism generated by subsequences of the basis then there exists $K$ and $A \subset \mathbb{N}$ such that $[e_i]_{i \in B} \cong_K [e_i]_{i \in A}$ for all $B \subset A$.

**Proof:** In this proof, we think of sets $A$ as increasing sequences of integers. For each $n$, let $E_n \subset \mathbb{N}$ be a representative in the $n$-th $\cong$ class. Say that $A$ belongs to $\mathcal{A}_{m,n}$ if $A \cong_m E_n$; fix furthermore a bijection $k \mapsto (m_k, n_k)$ between $\mathbb{N}$ and $\mathbb{N}^2$.

Assume a Banach space $\mathcal{X}$ contradicts the proposition and apply the infinite Ramsey theorem. No subset of $\mathbb{N}$ has all its subsets in $\mathcal{A}_{m_0,n_0}$, so there exists $A_0 \subset \mathbb{N}$ so that no subset of $A_0$ is in $\mathcal{A}_{m_0,n_0}$. Let $k_0$ be an integer in $A_0$. No subset $A$ of $A_0$ after $k_0$ is such that $\{k_0\} \cup A$ has all its subsets in $\mathcal{A}_{m_1,n_1}$: otherwise, any subset $\{b_0 < b_1 < \ldots\}$ of $A$, spans a space which is $c(1)$-isomorphic to the span of $\{k_0 < b_1 < \ldots\}$, so is $c(1)m_0$ isomorphic to $E_{n_0}$, a contradiction. So some subset $A_1$ of $A_0$ after $k_0$ is such that $\{k_0\} \cup A$ belongs to $\mathcal{A}_{m_1,n_1}$ for no $A \subset A_1$. Choose $k_1$ in $A_1$. Repeating this, define a decreasing sequence $A_n$ and an increasing sequence $k_n$ with $k_i$ in $A_i$, to get a set $K = \{k_p, p \in \mathbb{N}\}$ belonging to no $\mathcal{A}_{m,n}$. This should be sufficient to convince you. \qed
The example of $l_1 \oplus l_2$ proves that the isomorphism class in this proposition need not contain $\mathcal{X}$, nor contain "most" subspaces of $\mathcal{X}$, in fact, we shall see that the class of $l_1$ (resp. $l_2$) is meager in the standard topology associated to the space.

4 Banach spaces with unconditional basis isomorphic to their squares.

Let $\mathcal{X}$ be a Banach space with a basis $\{e_i\}_{i \in \mathbb{N}}$. We will study the linear-isomorphism classes of spaces spanned by subsequences (finite and infinite) of this basis by using Baire category.

As the finite subsets of $\mathbb{N}$ are fully characterized up to $\cong$ by their cardinality we will often forget about them, therefore we want a name for them, so we remember what we are forgetting. Consequently let $FIN$ be the Frechet ideal of finite subsets of $\mathbb{N}$.

Also other relations on $2^{\omega}$ will be useful. First note that the Cantor space is an Abelian Polish group under the action of symmetric difference $\Delta$, as such the identity element is $\emptyset$ and each element is its own inverse. Therefore not only $\cong$ but also the relations:

$$A \sim_1 B :\equiv A \cong \complement B$$
$$A \sim_2 B :\equiv \complement A \cong \complement B$$

are analytic in $2^{\omega}$.

**Theorem 5** (Kuratowski/Mycielski) Let $\mathcal{X}$ be a perfect Polish space, and $R$ be a relation on $\mathcal{X}$ meager in $\mathcal{X}^2$. Then there exists a homeomorphic copy $\mathcal{C}$ of the Cantor space such that $\forall x, y \in \mathcal{C}$ with $x \neq y$ we have $\neg xRy$.

Suppose now that $\cong$, $\sim_1$ and $\sim_2$ all are meager in the product $2^{\omega} \times 2^{\omega}$, then so is their union and the theorem above gives us a Cantor set $\mathcal{C}$ avoiding the three relations. Now by taking away the countable set (possibly finite or empty) of finite sets in $\mathcal{C}$ and going to a further subset, we can suppose that $\mathcal{C} \cap FIN = \emptyset$.

