Nowadays, geometric tools are being used to treat a huge class of problems of quantum information science. By understanding the interplay between the geometry of the state space and information-theoretic quantities, it is possible to obtain less trivial and more robust physical constraints on quantum systems. In this sense, here we establish a geometric lower bound for the Wigner-Yanase skew information (WYSI), a well-known information theoretic quantity recently recognized as a proper quantum coherence measure. Starting from a mixed state evolving under unitary dynamics, while WYSI is a constant of motion, the lower bound indicates the rate of change of quantum statistical distinguishability between initial and final states. Our result shows that, since WYSI fits in the class of Petz metrics, this lower bound is the change rate of its respective geodesic distance on quantum state space. The geometric approach is advantageous because raises several physical interpretations of this inequality under the same theoretical umbrella.

Introduction.— Coherence is a striking feature of the quantum realm due to interference phenomena [1]. In fact, it is in equal footing with entanglement and other correlations whose meaning evades the classical view. Although quantum optics has proved to be a fruitful branch for quantum coherence studies [2], recent results suggest its connection with thermodynamics [3] and quantum biology [4]. Even some condensed matter phases, such as superconductivity and its emergent properties, display signatures of quantum coherence [5]. As we know, the inability to perform basic tasks in quantum information processing is often related to coherence loss and, because of that, the interplay between noise and decoherence still holds as a key challenge in open quantum systems. Recently, Bromley and coworkers [6] reported a possible way to circumvent this problem. Summarizing, they found a regime called freezing conditions in which coherence remains unchanged during the nonunitary dynamics.

Despite its fundamental role in physics, there is no unified way to characterize and quantify coherence. A recent approach due to Baumgratz et al. [7] established a new paradigm in this scenario. By employing a rigorous mathematical framework for identifying proper coherence measures, they were able to classify natural candidates for coherence quantifiers based on distance measures, particularly relative entropy, $l_p$-norms, and fidelity [7]. Simultaneously, Girolami [8] proposed another quantum coherence measure based on the Wigner-Yanase skew information (WYSI), which shares the same reliable criteria of Ref. [7]. Besides the theoretical background, this work offers an efficient route to experimentally access the quantum coherence of an unknown state.

For the reasons presented along the text, in this paper we focus on skew information to provide a geometric-lower bound for coherence measures. This new approach is general enough in order to provide a unified view for quantum coherence, since it lies only on the geometrical structure of the state space. Our main result, given in Eq. (15), provides a deeper understanding of this valuable quantum resource.

Introduced by Wigner and Yanase half century ago [9], skew information

$$I(\rho, \mathcal{K}) := -\frac{1}{2} \text{Tr}(\sqrt{\rho} \mathcal{K} \sqrt{\rho})$$

(1)

is a measure of the non-commutativity between a state $\rho$ and an observable $\mathcal{K}$. Operationally, this quantity is deeply more interesting than other coherence quantifiers because its calculation does not involve any optimization techniques. It also describes a constant of motion in closed quantum dynamics [10]. Furthermore, WYSI is nonnegative, convex and vanishes if and only if the state and the observable commute, i.e., if the state is a coherent one [11]. It is also bounded by the variance of $\mathcal{K}$, $I(\rho, \mathcal{K}) \leq \langle \mathcal{K}^2 \rangle_\rho - \langle \mathcal{K} \rangle_\rho^2$, an interesting property discovered by Luo which also noticed that the inequality is saturated for pure states [12]. This measure was later generalized by Dyson as

$$I^p(\rho, \mathcal{K}) := -\frac{1}{2} \text{Tr}([\rho^p \mathcal{K}][\rho^{1-p} \mathcal{K}])$$

(2)

with $0 < p < 1$, being called Wigner-Yanase-Dyson skew information (WYDSI), and its convexity proved by Lieb [13].

There are several interpretations of the skew information, each one related to a particular viewpoint of the quantum behavior. Actually, the original one discusses the uncertainty in the measure of observables not commuting with a conserved quantity —basically, the content of Wigner-Yanase-Araki theorem [14]. Similarly, WYSI supports a new type of Heisenberg uncertainty relation [15], quantifies the quantum uncertainty of local observables [16], and has applications in quantum reference frames and metrology [17]. It is also possible to detect entangled states through a Bell-type inequality derived from the skew information [18].

WYSI is also an asymmetry measure, i.e., it quantifies symmetry breaking in a given state [19]. This is a promising subject in quantum information which finds support on the asymmetry theory and classifies coherence as a resource [20]. In this context, Noether’s theorem is a powerful tool to characterize conservation laws from symmetries in closed quantum systems because each asymmetry measure is a conserved quan-

---

* diegopaivapires@gmail.com
tity. Nevertheless, recent efforts have elucidated some asymmetry properties of pure states and quantum channels [21], but the mixed state case is rather complex and less exploited. This happens because, when dealing with mixed states, we must search for conservation laws which are not captured in its essence by Noether’s theorem [22]. As advocated by Marvian and Spekkens [23], an asymmetry measure based on WYSI could fill this gap providing a way to point out more subtle features of conserved quantities.

In the following, we discuss the necessary and sufficient conditions that WYSI should be satisfy in order to be a proper coherence measure. This information-theoretic quantity defines a monotone Riemannian metric due to the Petz’s theorem [24] and its respective geodesic distance on quantum state space is given by the Hellinger angle [25]. By exploring these two interfaces, we demonstrate an inequality which assigns a geometric meaning to coherence measures. In other words, we show that skew information is lower bounded by the rate of change of distinguishability between two states for closed quantum systems. Furthermore, this bound can be viewed as a constraint over the asymmetry measure based on WYSI.

**WYSI and quantum coherence measures.**— In order to characterize skew information as a coherence measure, it is essential to establish the concept of incoherent states and incoherent operations. An incoherent state is one that has no coherence, i.e., its off-diagonal elements are equal to zero. In the same way, an incoherent operation is one that does not create any kind of coherence. Despite the intuitive notions, in the following we will present these ideas in a rigorous fashion.

