Pueraria lobata roots accumulate 3′-, 4′- and 7-O-methylated isoflavones and many of these methylated compounds exhibit various pharmacological activities. Either the 4′- or 7-O-methylation activity has been investigated at molecular levels in several legume species. However, the gene encoding the isoflavone 3′-O-methyltransferase (OMT) has not yet been isolated from any plant species. In this study, we reported the first cDNA encoding the isoflavone 3′-OMT from P. lobata (designated PIOMT4). Heterologous expressions in yeast and Escherichia coli cells showed that the gene product exhibits an enzyme activity to methylate the 3′-hydroxy group of the isoflavone substrate. The transcript abundance of PIOMT4 matches well with its enzymatic product in different organs of P. lobata and in the plant roots in response to methyl jasmonate elicitation. Integration of the biochemical with metabolic and transcript data supported the proposed function of PIOMT4. The identification of PIOMT4 would not only help to understand the isoflavonoid metabolism in P. lobata but also potentially provide an enzyme catalyst for methylating existing drug candidates to improve their hydrophobicity.

Keywords: methyltransferase, methyl jasmonate, isoflavone, 3′-O-methylation, Pueraria lobata

INTRODUCTION

Pueraria lobata (P. lobata) is a leguminous plant with important pharmacological activities. The medical effects of P. lobata are mostly attributed to the presence of a bioactive ingredient puerarin in its roots. As a C-glucosylated isoflavone, puerarin exhibits diverse medicinal properties, especially shows the pharmacological activities on cardiovascular and cerebrovascular diseases (Wong et al., 2011; Zhou et al., 2014). Despite of important bioactivities, the low liposolubility and gastrointestinal absorption of puerarin are serious drawbacks for applying it into clinic applications. The 3′-methoxy-puerarin was ever reported from P. lobata (Rong et al., 1998; Dubey et al., 2008). Compared to the puerarin itself, its derivative 3′-methoxy-puerarin owns higher liposolubility and antioxidant activity, and better intracellular compartmentation (Heim et al., 2002; Yang et al., 2004; Zhang et al., 2008; Jin et al., 2012). Recent studies showed an obvious protective effect of 3′-methoxy-puerarin on cerebral ischemic-reperfusion injury with some advantages over puerarin (Chen, 2007; Zhang et al., 2008; Han et al., 2009). Considering the better performance of the 3′-methoxy-puerarin, it deserves to identify...
the O-methyltransferase (OMT) in the biosynthetic pathway up to this compound. The methylation at the 3′-OH of the isoflavonoids is likely performed by an S-adenosyl-L-methionine (SAM)-dependent OMT, transferring a methyl group from the methyl donor SAM to the hydroxyl group of an acceptor molecule. In plants, OMTs are involved in the methylation of plant secondary metabolites, such as phenylpropanoids, flavonoids, and alkaloids (Ibrahim et al., 1998; Bureau et al., 2007). O-methylation of those secondary metabolites could reduce the chemical reactivity of their phenolic hydroxyl groups and increase their lipophilicity or antimicrobial activities (Zhu et al., 1994; Ibrahim et al., 1998; Bureau et al., 2007). From the view of plant physiology, this modifying process plays key roles in lignin biosynthesis, nitrogen fixations and disease resistances (Maxwell et al., 1993; Wu et al., 1997; Boerjan et al., 2003).

Several cDNA clones encoding isoflavonoid OMTs have recently been isolated and characterized. These include isoflavone 7-OMTs from Medicago sativa (He et al., 1998), M. truncatula (Deavours et al., 2006), and Glycyrhiza echinata (Akashi et al., 2003) and the 2,7,4′-trihydroxyisoflavone 4′-OMTs from M. truncatula (Deavours et al., 2006), G. echinata and Lotus japonicus (Akashi et al., 2003). However, to date, the isoflavonoid 3′-OMTs (13 OMTs) have not been isolated from any plant species and the methylation involved in the biosynthesis of 3′-methoxy-puerarin is not clear. Two possible routes to 3′-methoxy-puerarin are represented in Figure 1.