Following Kalton we say that the basis $\{e_i\}_{i \in \mathbb{N}}$ is countably primary if there is a countable list $E_0, E_1, E_2, \ldots$ of Banach spaces such that if $A \subset \mathbb{N}$ then for some $n$ either $[e_i]_{i \in A} \cong E_n$ or $[e_i]_{i \notin A} \cong E_n$. It is now easy to see that our space cannot be countably primary, for take two subsets of $\mathbb{N}$, $A \neq B, A, B \in \mathcal{C}$, such that they have the same $E_n$ associated, i.e. either $A \cong E_n \cong B$, $A \cong E_n \cong \complement B$, $\complement A \cong E_n \cong B$ or $\complement A \cong E_n \cong \complement B$. It should be evident for the reader taking the pains of unraveling our definitions that we get a minor contradiction here.
Going in the other direction we wish to see what we get from the fact that some of the three relations are nonmeager in the product. First we note that a Fubini type theorem is true also in Baire category:

**Theorem 6** (Kuratowski/Ulam) Let $\mathcal{Y}$ be a Polish space and $\mathcal{D}$ a subset of the square having the Baire property, then $\mathcal{D}$ is nonmeager $\equiv \exists^* x \exists^* y(x, y) \in \mathcal{D} \equiv \exists^* y \exists^* x(x, y) \in \mathcal{D}$

Here $\exists^* x P(x)$ signifies the existence of a nonmeager set of $x$ such that $P(x)$. Applying this to the above relations we get the following:

\[ \cong \text{nonmeager in } 2^\omega \times 2^\omega \Rightarrow \exists A \in 2^\omega \exists^* B \in 2^\omega A \cong B \]

\[ \sim_1 \text{nonmeager in } 2^\omega \times 2^\omega \Rightarrow \exists B \in 2^\omega \exists^* A \in 2^\omega A \cong \complement B \]

\[ \Rightarrow \exists C \in 2^\omega \exists^* A \in 2^\omega A \cong C \]

\[ \sim_2 \text{nonmeager in } 2^\omega \times 2^\omega \Rightarrow \exists A \in 2^\omega \exists^* B \in 2^\omega \complement A \cong B \]

\[ \Rightarrow \exists C \in 2^\omega \exists^* D \in 2^\omega C \cong D \]

So all of the three cases gives us a nonmeager isomorphism class $\mathcal{A}$ in $2^\omega$. Fix $B$ in $\mathcal{A}$ and for all $M \in \mathbb{N}$ denote by $\mathcal{A}_M$ the set $\{ A : A \cong_M B \}$. Then for some $M$ large enough in $\mathbb{N}$, $\mathcal{A}_M$ is nonmeager as well, and we intend to show that $\mathcal{A}_K$ for some $K \geq M$ (and therefore $\mathcal{A}$) is actually residual in the Cantor space.

Note that being a section of an analytic set $(\mathcal{A} = (\cong_M)_B) \mathcal{A}_M$ is itself analytic and has therefore the property of Baire. So as it is nonmeager it must be residual in an open set $U \subset 2^\omega$ and by going to a smaller open set we can suppose that $U$ is on the form $N_s$ for some finite sequence $s \in 2^{<\omega}$. There are for us two interesting features of $s$, its length and its cardinality. By the length, $|s|$, we denote its length as a sequence and by the cardinality, $\overline{s}$, is denoted the number of 1’s appearing in the sequence. We prove that $\mathcal{A}_K$ is residual for $K = Mc(2|s|)$.

Otherwise, let $t \in 2^{<\omega}$ be such that $\mathcal{A}_K$ is meager in $N_t$. Without loss of generality, assume $|t| \geq |s|$ and write $t = u \prec v$, with $|u| = |s|$. Then let $t' = t \prec s = u \prec v \prec s$ and $s' = s \prec v \prec u$. So $|t'| = |s'|$, $\overline{t'} = \overline{s'}$, and $\mathcal{A}_M$ is residual in $N_{s'}$ while $\mathcal{A}_K$ is meager in $N_{t'}$.