It is well known that quantum operations are described by dynamical maps also known as quantum channels. In particular, the action of completely positive and trace preserving (CPTP) map $E$ on the state $\rho$ can be synthetized as $E(\rho) = \sum\rho_i K_i \rho K_i^\dagger$, where $\{K_i\}$ is a set of Kraus operators satisfying $\sum K_i^\dagger K_i = 1$. Let $H$ be a finite-dimensional Hilbert space with $d = \text{dim} H$. Choosing a fixed basis $\{|i\rangle\}_{i=1,...,d}$, the subset of incoherent states $I \subset H$ encompasses those whose density matrix is diagonal in this basis. So, an incoherent channel (ICPTP) is the map $K_i : I \rightarrow I$ for all $\mu$, i.e., transform incoherent states into incoherent states. In other words, this constraint excludes any coherence generation process.

As demonstrated by Girolami [8], skew information is a faithful coherence measure since it satisfies the axiomatic postulates proposed by Baumgratz et al [7]. First, it is convex, non-negative and vanishes for all incoherent states $\rho \notin I$. Indeed, $I(\rho, K) = 0$ if and only if $[\rho, K] = 0$, i.e., state and observable can be diagonalized simultaneously. Secondly, it is monotonically nonincreasing under ICPTP maps and does not increase on average under a von Neumann measurement, $I(\rho, K) \geq \sum_p p_I(K_i \rho K_i^\dagger, K)$, where $p_i = Tr(K_i \rho K_i^\dagger)$.

**WYSI, Petz metric and Hellinger angle.**— WYSI is a robust information-theoretic quantifier due its enormous versatility. Actually, skew information also can be interpreted from a geometric perspective. The most remarkable approach to achieve this goal is indubitably due to Morozova-Cencov [26] and Petz [24, 27], by using monotone metrics on the quantum state space. In this space the set of density operators $\{\rho \geq 0 \text{ and } Tr \rho = 1\}$ constitute a differentiable manifold equipped with a suitable monotone Riemannian metric. By monotone metrics we consider the ones that are defined by positive, continuous and sesquilinear inner products which are also contractive under CPTP maps.

The Morozova-Cencov-Petz theorem provides a friendly way to demonstrate that skew information fits in the category of monotone metrics and describes a particular kind of quantum Fisher information [28]. Generally speaking, the theorem states that there exists a bijective correspondence between monotone metrics and operator monotone functions given by

$$g_f(A, B) := \text{Tr}[A c_f(\mathcal{L}, \mathcal{R}) B],$$

where

$$c_f(x, y) := \frac{1}{y f(x/y)}$$

is a symmetric function, $c_f(x, y) = c_f(y, x)$, and fulfills $c(ax, ay) = c(x, y)$, $0 \leq c(x, y) \leq 1$, $c(x, x) = 1$, and $c(x, y) = 0$ if $x, y > 0$. Here $\mathcal{L} = \mathcal{L}^\dagger = \mathcal{R} = \mathcal{R}^\dagger$ is the map whose density matrix is diagonal in this basis. So, an incoher-

eral observable can be diagonalized simultaneously. Secondly, it is convex, non-negative and vanishes for all incoherent states $\rho \notin I$. Indeed, $I(\rho, K) = 0$ if and only if $[\rho, K] = 0$, i.e., state and observable can be diagonalized simultaneously. Secondly, it is monotonically nonincreasing under ICPTP maps and does not increase on average under a von Neumann measurement, $I(\rho, K) \geq \sum p_i I(K_i \rho K_i^\dagger, K)$, where $p_i = Tr(K_i \rho K_i^\dagger)$.
Since the quantum state space is endowed with a metric structure, it is natural to ask about distances, curvature and other geometric properties. Particularly, the notion of distance between states has been the subject of discussions initiated decades ago under the spotlight of statistical inference [32]. In a pioneering work, Wootters employed the statistical distance concept as a proper distinguishability measure between statistical probabilities [33]. The geometrization of this problem emerged years later with Braunstein and Caves [34] who defined a Riemannian metric and its respective line element $ds$ from a suitable distinguishability quantifier between close states. Though their description was based on a physical ground, it is analogous to that one developed by Petz which relies on monotone metrics. Summarizing, the main message about those works lies on the close relation between state discrimination and geometric distances.

Following Petz approach for the WYSI monotone metric, it has been proved that the distance between two density matrices on quantum state space is $D(\rho, \sigma) = 2 - 2\text{Tr}(\sqrt{\sqrt{\rho} \sqrt{\sigma}})$ [25]. The last quantity is the quantum analogue of the classical Hellinger distance [32]. Our discussion on the geometric properties of WYSI should include a few lines about geodesics — the shortest distance between two density matrices on the quantum state space — associated to the Wigner-Yanase monotone metric. It was shown that the corresponding geodesic joining the density operators $\rho$ and $\sigma$ is given by the Hellinger angle [25, 35]

$$L(\rho, \sigma) = \arccos[\text{Tr}(\sqrt{\rho} \sqrt{\sigma})].$$

The quantity $A(\rho, \sigma) = \text{Tr}(\sqrt{\rho} \sqrt{\sigma})$ is called quantum affinity and describes how close two states are on the quantum state space [32]. Moreover, it is remarkable that quantum affinity is bounded from below by the Quantum Chernoff Bound (QCB) [36].

**Geometric lower bound on quantum coherence.**— We now provide a lower bound for the quantum coherence measure based on the skew information. Let us focus on a driven closed quantum system described initially by a mixed state $\rho_0$ which undergoes a unitary transformation $\rho_\varphi = U_\varphi \rho_0 U_\varphi^\dagger$. Essentially, this operation encodes the parameter $\varphi$ on the input state and does not change its purity. The reason for starting from a mixed state is twofold: first, the skew information is bounded by the variance when dealing with mixed states [10, 11]. Actually, this result was improved later by a variance lower bound which is tighter than this one based on the skew information [31]. Moreover, it also allowed to derive an entire family of higher-order corrections to the uncertainty relation supported by WYSI by exploiting its connection with the quantum analogue of the conditional variance; second, because all Petz’s metrics — particularly the Wigner-Yanase one — becomes the well known Fubini-Study metric for pure states [37].