With the goal of isolating the isoflavone 3′-OMT genes, the RNA-sequenced data derived from the leaves and roots of P. lobata was extensively analyzed in this study, leading to the identification of two candidate OMTs (designated as PlOMT3 and PlOMT4). Both OMTs were expressed as recombinant proteins and their enzymatic functions were tested. One of the OMTs, PlOMT4, was found to methylate 3′-hydroxydaidzein to form 3′-methoxy-daidzein. The identification of PlOMT4 clarifies the isoflavone 3′-O-methylation process in P. lobata, and provides the basis for metabolic engineering of methylated isoflavonoid biosynthesis in other plants and microbial hosts.

**MATERIALS AND METHODS**

**Plant Materials and Chemicals**

The plant materials of P. lobata were collected from the Wuhan Botanic Garden, Chinese Academy of Sciences. The chemical standard 3′,4,7-trihydroxyisoflavone (3′-hydroxy-daizdein) was from Toronto Research Chemicals (Toronto, ON, Canada), and the standards prunein, biochanin A, calycosin, 3′-methoxy daidzein, chrysoeriol, and isoformononetin were purchased from BioBioPha Co., Ltd (Kunning, China). All the other chemicals were purchased from Shanghai Source Leaf Biological Technology Company (Shanghai, China). HPLC grade acetonitrile and methanol (Fisher Scientific) were used for high performance liquid chromatography (HPLC) and liquid chromatography–mass spectrometry (LC–MS). The restriction endonucleases were purchased from Takara Company (Takara, Dalian, China).

**Cloning the Full-Length cDNAs of OMT Candidates**

The transcriptome derived from the leaves and roots of P. lobata was constructed previously by our group (Wang et al., 2015). BLAST searches against several public databases were conducted in order to collect all the putative OMT sequences. A total of 108 unigenes were annotated as OMTs, of which only 42 unigenes were represented in a length of above one kilo base pairs. Out of these 42 putative OMTs, two candidates were identified as homologs to flavoid-3′-OMTs by BLASTx comparison to the NCBI non-redundant database. The two candidates, designated as PIOMT3 and PIOMT4, were chosen for this study.

The full-length cDNAs of PIOMT3 and PIOMT4 were amplified from the roots of P. lobata by standard RT-PCRs, and the amplified products were cloned into the pMD18-T vector (Takara) for sequencing confirm. The primers for the PCRs are listed in Supplementary Table S1.

**Phylogenetic Analysis**

The deduced amino acid sequences of the OMT candidates from P. lobata were aligned with other plant (iso)flavonoid methyltransferases with known functions using the CLUSTAL X Version 2.0 program (Larkin et al., 2007). Then the phylogenetic tree was constructed by the neighbor-joining method of the MEGA 6.0 program (Tamura et al., 2013). The bootstrap value was 1000. The information of the OMTs used in the phylogenetic analysis is summarized in Supplementary Table S2.

**Functional Analysis of OMT Candidates in Yeast**

The coding regions of PIOMT3 and PIOMT4 were amplified with gene specific primers (Supplementary Table S1) and cloned into the yeast expression vector pESC-HIS (Stratagene, La Jolla, CA, USA) to give the constructs pESC-HIS-PIOMT3 and pESC-HIS-PIOMT4, respectively. Both constructs, as well as the empty vector pESC-HIS as the control, were transferred into the yeast WAT11 strain (Pompon et al., 1996) using the lithium acetate method (Gietz and Woods, 2002). The resulting yeast strains were grown in His dropout liquid medium (Clontech, Palo, CA, USA) containing 2% (w/v) glucose at 30°C. After 24 h, the yeast cells were washed with sterile water and induced by His dropout liquid medium containing 2% (w/v) galactose supplemented with the substrates 3′-hydroxy-daizdein or 3′-hydroxy-puerarin at a final concentration of 100 µM. The yeast cultures were extracted with an equal volume of ethyl acetate after the induction. The ethyl acetate extracts were dried at room temperature and the residue was re-dissolved in 1 ml of methanol for HPLC analysis.

**In Vitro Enzyme Assays**

The coding region of PIOMT4 was cloned into the Escherichia coli expression vector pET28a (Novagen, Darmstadt, Germany) with its N-terminus fused with a 6 × HIS tag. The primers used for the cloning are listed in Supplementary Table S1. The expression of the recombinant PIOMT4 was induced with 0.5 mM isopropyl-ß-D-thiogalactopyranoside (IPTG) at
16°C for 14 h. The recombinant proteins were purified using HisPur™ Ni-NTA Resin (Thermo) following the provided protocol. The purified proteins were analyzed by SDS-PAGE and protein quantification was determined by Bradford assays.