We have now a natural homeomorphism $\phi$ between the clopen sets $N_{s'}$ and $N_{t'}$; simply for an $A \in N_{s'}$ change the beginning from $s'$ to $t'$, i.e. $\phi(s' \prec \alpha) = t' \prec \alpha$, where $\chi_A = s' \prec \alpha$. By construction, $s' \prec \alpha$ and $t' \prec \alpha$ code subspaces of same codimension $2|s| - \overline{\overline{s}} - \overline{\overline{t}} \leq 2|s|$ of the space coded by $(1^{|s|}) \prec v \prec (1^{|s|}) \prec \alpha$ (here $1^n$ denotes the
length $n$ sequence of 1’s). By Lemma 3, it follows that $\phi(A) \equiv_{c(2)} A$. As $A_M$ is residual in $N_s$, it follows that $A_{c(2),M} \supset \phi(A_M)$ is residual in $N_{s'}$, a contradiction.

We now need a standard compactness result from descriptive set theory:

**Lemma 7** If $G$ is a residual subset of $2^\omega$, then there exists a partition $A_0, A_1, A_2, \ldots$ of $\mathbb{N}$ and subsets $B_i \subset A_i, i \in \mathbb{N}$ such that for any set $E \subset \mathbb{N}$ if $\exists i \in \mathbb{N}$ $E \cap A_i = B_i$ then $E \in G$

**Proof** : For $\mathcal{D}$ an open dense set in $2^\omega$ and $n \in \mathbb{N}$ there is $s \in 2^{<\omega}$ such that for any $t \in 2^n$ we have $N_{t \rightarrow s} \subset \mathcal{D}$.

This because we can enumerate $2^n$ as $\{t_1, t_2, \ldots, t_{2^n}\}$ and so due to the density and the fact that $\mathcal{D}$ is open there is some $s_1 \in 2^{<\omega}$ with $N_{t_1 \rightarrow s_1} \subset \mathcal{D}$.

Find $s_2 \in 2^{<\omega}$ with $N_{t_2 \rightarrow s_1} s_2 \subset \mathcal{D}$.

Again find $s_3 \in 2^{<\omega}$ with $N_{t_3 \rightarrow s_1} s_2 s_3 \subset \mathcal{D}$, etc.

Now put $s = s_1 s_2 \ldots s_{2^n}$ and we have our result.

Suppose that $G \supset \bigcap_{i \in \mathbb{N}} \mathcal{D}_i$ for open, dense sets $\mathcal{D}_i$.

- Take $s(0, 0)$ such that $N_{s(0, 0)} \subset \mathcal{D}_0$,
  put $n(1, 0) = |s(0, 0)|$.
- Take $s(1, 0)$ such that $N_{t \rightarrow s(1, 0)} \subset \mathcal{D}_0, \forall t \in 2^{n(1, 0)}$,
  put $n(0, 1) = n(1, 0) + |s(1, 0)|$.
- Take $s(0, 1)$ such that $N_{t \rightarrow s(0, 1)} \subset \mathcal{D}_1, \forall t \in 2^{n(0, 1)}$,
  put $n(2, 0) = n(0, 1) + |s(0, 1)|$.
- Take $s(2, 0)$ such that $N_{t \rightarrow s(2, 0)} \subset \mathcal{D}_0, \forall t \in 2^{n(2, 0)}$,
  put $n(1, 1) = n(2, 0) + |s(2, 0)|$.
- Take $s(1, 1)$ such that $N_{t \rightarrow s(1, 1)} \subset \mathcal{D}_1, \forall t \in 2^{n(1, 1)}$,
  put $n(0, 2) = n(1, 1) + |s(1, 1)|$.
- Take $s(0, 2)$ such that $N_{t \rightarrow s(0, 2)} \subset \mathcal{D}_2, \forall t \in 2^{n(0, 2)}$,
  put $n(3, 0) = n(0, 2) + |s(0, 2)|$,

etc.

- $A_i := \bigcup_{k \in \mathbb{N}} [n(i, k), n(i, k) + |s(i, k)|]$
- $B_i := \bigcup_{k \in \mathbb{N}} \{n(i, k) + m \mid (s(i, k))(m) = 1\}$

$\square$
Letting $A' := A_0, A'_1 := \bigcup_{i=1}^{\infty} A_i, B'_0 := B_0, B'_1 := \bigcup_{i=1}^{\infty} B_i$ we get: If $G$ is a residual set in $2^\omega$, then there is a partition $N = A'_0 \cup A'_1, A'_0 \cap A'_1 = \emptyset$ and sets $B'_i \subset A'_i, i \in 0, 1$, such that for any $D \subset N$, if either $D \cap A'_0 = B'_0$ or $D \cap A'_1 = B'_1$ we have $D \in G$.