Considering the Wigner-Yanase metric in the quantum state space, according to Eq. (7) we obtain

$$\left| \frac{d}{d\varphi} \cos[L(\rho_0, \rho_\varphi)] \right| = \left| \frac{d}{d\varphi} \text{Tr}(\sqrt{\rho_0} \sqrt{\rho_\varphi}) \right|. \tag{8}$$

Since $U_\varphi$ is a unitary operator, it is possible to write $\sqrt{\rho_\varphi} = U_\varphi \sqrt{\rho_0} U_\varphi^\dagger$ which implicates the von Neumann equation [38]

$$\frac{d}{d\varphi} \sqrt{\rho_\varphi} = -\frac{i}{\hbar} [K_\varphi, \sqrt{\rho_\varphi}], \tag{9}$$

where we used that $(dU_\varphi/d\varphi) U_\varphi^\dagger = -U_\varphi (dU_\varphi^\dagger/d\varphi)$ and defined the Hermitian operator

$$K_\varphi = -i\hbar U_\varphi \frac{dU_\varphi^\dagger}{d\varphi}. \tag{10}$$

For a unitary dynamics $U_\varphi = e^{-iH\varphi}$ (thus $K_\varphi = H$, with $H$ an arbitrary observable independent of the parameter $\varphi$). Substituting Eq. (9) into Eq. (8), we have

$$\left| \frac{d}{d\varphi} \cos[L(\rho_0, \rho_\varphi)] \right| \leq \frac{1}{\hbar} \| [K_\varphi, \sqrt{\rho_\varphi}] \|_2. \tag{11}$$

Equation (11) is the starting point for establishing the lower bound on the skew information. Actually, this goal is reached by noting that

$$\| [K_\varphi, \sqrt{\rho_\varphi}] \|_2 \leq \| I(\rho_\varphi, K_\varphi) \|_2 \equiv \| \rho_\varphi \|_2$$

where we used the Cauchy-Schwarz inequality $|\text{Tr}(AB)| \leq \|A\|_2 \|B\|_2$, with $\|A\|_2 = \sqrt{\text{Tr}(A^A)}$ being the Schatten $\|\cdot\|_2$ (also known as Hilbert Schmidt or Fröbenius norm) [39]. Combining Eq. (12) and $\| \rho_0 \|_2 = 1$, and substituting the result into Eq. (11), we obtain

$$\left| \frac{d}{d\varphi} \cos[L(\rho_0, \rho_\varphi)] \right| \leq \frac{1}{\hbar} \| [K_\varphi, \sqrt{\rho_\varphi}] \|_2. \tag{13}$$

On the other hand, noting that

$$\| [K_\varphi, \sqrt{\rho_\varphi}] \|_2 = \sqrt{-\text{Tr}( [K_\varphi, \sqrt{\rho_\varphi}]^2 )} = \sqrt{2I(\rho_\varphi, K_\varphi)} \tag{14}$$

where $I(\rho_\varphi, K_\varphi) = -(1/2)\text{Tr}( [\sqrt{\rho_\varphi}, K_\varphi]^2 )$ is the Wigner-Yanase skew information (WYSI). Therefore, substituting Eq. (14) into Eq. (13) we obtain a lower bound in terms of Wigner-Yanase skew information and Hellinger angle as follows

$$\left| \frac{d}{d\varphi} \cos[L(\rho_0, \rho_\varphi)] \right| \leq \frac{\sqrt{2}}{\hbar} \sqrt{I(\rho_\varphi, K_\varphi)}. \tag{15}$$

Recalling that unitary evolution does not change the purity of a quantum state, if $\rho_0$ is pure, then $\rho_\varphi$ will also be, and the skew information (asymmetry measure) reduces to the variance of $K_\varphi$, i.e., $I(\rho_\varphi, K_\varphi) = (\Delta K_\varphi)^2 = \langle K_\varphi^2 \rangle - \langle K_\varphi \rangle^2$. In this case, the lower bound becomes

$$\Delta K_\varphi \geq \frac{\hbar}{\sqrt{2}} \left| \frac{d}{d\varphi} f(\varphi) \right|, \tag{16}$$

where $f(\varphi) = \text{Tr}[\rho_0 \rho_\varphi^\dagger]/\text{Tr}\rho_0^2$ defines the relative purity, which played a special role for the investigation of quantum speed limits under the closed dynamics [40].
Example.—To illustrate the use of the bound indicated in Eq. (15), we now consider the single qubit case. Let $\rho_0 = (1/2)(I + \hat{r}_0 \cdot \hat{\sigma})$ be the initial state ($I$ denotes the $2 \times 2$ identity matrix, $\hat{r}_0$ is a 3-dimensional vector with $|\hat{r}_0|^2 = r_0^2 < 1$ and $\hat{\sigma} = (\sigma_1, \sigma_2, \sigma_3)$ is the vector of the Pauli matrices). The dynamics is governed by the self-commuting local observable $K_\varphi = \sigma(\alpha I + \hat{r}_\varphi \cdot \hat{\sigma})$, i.e., $[K_\varphi, K_{\varphi'}] = 0$ for all $\varphi$ and $\varphi'$, where $\sigma$ and $\alpha$ are positive constants and $\hat{r}_\varphi$ is an unit vector, $|\hat{r}_\varphi| = 1$. The system evolves under a general unitary operator $U_\varphi$ given by

$$U_\varphi = \exp \left[ -i \hbar \int_0^\varphi d\varphi' K_{\varphi'} \right] = e^{-i\delta \gamma} [\cos \gamma - i \hat{\Sigma}_\varphi \cdot \hat{\sigma}] \sin \gamma,$$