To check the enzyme activity, enzyme assays were performed in a 200 μl of the reaction mixture consisting of 2 μg of the purified recombinant PIOMT4, 50 mM Tris–HCl (pH 8.0), 2 mM S-adenosyl methionine, 2 mM dithiothreitol (DTT) and 100 μM acceptor substrates. The reactions were carried out at 37°C for 20 min, stopped with the addition of 200 μl of methanol, and 15 μl of the reaction mixture was directly used for HPLC analysis.

**Gene Expression and Metabolite Analysis in *P. lobata***

*Porites lobata* materials (roots, leaves, and stems) were collected from open field, powdered under liquid nitrogen, and stored at −80°C for measuring the concentration of 3′-methoxydaidzein and the transcript abundance of *PlOMT4*. For the methyl jasmonate (MeJA) treatment, a final concentration of 100 μM MeJA was added in the liquid 1/2 MS medium where 1-month-old *P. lobata* seedlings were pre-equilibrated. The same volume of 0.001% ethanol was added into the liquid 1/2 MS medium as the mock control. Roots were collected after 6 h treatment for the gene expression analysis, and after
10 days treatment for the measurement of the concentration of 3′-methoxy-daidzein. To monitor the gene expression in different organs, total RNAs from the roots, stems, and leaves of *P. lobata* were isolated and treated with DNase I (Thermo) to remove genomic DNA contaminations. The first-strand cDNA was synthesized with the SuperScript III reverse-transcriptase (Invitrogen). Quantitative RT-PCR (qRT-PCR) was performed
on an ABI 7500 Fast Real-Time PCR Detection System with FastStart Universal SYBR Green Master mix (Rox; Roche, Mannheim, Germany). The PCR conditions were set as follows: 10 min of initial denaturation at 95°C, followed by 40 cycles of 95°C for 15 s and then 60°C for 1 min. All real-time PCRs were performed in three independent repeats. The primers used for the qRT-PCRs are listed in Supplementary Table S1. To measure the concentration of 3′-methoxy daidzein in different organs, 20 mg of plant materials were extracted with 1 ml of ethanol for three times. The ethanol extracts were air dried at room temperature and re-dissolved in 1 ml methanol for HPLC and LC–MS analysis.

**HPLC and LC–MS/MS Analysis**

For HPLC analyses, samples were detected by an LC-20AT instrument (Shimadzu, Kyoto, Japan) using an inertsil ODS-SP reverse phase column (250 mm × 4.6 mm, 5 µm) at 30°C. The Milli-Q water containing 0.4% phosphoric acid (solvent A) and HPLC-grade methanol (solvent B) were used as the mobile phase. The samples from the reactions with quercetin, kaempferol, and luteolin were separated using 65% B for 45 min at a flow rate of 0.8 ml/min. For other analyses, 0.1% (v/v) formic acid (A) and acetonitrile (B) were used as the mobile phase and samples were separated as follows: 0–30 min, 25–90% B; 30–35 min, 90–25% B; 35–40 min, 25% B and the flow rate was 0.8 ml min⁻¹. The detection wave length was set at 260 nm for isoflavones, 280 nm for liquiritigenin, 350 nm for apigenin and luteolin, and 370 nm for quercetin, kaempferol, and luteolin were separated using 65% B for 45 min. The detection wave length was set at 260 nm for isoflavones, 280 nm for liquiritigenin, 350 nm for apigenin and luteolin, and 370 nm for quercetin, kaempferol, and liquiritigenin. A calibration standard curve was made from different concentrations (5–100 µg ml⁻¹) of each chemical standard. LC–MS/MS analysis was acquired using Accela LC system with TSQ Quantum Access Max mass spectrometer (Thermo Scientific, Waltham, MA, USA) and electrospray ionization source. The analysis method was same as the HPLC analyses described above. The MS data was recorded in a positive ion mode with the ranges of m/z 50–500. Other parameters were set according to those described previously (Li et al., 2014).

**RESULTS**

**Isolation and Sequence Analysis of Putative OMT cDNA Candidates**

Retrieved from the *P. lobata* transcriptome, the full-length cDNAs of *PlOMT3* and *PlOMT4* were amplified by standard RT-PCRs, and their sequences were confirmed by sequencing and deposited in GenBank with the accession numbers of KP057886 and KP057887, respectively. The deduced amino acid sequences of the two OMT candidates showed 37.8% identity with each other. A phylogenetic tree was constructed to examine the relationships of the OMT candidates with other (iso)flavoid OMTs from other plant species whose functions are already known (Figure 2). *PlOMT3* and *PlOMT4* clustered with the flavonoid 3′-OMTs, suggesting that they are the candidates for the isoflavone 3′-O-methylation in *P. lobata*.