We shall now assume the basis is unconditional. Apply this to $A$ and we see in particular that $B_0, B_1$ and $B_0 \cup B_1 \in A$. Now as $\{e_i\}_{i \in \mathbb{N}}$ is unconditional, we have for any pair of disjoint sets $C, D \subset N$ that $[e_i]_{i \in C} \oplus [e_i]_{i \in D} \cong [e_i]_{i \in C \cup D}$. Moreover $A$ being residual and $C$ a homeomorphism of $2^\omega$ there is some $C \subset N$ with $C, C \subset A$. So again abusing notation we calculate:

$$N \cong C \cup C \cong C \oplus C \cong B_0 \oplus B_0 \cong B_0 \oplus B_1 \cong B_0 \cup B_1 \cong B_0.$$ 

So $N$ belongs to the residual class $A$ and $[e_i]_{i \in \mathbb{N}}$ is isomorphic to $[e_i]_{i \in B_0}$ which is isomorphic to its square.

Without loss of generality assume $N$ belongs to $A_K$. Let $c$ be the constant of unconditionality of the basis. We denote by $\oplus_1$ the $l_1$-sum of Banach spaces.

Again take some arbitrary subset $D \subset N$, we have due to the fact that $A_0, A_1$ partition $N$:

$$N \oplus_1 D \cong_{K} (B_0 \cup B_1) \oplus_1 ((D \cap A_1) \cup (D \cap A_0)) \cong_{2C} B_0 \oplus_1 B_1 \oplus_1 (D \cap A_1) \oplus_1 (D \cap A_0) \cong_{2C} (B_0 \cup (D \cap A_1)) \oplus_1 (B_1 \cup (D \cap A_0)) \cong_K B_0 \oplus_1 B_1 \cong_K N$$

So spaces of the form $[e_i]_{i \in \mathbb{N}} \oplus_1 [e_i]_{i \in D}$ for any $D \subset N$ are $4C^2K^3$-isomorphic to $[e_i]_{i \in \mathbb{N}}$; and in particular $[e_i]_{i \in \mathbb{N}}$ is isomorphic to its hyperplanes.

Using also the complete version of the above lemma, we find $\bigcup_{i \in \mathbb{N}} B_i, B_0, B_1, B_2, \ldots \in A$. But $[e_i]_{i \in B_0}, [e_i]_{i \in B_1}, [e_i]_{i \in B_2}, \ldots$ gives (due to the unconditionality of the basis) an unconditional Schauder decomposition of $[e_i]_{i \in \bigcup_{i \in \mathbb{N}} B_i}$ and this latter is again isomorphic to $[e_i]_{i \in \mathbb{N}}$.

Summing up we have arrived at the following:

**Theorem 8** Let $X$ be a Banach space with an unconditional basis $\{e_i\}_{i \in \mathbb{N}}$, then either:

1. There exists a perfect set $P \subset 2^\omega$ of infinite subsets of $\mathbb{N}$ such that for any two distinct $A, B \in P$ we have that

   $$[e_i]_{i \in A} \not\cong [e_i]_{i \in B},$$

   $$[e_i]_{i \in A} \not\cong [e_i]_{i \in C},$$

   $$[e_i]_{i \in C} \not\cong [e_i]_{i \in B},$$

   or
(2) For $A$ in a residual subset of $2^\omega$, $[e_i]_{i \in A}$ is isomorphic to $X$; $X$ is isomorphic to its hyperplanes, to its square, uniformly isomorphic to $X \oplus [e_i]_{i \in D}$ for any $D \subset \mathbb{N}$ and to a denumerable unconditional Schauder decomposition into uniformly isomorphic copies of itself, $X \cong (\sum_{k \in \mathbb{N}} \oplus ([e_i]_{i \in B_k})).$

As we noticed earlier, (1) in our dichotomy implies that the least cardinal $\kappa$ such that the basis is $\kappa$-primary (with the obvious definition) is $2^\omega$, that is the trivial one.