(17)

where $\gamma = \varphi \hat{\Sigma}_\varphi / \hbar$ and $\delta = \varphi \hat{\Sigma}_\varphi / \hbar$ are dimensionless constants and also

$$\hat{\Sigma}_\varphi := \frac{1}{\varphi} \int_0^\varphi d\varphi' \hat{r}_\varphi.$$

(18)

Essentially, the initial state $\rho_0$ undergoes the unitary transformation $\rho_\varphi = U_\varphi \rho_0 U_\varphi^\dagger$ which encodes the parameter $\varphi$. It is possible to verify that the final state can be written as

$$\rho_\varphi = (1/2)(I + \hat{r}_\varphi \cdot \hat{\sigma})$$

where $\hat{r}_\varphi = \cos(2\varphi)\hat{r}_0 + [1 - \cos(2\varphi)](\hat{\Sigma}_\varphi \cdot \hat{r}_0)\hat{\Sigma}_\varphi + \sin(2\varphi)(\hat{\Sigma}_\varphi \times \hat{r}_0).$

(19)

In this state the Bloch sphere vector $\hat{r}_\varphi$ keeps the entire information about the parameter $\varphi$ and has the same magnitude as the initial vector $\hat{r}_0$, i.e., $|\hat{r}_\varphi| = |\hat{r}_0| = r_0$. Particularly, if $\hat{r}_\varphi$ is independent of the parameter $\varphi$, i.e., $\hat{r}_\varphi = \hat{h}$, then Eq. (18) implies that $\hat{\Sigma}_\varphi = \hat{h}$ and, consequently, $\gamma = \varphi \hat{h} / \hbar$.

In order to calculate the Helminger angle we need to determine the trace of the product of operators $\sqrt{\rho_0}$ and $\sqrt{\rho_\varphi}$. The analytical expressions for the square root of a single qubit state can be found in [38]. Since the modulus of Bloch sphere radius remains constant under the unitary transformation, it is possible to verify that the Helminger angle becomes

$$\cos[\mathcal{L}(\rho_0, \rho_\varphi)] = \frac{1}{2} \left[ \xi_+ + \xi_-(\hat{r}_\varphi \cdot \hat{r}_0) \right],$$

(20)

where $\xi_{\pm} = 1 \pm \sqrt{1 - r_0^2}$ is independent of the parameter $\varphi$. From this result is straightforward to check that

$$d \cos[\mathcal{L}(\rho_0, \rho_\varphi)] / d\varphi = \left( \xi_- / 2 \right) (dp_\varphi / d\varphi) \cdot \hat{r}_0.$$ Similarily, the Wigner-Yanase skew information is given by

$$I(\rho_\varphi, K_\varphi) = \varphi^2 \xi_- |\hat{r}_\varphi \times \hat{h}|^2.$$ (21)

Substituting the derivative of Eq. (20) on the parameter $\varphi$ and Eq. (21) into Eq. (15), we finally obtain the bound $\sqrt{\xi_-} (dp_\varphi / d\varphi) \cdot \hat{r}_0 \leq 2 \sqrt{2} (\varphi / h) \hat{\Sigma}_\varphi \times \hat{h}$. To clarify, choosing the probe state $\rho_0 = (1 - r_0)I + r_0|\psi\rangle\langle\psi| = (1/\sqrt{2})(|0\rangle + |1\rangle)$, and $\hat{h} = (0, 0, 1)$, which corresponds to take $\hat{r}_0 = r_0(\cos \phi, \sin \phi, 0)$ ($0 < r_0 < 1$ and $0 \leq \phi \leq 2\pi$) and $K_\varphi = \varphi (\alpha I + \sigma_z)$, the Helminger angle is $\cos[\mathcal{L}(\rho_0, \rho_\varphi)] = (1/2)[\xi_+ + \xi_- \cos(2\varphi)]$ and the WYSI gives $I(\rho_\varphi, K_\varphi) = \varphi^2 \xi_- \sin^2 \phi$.

Combining both results we obtain the bound $\sqrt{\xi_-} |\sin(2\varphi)| \leq \sqrt{2} (\varphi / h) \sin \phi$. It is interesting to note that, while $\mathcal{L}(\rho_0, \rho_\varphi)$ is a function of the parameter $\varphi$, WYSI is independent of this phase and describes a constant of motion during the unitary evolution. It is worth mentioning that although we focused attention in the single qubit case, our calculations can be extended to a system of $N$ qubits.

Conclusions.— In this article we established a geometric lower bound for a proper quantum coherence measure based on Wigner-Yanase skew information. This information-theoretic quantity is regarded as a particular extension of Fisher information and can be seen as a monotone Riemannian metric due to the Petz’s theorem [24]. Moreover, its related geodesic distance on quantum space state is given by the Helminger angle [25]. In opposition to many other distance measures such as Bures angle or even relative entropy, Helminger angle is advantageous quantity because it technically easier to calculate and more intuitive to obtain from its classical statistical analogous. Despite those motivational issues, it has received little attention beyond that devoted to the exploration of its useful algebraic properties to the information theory. It is important to emphasize that our result shows that, since geodesic distance quantifies the discrimination of two density operators in the context of quantum statistical estimation theory [32], skew information is bounded from below by the rate of change of distinguishability between two states on quantum state space.

Our result opens a wide range of possible physical interpretations. First, inequality Eq. (15) suggests a route for better understanding the phase estimation paradigm in quantum metrology [41]. In fact, it can provide a precision bound for an unknown parameter $\varphi$ encoded by the unitary transformation in the initial state. Therefore, because WYSI remains as a conserved quantity in the closed quantum system, the bound essentially depends on the derivative of the Helminger angle with respect to this parameter.