The theorem improves on an earlier result by Kalton which gives (2) in case the unconditional basis is countably primary. His proof like the above used very little from Banach space theory, instead his setting was measure and probability theory [5].

As is easily seen from the proof, (1) can be strengthened considerably and to our purposes, in fact one can get a perfect set avoiding any countable list of relations of the form

$$[e_i]_{i \in A} \cong \phi(B)$$

where $\phi$ is a Borel function from $2^\omega$ to the Effros Borel space of closed linear subspaces of $C(2^\omega)$, that is the canonical space of separable Banach spaces. For example one could use Borel functions $\psi$ from $2^\omega$ to the space $\mathfrak{b}$ of normalized block sequences of some given basis, and one would avoid

$$[e_i]_{i \in A} \cong [\psi(B)].$$

Eg. we can force

$$[e_i]_{i \in A} \not\cong ([e_i]_{i \in B})^2$$
$$[e_i]_{i \in A} \not\cong ([e_i]_{i \in B})^3$$
$$[e_i]_{i \in A} \not\cong ([e_i]_{i \in B})^4$$

and so on. Or

$$[e_i]_{i \in A} \not\cong c_0([e_i]_{i \in B})$$

or whatever construction from B being reasonably explicit.

**Example 9** There is a certain sense in which the above result is optimal. For we might like to try to show that not only is some isomorphism class residual in $2^\omega$ but that it is all of $2^\omega \setminus \text{FIN}$. But this is easily seen to be false, for take the following basis for $l_1 \oplus l_2$:

$$\|a_0e_0 + a_1e_1 + \ldots + a_{2n+1}e_{2n+1}\| := |a_0| + |a_2| + \ldots + |a_{2n}| + \sqrt{a_1^2 + a_3^2 + \ldots + a_{2n+1}^2}$$

then there are exactly three isomorphism classes: $l_1$, $l_2$, and $l_1 \oplus l_2$ the first two being meager in $2^\omega$: Cause if $A \subset \mathbb{N}$, $A$ infinite, contains infinitely many even and odd numbers then $[e_i]_{i \in A} \cong l_1 \oplus l_2$, if it only contains finitely many even numbers then $[e_i]_{i \in A} \cong l_2$, and only finitely many odd numbers then $[e_i]_{i \in A} \cong l_1$. 

**Example 10** If we take the standard Haar basis for some $L_p([0,1])$, $1 < p < \infty$ then this is unconditional and in fact the only two spaces spanned by subsequences are $l_p$ and $L_p([0,1])$; so there are bases inducing exactly two isomorphism classes in $2^\omega \setminus FIN$. [9] Thm. 2.d.10.

**Example 11** Tsirelson’s space.

We take a look at the standard unit vector basis for the Tsirelson space. It has the following properties (here $\mathbb{N}^* = \mathbb{N} \setminus \{0\}$):

- Two subsequences $\{t_{k_i}\}_{i \in \mathbb{N}^*}$ and $\{t_{l_i}\}_{i \in \mathbb{N}^*}$ are equivalent iff
  $$[t_{k_i}]_{i \in \mathbb{N}^*} \sim [t_{l_i}]_{i \in \mathbb{N}^*}$$

- Two subsequences $\{t_{k_i}\}_{i \in \mathbb{N}^*}$ and $\{t_{l_i}\}_{i \in \mathbb{N}^*}$ are equivalent iff
  $$\sup_{i \in \mathbb{N}^*} (\|I_i\|, \|J_i\|) < \infty$$
  where
  $$I_i : [t_{l(i)} \mid k_{i-1} < l_n \leq k_i] \mapsto l_1$$
  and
  $$J_i : [t_{k(k_n)} \mid l_{i-1} < k_n \leq l_i] \mapsto l_1$$
  are the formal identities ($k_0 := l_0 := 0$).

- $\{t_i\}_{i \in \mathbb{N}^*}$ and $\{t_{k_i}\}_{i \in \mathbb{N}^*}$ are equivalent iff the function $k : \mathbb{N}^* \rightarrow \mathbb{N}^*$ is majorized by a primitive recursive function.