In particular, choosing $\varphi = \tau$, where $\tau$ is time, it can be shown that our inequality gives rise to a new quantum speed limit [42]. In contrast with the original one proposed by Mandelstamm-Tamm [43], and later generalizations for driven closed systems [44], this speed limit depends on WYSI and the Helminger angle rather than the Bures angle or the variance of the hamiltonian.

Besides, it seems possible to attribute a thermodynamic meaning for this bound by investigating the connection between nonequilibrium entropy production [45] and the thermodynamic length [46] involving quantum protocols at finite temperature. This could provide a thermodynamic interpretation for the existence of the quantum speed limit.

Finally, in a future work it will be crucial to investigate the eventual relation between geometric bounds and the universality class of Petz metrics which fulfills the requirements for a quantum coherence measure. Moreover, to enlarge the present analysis, take into account the open quantum dynamics would be essential not only for the foundations of quantum information theory but also for realizing quantum technology in a noisy scenario. From the experimental point of view, by extending our conclusions to $N$ qubit systems, the bound in Eq.
could be experimentally investigated through a measurement scheme based on two-point correlation functions [47].

I. MATRIX POWERS

In this section we will demonstrate that the identity $(UAU^\dagger)^s = UAU^s$ still holds for $0 < s < 1$, where $\Lambda$ is a positive matrix ($\Lambda > 0$) and $U$ is an unitary operator, $U^\dagger = U^{-1}$. In order to reach the main goal, let us consider a monotone function $f(a) = a^s$ for $a > 0$. It can be demonstrated that $f(a)$ has the following integral representation [S1]

$$a^s = \frac{\sin(\pi s)}{\pi s} \int_0^\infty \frac{a \mu(x)}{a + x} \, dx,$$  \hspace{1cm} (S1)

where $\mu(x) = x^s$, $\mu(x) = xx^{-1} \, dx$, is a positive measure on $(0, \infty)$. This relation can be extended to the positive and non-singular operator $\Lambda$ as follows [S2]

$$\Lambda^s = \frac{\sin(\pi s)}{\pi s} \int_0^\infty \Lambda(\Lambda + xI)^{-1} \, dx.$$ \hspace{1cm} (S2)

Actually, the last condition can be relaxed if $\Lambda$ is full rank or if we assume that the inverse operation is taken on its support, i.e., the vector subspace spanned by the eigenvectors with non-zero eigenvalues [S3]. Considering the transformation $UAU^\dagger$, follows

$$(UAU^\dagger)^s = \frac{\sin(\pi s)}{\pi s} \int_0^\infty UAU^\dagger(UAU^\dagger + xI)^{-1} \, dx,$$

$$= U \frac{\sin(\pi s)}{\pi s} \int_0^\infty \Lambda(\Lambda + xI)^{-1} \, dx U^\dagger$$

$$= U \Lambda^s U^\dagger.$$  \hspace{1cm} (S4)

Therefore, we can prove our main goal combining the previous equality with the integral representation indicated in Eq. (S2), i.e.,

$$(UAU^\dagger)^s = \frac{\sin(\pi s)}{\pi s} \int_0^\infty UAU^\dagger(UAU^\dagger + xI)^{-1} \, dx,$$

$$= \frac{U}{U} \frac{\sin(\pi s)}{\pi s} \int_0^\infty \Lambda(\Lambda + xI)^{-1} \, dx U^\dagger$$

$$= U \Lambda^s U^\dagger.$$  \hspace{1cm} (S5)

II. UNITARY EVOLUTION: A GENERAL CASE

In this section we describe the calculation of the evolved state $\rho_\varphi$ in the single qubit context. Let us assume that the quantum system dynamics is governed by the local observable $K_\varphi = \sigma(\alpha I + \hat{\alpha} \cdot \vec{\sigma})$, where $\sigma$ and $\alpha$ are positive constants and $\hat{\alpha}$ is an unit vector, i.e., $|\hat{\alpha}| = 1$. By hypothesis, this observable is self-commuting, i.e., $[K_\varphi, K_\varphi'] = 0$ for all $\varphi$ and $\varphi'$. The system evolves under a general unitary operator $U_\varphi$ given by

$$U_\varphi = \exp \left[ \frac{i}{\hbar} \int_0^\infty d\varphi' K_{\varphi'} \right]$$

$$= e^{-i\delta\alpha} \exp \left[ -i\gamma(\hat{\varphi} \cdot \vec{\sigma}) \right]$$

$$= e^{-i\delta\alpha}[I \cos \gamma - i(\hat{\varphi} \cdot \vec{\sigma}) \sin \gamma],$$ \hspace{1cm} (S6)

where $\gamma = \sigma_3 \varphi_3 / \hbar$ and $\delta = \sigma_3 \varphi / \hbar$ are dimensionless constants and also

$$\hat{\varphi}_\varphi := \frac{1}{\varphi_\varphi} \int_0^\infty d\varphi' \varphi_\varphi'.$$  \hspace{1cm} (S7)

In particular, if $\hat{\alpha}$ is independent of the phase $\varphi$, i.e., $\hat{\alpha} = \hat{\alpha}$, then $\hat{\varphi} = \hat{\alpha}$. Returning to the general case, let be an initial single qubit mixed state $\rho_0 = (1/2)(I + \hat{r}_0 \cdot \vec{\sigma})$, where $I$ denotes the $2 \times 2$ identity matrix, $|\hat{r}_0|^2 = r_0^2 < 1$ and $\vec{\sigma} = \{\sigma_1, \sigma_2, \sigma_3\}$ is a vector of the Pauli matrices. The probe state $\rho_0$ undergoes the unitary transformation $\rho_\varphi = U_\varphi \rho_0 U_\varphi^\dagger$ and can be write as

$$\rho_\varphi = \frac{1}{2}[I + (\hat{r}_0 \cdot \vec{\sigma}) \cos^2 \gamma + i(\hat{r}_0 \cdot \vec{\sigma}, \hat{\varphi}_\varphi \cdot \vec{\sigma}) \sin \gamma \cos \gamma + (\hat{\varphi}_\varphi \cdot \vec{\sigma}) (\hat{r}_0 \cdot \vec{\sigma})(\hat{\varphi}_\varphi \cdot \vec{\sigma}) \sin^2 \gamma].$$ \hspace{1cm} (S8)