We can see subsets $A \subset \mathbb{N}^*$ as strictly increasing functions $a : \mathbb{N}^* \rightarrow \mathbb{N}^*$, simply let $a$ enumerate $A$ in the usual order. In the same way, strictly increasing functions can be seen as infinite subsets of $\mathbb{N}^*$. Now the relation of $b$ majorizing $a$ is in fact closed in $(2^\omega \setminus FIN)^2$ and has closed, nowhere dense sections:

$$a \leq b \equiv \forall n \ a(n) \leq b(n) \equiv$$

$$\forall n \ \forall m, k \left[ \forall m_1 < m_2 < \ldots < m_n < m \ \exists i B(m_i) = 0 \land \right.$$

$$\exists m_1 < m_2 < \ldots < m_n = m \forall i B(m_i) = 1 \land$$

$$\forall k_1 < k_2 < \ldots < k_n < k \ \exists i A(k_i) = 0 \land$$

$$\exists k_1 < k_2 < \ldots < k_n = k \ \forall i A(k_i) = 1 \rightarrow k \leq m \right]$$
So it’s closed and it is easily seen that no function $a$ can be such that it majorizes all functions belonging to some basic open set $N_a$ (on the other hand $n \mapsto n$ minorizes all functions), whence the sections (in one of the coordinates) have empty interior.

The set $\{A \subseteq N^* \mid A \cong N^*\}$ is the countable union of closed nowhere dense sets, hence meager.

Now take any $A \not\cong N^*, A = \{a_n\}_{n \in N^*}$. As it generates a sequence non equivalent with the full basis there are disjoint nonempty intervals $[r_1, s_1], [r_2, s_2], \ldots \subset \complement A$ such that for the formal identities $I_i : [t_n \mid n \in [r_i, s_i]] \hookrightarrow l_1$ we have $\|I_i\| > i$. So if $B \cong A$ then $\exists i \forall j \geq i \ [r_j, s_j] \not\subset B$, which again easily is seen to be the countable disjunction of closed, nowhere dense conditions.

Therefore every isomorphism class for the Tsirelson space is meager in $2^\omega \setminus FIN$. However, using the functions $n \mapsto 2n$ and $n \mapsto 2n + 1$, it is seen that the space is isomorphic to its square.

Though the notion of ‘complement’ of a set is not absolute, ie. it depends on the ambient space, $\cong$ is so. This is to say that $A \cong B$ does not depend on whether $A$ and $B$ are seen as subsets of $\mathbb{N}$ or of any other $C \subseteq \mathbb{N}, A, B \subseteq C$.

Denote by $2^A$ the closed set $\{\chi_B \in 2^\omega \mid B \subseteq A\}$. If $A$ is infinite then this set is homeomorphic to $2^\omega$ and we can use our preceding arguments thereon.

So if for some $A$ the restriction of $\cong$ to $2^A$ is meager in $2^A$ there are $2^\omega$ classes of isomorphism generated by subsequences of $A$, hence also of $\mathbb{N}$.

If not there is some residual in $2^A$ isomorphism class and we get as before that $[e_i]_{i \in A}$ is isomorphic to its hyperplanes, to its square, to $[e_i]_{i \in A} \oplus [e_i]_{i \in D}$ for any $D \subset A$ and to a denumerable Schauder decomposition into isomorphic copies of itself, $[e_i]_{i \in A} \cong (\sum_{k \in \mathbb{N}} \oplus ([e_i]_{i \in B_k}))$.

There is a priori no control on the uniformity of the isomorphisms between each space $[e_i]_{i \in A}$ and its square. Notice also that the existence of an isomorphism $A \oplus D \cong A$ for $D$ infinite subset of $A$ is straightforward from the assumption that $A \cong A \oplus A$ for all infinite $A \subseteq \mathbb{N}$. For then $A \oplus D \cong (A \setminus D) \oplus D \oplus D \cong (A \setminus D) \oplus D \cong A$, for all infinite $D \subset A$.

The diligent reader is invited to amuse himself in applying the above proof to the cases of Lipschitz homeomorphism, uniform homeomorphism and permutative equivalence of bases (all three are analytic equivalence relations).