Exploring the algebraic properties of Pauli matrices is possible to check that $(\vec{a} \cdot \vec{\sigma})(\vec{b} \cdot \vec{\sigma}) = (\vec{a} \cdot \vec{b}) I + i(\vec{a} \times \vec{b}) \cdot \vec{\sigma}$. Combining this relation with the vector identities $\vec{a} \cdot (\vec{a} \times \vec{b}) = 0$ and $\vec{a} \times (\vec{b} \times \vec{c}) = (\vec{a} \cdot \vec{c}) \vec{b} - (\vec{a} \cdot \vec{b}) \vec{c}$, we obtain

$$[\hat{r}_0 \cdot \vec{\sigma}, \hat{\varphi}_\varphi \cdot \vec{\sigma}] = -2i(\hat{\varphi}_\varphi \times \hat{r}_0) \cdot \vec{\sigma}.$$ \hspace{1cm} (S9)

Substituting Eq. (S8) into Eq. (S7) and performing the calculations, it is possible to verify that the evolved operator $\rho_\varphi$ becomes $\rho_\varphi = (1/2)(I + \hat{\alpha} \cdot \vec{\sigma})$, with

$$\hat{\alpha}_\varphi = \cos(2\gamma) \hat{r}_0 [1 - \cos(2\gamma)](\hat{\varphi}_\varphi \cdot \hat{r}_0) \hat{\varphi}_\varphi + \sin(2\gamma)(\hat{\varphi}_\varphi \times \hat{r}_0).$$ \hspace{1cm} (S10)

It is worth to emphasize that both vectors $\hat{\alpha}_\varphi$ and $\hat{r}_0$ has the same absolute value, $|\hat{\alpha}_\varphi|^2 = |\hat{r}_0|^2 = r_0^2$. In other words, the unitary transformation $U_\varphi$ does not change the modulus of Bloch sphere radius during the dynamics.

Now we will provide another proof for Eq. (S10) which is based on the so-called Rodrigues’ rotation formula. Summarizing, through this approach the vector $\hat{\alpha}_\varphi$ is completely determined by the action of a rotation matrix on the initial vector $\hat{r}_0$. In order to understand this property, let be the $j$–$\hat{r}_0$ component $(\hat{\alpha}_\varphi)_j = (\hat{\varphi}_\varphi)_j(\hat{r}_0)_j$, with

$$(\hat{\varphi}_\varphi)_j = \cos(2\gamma) \delta_j + [1 - \cos(2\gamma)](\hat{\varphi}_\varphi)_j(\hat{\varphi}_\varphi)_j + \sin(2\gamma)(\hat{\varphi}_\varphi)_j \hat{r}_0_j$$

and $(\hat{\varphi}_\varphi)_{\hat{r}_0} := 2(\hat{\varphi}_\varphi)_j(\hat{\varphi}_\varphi)_j$. The matrix element $(\hat{\varphi}_\varphi)_{j\hat{r}_0}$ satisfy the identity

$$(\hat{\varphi}_\varphi)_{j\hat{r}_0} = \epsilon_{j\hat{r}_0}(\hat{\varphi}_\varphi)_j(\hat{\varphi}_\varphi)_{\hat{r}_0}$$

$$= (\delta_j(\hat{\varphi}_\varphi)_j - \delta_j(\hat{\varphi}_\varphi)_j)(\hat{\varphi}_\varphi)_j$$

$$= (\hat{\varphi}_\varphi)_j(\hat{\varphi}_\varphi)_j - \delta_j.$$ \hspace{1cm} (S11)
where we used the Einstein convention for sums and the property \((\Sigma_j^\mu)(\Sigma_j^\nu)_k = [\Sigma_j^\mu]_k^2 = 1\). From this expression we have
\[ (\Sigma_j^\mu)(\Sigma_j^\nu)_k = \delta_{jk} + \Lambda_{jk}(\varphi) \Lambda_{kj}(\varphi) \] and so
\[ (S_j^\mu)_{kl} = \delta_{jk} + (1 - \cos(2\gamma))(\Lambda_{jk}(\varphi))_{kl} + \sin(2\gamma)(\Lambda_{jk}(\varphi))_{kl} \] (S13)
The matrix \(\Lambda_{jk}(\varphi)\) is called skew tri-identempotent because fulfills \(\Lambda^2_{jk} = -\Lambda_{jk}\). This property can be verified starting from the triple product
\[ (\Lambda_{jk}(\varphi))_{kl} = \epsilon_{ml}(\hat{\Sigma}_j^\mu)(\hat{\Sigma}_j^\nu)(\hat{\Sigma}_k^\rho) - \delta_{jk} \epsilon_{ml}(\hat{\Sigma}_j^\mu)(\hat{\Sigma}_k^\rho) = -((\hat{\Sigma}_j^\mu)(\hat{\Sigma}_j^\nu)(\hat{\Sigma}_k^\rho))_{kl} = -((\hat{\Sigma}_k^\rho)(\hat{\Sigma}_j^\nu)(\hat{\Sigma}_j^\mu))_{kl} \] (S14)
Note that to obtain the last equality in this expression we used the identity \(\text{I} \cdot (\hat{\Sigma}_j^\mu)(\hat{\Sigma}_j^\nu)(\hat{\Sigma}_k^\rho) = 0\). From this result the matrix \(S_j^\mu\) can be written as
\[ S_j^\mu = I + (1 - \cos(2\gamma))\Lambda^2_{jk} + \sin(2\gamma)\Lambda_{jk} \] (S15)
From this relation is possible to identify the explicit form of matrix \(\Lambda_{jk}(\varphi)\). First, this matrix has all diagonal elements equal to zero, i.e., \((\Lambda_{jk}(\varphi))_{jj} = \epsilon_{jk}(\hat{\Sigma}_j^\mu)(\hat{\Sigma}_k^\rho) = 0\). Second, the matrix \(\Lambda_{jk}(\varphi)\) is anti-symmetric because \((\Lambda_{jk})_{ij} = \epsilon_{jk}(\hat{\Sigma}_j^\mu)(\hat{\Sigma}_k^\rho) = -\epsilon_{ji}(\hat{\Sigma}_j^\mu)(\hat{\Sigma}_k^\rho) = -((\Lambda_{jk}(\varphi))_{ji})\). On the other hand, given that \((\Lambda_{jk}(\varphi))_{jj} = \epsilon_{jk}(\hat{\Sigma}_j^\mu)(\hat{\Sigma}_k^\rho) = -((\Lambda_{jk}(\varphi))_{ij})\), \((\Lambda_{jk}(\varphi))_{12} = \epsilon_{12}(\hat{\Sigma}_1^\mu)(\hat{\Sigma}_2^\rho) = -((\Lambda_{jk}(\varphi))_{21})\), \((\Lambda_{jk}(\varphi))_{13} = \epsilon_{13}(\hat{\Sigma}_1^\mu)(\hat{\Sigma}_3^\rho) = -((\Lambda_{jk}(\varphi))_{31})\), \((\Lambda_{jk}(\varphi))_{23} = \epsilon_{23}(\hat{\Sigma}_2^\mu)(\hat{\Sigma}_3^\rho) = -((\Lambda_{jk}(\varphi))_{32})\), is immediate to write \(\Lambda_{jk}(\varphi)\) as
\[ \Lambda_{jk}(\varphi) = -\hat{\Sigma}_j^\mu \cdot \hat{J} \] (S16)
where \(\hat{J} = \{J_1, J_2, J_3\}\) is a vector whose components are the generators matrices of the adjoint representation (3-dimensional) of \(\text{SU}(2)\) algebra
\[ J_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{bmatrix}, \quad J_2 = \begin{bmatrix} 0 & i & 0 \\ 0 & 0 & 0 \\ -i & 0 & 0 \end{bmatrix}, \quad J_3 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \] (S17)
Finally, substituting Eq. (S16) into Eq. (S15), the vector \(\vec{r}(\varphi)\) is written as follows
\[ \vec{r}(\varphi) = e^{-2\gamma\hat{\Sigma}_j^\mu \cdot \hat{J} r_0} \] (S18)

### III. INVERSE MATRIX, DETERMINANT AND SQUARE ROOT

In this section we provide an explicit calculation of the Hellinger angle and Wigner-Yanase skew information for a mixed single qubit state. To achieve these results we will obtain analytical expressions of the inverse matrix, determinant and square root for that state. Consider a hermitian contractive operator \(I\), i.e., \(|\|I\|\| \leq 1\), where \(|\ldots|\|\) defines the operator (or bound) norm. In this case, the positive operator \(I + II\) is invertible and its inverse
\[ (I + II)^{-1} = I - II^2 - II^3 - \ldots \]
\[ = (I - II)(I + II^2 + II^3 + \ldots) \]
\[ = (I - II)(I - II^2)^{-1} \] (S19)
defines a convergent Neumann series [S1]. Let us consider now a single qubit mixed state \(\rho_{\mu} = (1/2)(I + \vec{r}_\mu \cdot \hat{\sigma})\) with \(\mu \in [0, \varphi]\) and choose \(II = \vec{r}_\mu \cdot \hat{\sigma}\). Here \(I\) denotes the 2 × 2 identity matrix, \(\hat{\sigma} = (\sigma_1, \sigma_2, \sigma_3)\) and \(\vec{r}_\mu\) is a 3-dimensional vector which fulfills \(|\vec{r}_\mu|^2 < 1\). By using the vector identity \((\vec{a} \cdot \hat{\sigma})(\vec{b} \cdot \hat{\sigma}) = (\vec{a} \cdot \vec{b})I + i(\vec{a} \times \vec{b}) \cdot \hat{\sigma}\), is straightforward to verify \(II^2 = (\vec{r}_\mu \cdot \hat{\sigma})^2 = (\vec{r}_\mu)^2 I\) and Tr(\(II\)) = 0. Given that \(|\|I\|\| = \|\|II\|\|\), where \(\|I\| = \|\|II\|\| = \|\vec{r}_\mu\|\|\), in our case follows \(|\|I\|\| = \|\|II\|\| \leq 1\) and according to Eq. (S19) we obtain
\[ \rho_{\mu}^{-1} = 2(I + \vec{r}_\mu \cdot \hat{\sigma})^{-1} = \frac{2}{1 - |\vec{r}_\mu|^2}(I - \vec{r}_\mu \cdot \hat{\sigma}) \] (S20)
Note that the previous result is singular if the state is a pure one. Actually, in this case the inverse operation requires another approach known as generalized inverse or Moore-Penrose inverse [S4]. It is a simple task to recognize \(1 - |\vec{r}_\mu|^2\) as the determinant of the mixed state \(\rho_{\mu}\), starting from the identity
\[ \det(I + II) = e^{\text{Tr}[\ln(I + II)]} \] (S21)
In fact, since \(|\|I\|\| \leq 1\) and taking the Taylor series expansion
\[ \ln(1 + x) = -\sum_{k=1}^{\infty} (-x)^k / k \]
for \(|x| < 1\), follows
\[ \text{Tr}[\ln(I + II)] = -\sum_{k=1}^{\infty} (\frac{(-1)^k}{k}) \text{Tr}(II^k) \]
\[ = -\sum_{k=1}^{\infty} \frac{|\vec{r}_\mu|^2}{k} II^{2k} = \ln(1 - |\vec{r}_\mu|^2) \] (S22)
where we used \(\text{Tr}(II^{2k+1}) = 0\) and \(\text{Tr}(II^{2k}) = 2|\vec{r}_\mu|^2\) and collect even and odd contributions in each infinite sum. In this sense we get
\[ \det(I + \vec{r}_\mu \cdot \hat{\sigma}) = 1 - |\vec{r}_\mu|^2 \] (S23)
In order to calculate the square root of the density operator \(\rho_{\mu}\), it is convenient to remember the integral representation presented in Eq. (S2) for \(s = 1/2\), i.e.,
\[ \sqrt{\rho_{\mu}} = \frac{1}{\pi} \int_{0}^{\infty} dx \text{Tr}[\rho_{\mu}(\vec{r}_\mu + xI)^{-1}] \] (S24)
According to Eq. (S20) it can be verified that
\[ (\rho_{\mu} + xI)^{-1} = \frac{2}{1 + 2x}(I + \vec{r}_\mu \cdot \hat{\sigma})^{-1} \]
\[ = \frac{2(I - \vec{r}_\mu \cdot \hat{\sigma})}{(1 + 2x)(1 - |\vec{r}_\mu|^2)} \]
\[ = \frac{2((1 + 2x)I - \vec{r}_\mu \cdot \hat{\sigma})}{(1 + 2x)^2 - |\vec{r}_\mu|^2} \] (S25)
with \(\vec{r}_\mu = (1 + 2x)\vec{r}_\mu\), and thus
\[ \rho_{\mu}(\rho_{\mu} + xI)^{-1} = \frac{1 + 2x - |\vec{r}_\mu|^2}{(1 + 2x)^2 - |\vec{r}_\mu|^2} I + \frac{2x}{(1 + 2x)^2 - |\vec{r}_\mu|^2}(\vec{r}_\mu \cdot \hat{\sigma}) \] (S26)
Substituting the previous result into Eq. (S24) and performing the calculation of both integrals, we finally obtain