**Theorem 12** Let $X$ be a Banach space with an unconditional basis $\{e_i\}_{i \in \mathbb{N}}$. Then either:
(1) There exists a perfect set \( P \subset 2^\omega \) of infinite subsets of \( \mathbb{N} \) such that for any two distinct \( A, B \in P \) we have that

\[
[e_i]_{i \in A} \not\cong [e_i]_{i \in B}
\]

or

(2) For any infinite subset \( A \subset \mathbb{N} \): \([e_i]_{i \in A}\) is isomorphic to its hyperplanes, to its square, and to a denumerable Schauder decomposition into uniformly isomorphic copies of itself, \([e_i]_{i \in A} \cong (\sum_{k \in \mathbb{N}} \oplus([e_i]_{i \in B_k}))\).

Recall that a Banach space is complementably minimal if it embeds complementably in any of its subspaces. Using Pelczynski's decomposition method and the above result, one proves:

**Corollary 13** Let \( X \) be a complementably minimal Banach space with an unconditional basis \( \{e_i, i \in \mathbb{N}\} \). Then

(1) There exists a perfect set \( P \subset 2^\omega \) of infinite subsets of \( \mathbb{N} \) such that for any two distinct \( A, B \in P \) we have that

\[
[e_i]_{i \in A} \not\cong [e_i]_{i \in B}
\]

or

(2) For any infinite subset \( A \subset \mathbb{N} \), \([e_i]_{i \in A}\) is isomorphic to \( X \).

## 5 The number of nonisomorphic subspaces of hereditarily indecomposable Banach spaces.

This result was proved by the second-named author before the authors's collaboration began.

Let now \( X \) be some separable hereditarily indecomposable (H.I.) Banach space. This means that no (closed, infinite dimensional) subspace of \( X \) can be written as a direct sum of two closed infinite dimensional subspaces. In this section 'space' will always refer to closed infinite dimensional subspaces of \( X \). It follows clearly from the H.I. property that \( X \) contains no unconditional basic sequence; and in fact, by Gowers's dichotomy theorem, every Banach space contains either a H.I. subspace or a subspace with an unconditional basis. Moreover Gowers and Maurey proved that a H.I. space is isomorphic to no proper subspace (and as the H.I. property is hereditary, this is also true of any subspace of \( X \)).

Now since we have the first property we cannot hope to use the above theorem to conclude something about the number of nonisomorphic subspaces of \( X \), but it is still
possible to use the fact that $\mathcal{X}$ must contain some basic sequence $\{e_i\}_{i \in \mathbb{N}}$. Again we look at the subspaces spanned by subsequences as points in $2^\omega$.

According to Dedekind every real is a set of rational numbers $r = \{q \in \mathbb{Q} | q < r\}$, but following Cantor the set of rational numbers is the same as the set of natural numbers. So every real $r$ is a set $A_r$ of natural numbers such that $r < s \equiv A_r \subsetneq A_s$. Now again confusing Banach spaces with subsets of $\mathbb{N}$, reals become for us a subspace $\mathcal{B}_r$ and the relation $r < s$ is simply strict inclusion $\mathcal{B}_r \subsetneq \mathcal{B}_s$. All of the identifying functions are of course (and evidently) Borel. So we have $2^\omega$ nonisomorphic subspaces of $\mathcal{X}$.

This could also have been seen using the arguments from the preceding section, for suppose that some isomorphism class $\mathcal{A}$ was residual in $2^\omega$ then as $\{0\} \Delta(\cdot)$ is a homeomorphism of $2^\omega$

$$\mathcal{A} \cap \{\{0\} \Delta A | A \in \mathcal{A}\} \neq \emptyset$$

So there is some $B \subset \mathbb{N}, 0 \notin B$ with $B, \{0\} \in \mathcal{A}$, i.e. some subspace of $\mathcal{X}$ isomorphic to a hyperplane. But this cannot be the case in an H.I. space, so $\cong$ must be meager in $2^\omega$ and the Kuratowski/Mycielski result takes care of the rest.

**Proposition 14** Any H.I. Banach space contains $2^\omega$ pairwise non isomorphic subspaces.

**Corollary 15** Any Banach space contains $2^\omega$ pairwise non isomorphic subspaces or is saturated with subspaces isomorphic to their squares.