$$\sqrt{\rho_\mu} = \frac{1}{2\sqrt{2}} \left[c_\mu I + c_{\mu}^-(\hat{r}_\mu \cdot \hat{\sigma})\right], \quad \text{(S27)}$$

where

$$c_\mu^\pm := \sqrt{1 + |r_\mu|^2} \pm \sqrt{1 - |r_\mu|^2}. \quad \text{(S28)}$$

As pointed out in the main text, the Hellinger angle is determined by the equation

$$\cos(\mathcal{L}(\rho_0, \rho_\phi)) = \text{Tr}(\sqrt{\rho_0} \sqrt{\rho_\phi}) = \frac{1}{4} \left[c_0^+ c_\phi^+ + c_0^- c_\phi^- (\hat{r}_\phi \cdot \hat{\sigma})\right]. \quad \text{(S29)}$$

Analogously, the Wigner-Yanase skew information

$$I(\rho_\phi, K_\phi) = -(1/2)\text{Tr}(\sqrt{\rho_\phi} K_\phi)$$

also depends on the square root of the density operator. Considering the local observable $K_\phi = \omega(I + \hat{h}_\phi \cdot \hat{\sigma})$ it is possible to prove that

$$[\sqrt{\rho_\phi}, K_\phi] = i\frac{\omega c_\phi^-}{\sqrt{2}} (\hat{r}_\phi \times \hat{h}_\phi) \cdot \hat{\sigma} \quad \text{(S30)}$$

and also

$$[\sqrt{\rho_\phi}, K_\phi]^2 = -\frac{1}{2} (\omega c_\phi^-)^2 [\hat{r}_\phi \times \hat{h}_\phi]^2 I, \quad \text{(S31)}$$

where we used Eq. (S27) in order to write

$$\sqrt{\rho_\phi} K_\phi = \frac{\omega}{2\sqrt{2}} \left[\alpha c_\phi^+ + c_\phi^- (\hat{r}_\phi \cdot \hat{h}_\phi)\right] I +$$

$$+ \frac{\omega}{2\sqrt{2}} \left[c_\phi^+ \hat{h}_\phi + \alpha c_\phi^- \hat{r}_\phi + i c_\phi^- (\hat{r}_\phi \times \hat{h}_\phi)\right] \cdot \hat{\sigma} \quad \text{(S32)}$$

and

$$K_\phi \sqrt{\rho_\phi} = \frac{\omega}{2\sqrt{2}} \left[\alpha c_\phi^+ + c_\phi^- (\hat{r}_\phi \cdot \hat{h}_\phi)\right] I +$$

$$+ \frac{\omega}{2\sqrt{2}} \left[c_\phi^+ \hat{h}_\phi + \alpha c_\phi^- \hat{r}_\phi - i c_\phi^- (\hat{r}_\phi \times \hat{h}_\phi)\right] \cdot \hat{\sigma}. \quad \text{(S33)}$$

Therefore, the Wigner-Yanase skew-information is given by

$$I(\rho_\phi, K_\phi) = \frac{1}{2} (\omega c_\phi^-)^2 [\hat{r}_\phi \times \hat{h}_\phi]^2. \quad \text{(S34)}$$

Remember that the quantum system evolves under an unitary transformation which does not change the absolute value of Bloch sphere radius, i.e., $|\hat{r}_\phi| = |\hat{r}_0| = r_0$. Therefore, since $c_\phi^\pm = c_0^\pm$ and defining $\xi_\pm = 1 \pm \sqrt{1 - r_0^2}$, the Hellinger angle and Wigner-Yanase skew information becomes, respectively,

$$\cos(\mathcal{L}(\rho_0, \rho_\phi)) = \frac{1}{2} [\xi_+ + \xi_- (\hat{r}_\phi \cdot \hat{r}_0)] \quad \text{(S35)}$$

and

$$I(\rho_\phi, K_\phi) = \omega^2 \xi_\phi [\hat{r}_\phi \times \hat{h}_\phi]^2. \quad \text{(S36)}$$