**In Vitro Enzyme Assays**

To examine the substrate specificity of *PlOMT4*, *PlOMT4* was successfully expressed in *E. coli* BL21 (DE3) cells and purified using HisPur™ Ni-NTA Resin (Thermo). The molecular weight

| Quercetin                        | 1142.3 ± 54.4              | 27.3 ± 1.3             |
| Kaempferol                       | 0                         | 0                      |

aRelative activity. The values are normalized with the most converted substrate 3′-hydroxy-daidzein as 100%.

**Functional Analysis of the OMT Candidates in Yeast**

To screen the activities of *PlOMT3* and *PlOMT4*, the two possible substrates 3′,4′,7-trihydroxyisoflavone (3′-hydroxy-daidzein) and 3′-hydroxy-puerarin, as shown in Figure 1, were added to the yeast cultures that expressed the recombinant PIOMTs. After the induction, the yeast cultures were extracted with ethyl acetate and the conversion of the substrates were examined by HPLC analysis. Notably, yeast cells expressing *PlOMT4* could convert the substrate 3′-hydroxy-daidzein to form the 3′-methoxy-daidzein (Figure 3A), indicating the 3′-O-methylation activity of *PlOMT4*. When the 3′-hydroxy-puerarin was added to the *PlOMT4*-expressed culture, no apparent conversion of the substrate was observed, in comparison with the control culture harboring the empty vector (data not shown). This data demonstrated that *PlOMT4* is able to methylate the 3′-hydroxy-daidzein but not accept the 3′-hydroxy-puerarin as the substrate. On the other hand, both the 3′-hydroxy-daidzein and 3′-hydroxy-puerarin were not significantly converted by the *PlOMT3*-expressed cultures (data not shown), suggesting that *PlOMT3* exhibited no activities toward these two substrates. The identity of the product 3′-methoxy-daidzein was confirmed with its standard using LC–MS analysis (Figure 3B).
The initial velocities of PIOMT4 with 3'-hydroxy-daidzein, luteolin, and quercetin were then compared. As shown in Table 1, the purified PIOMT4 exhibited the highest activity toward the isoflavone 3'-hydroxy-daidzin (100% relative activity, 4180.4 pkat/mg) with a relatively lower activity with the flavone luteolin (42.1% relative activity, 1759.5 pkat/mg) and the flavonol quercetin (27.3% relative activity, 1142.3 pkat/mg).

The Relevance of PIOMT4 Transcripts and Its Catalyzed Metabolites in *P. lobata*

The enzymatic product of PIOMT4, 3'-methoxy-daidzein, was mostly detected in the roots (133.9 ± 2.7 µg g⁻¹ dry weight), but was almost undetectable in its stems or leaves (Figure 5A). Consistent with the metabolite accumulation, the highest abundance of the PIOMT4 transcripts was observed in the roots whereas extremely low expressions were found in the stems and leaves (Figure 5B). Thus, the PIOMT4 transcripts match well with the accumulation pattern of its enzymatic product 3'-methoxy-daidzin in *P. lobata* in a spatial manner.

To further examine the relevance, the gene transcripts and the metabolite accumulation were monitored in an eliciting manner, by treating the 1-month-old *P. lobata* seedlings with...
The roots of 10 days-treated plants were used for metabolite analysis while 6 h-treated plants were collected for measuring the gene transcript levels. Apparently, the MeJA stimuli significantly increased the biosynthesis of the product 3′-methoxyl-daidzein in comparison with the mock control roots (Figure 5C). In line with the increase of the metabolite accumulation, the transcript concentration of PlOMT4 was also elevated in response to the MeJA treatment (Figure 5D). Taken together, the PlOMT4 transcript abundance correlates well with the accumulation of 3′-methoxy-daidzein in P. lobata, supporting its proposed biochemical role in vivo.

DISCUSSION

Many isoflavonoids are O-methylated with the methoxy residue enhancing their biological activities by altering hydrophobicity. The common sites for the methylation are the 3′-, 4′- and 7-positions of isoflavonoids (isoflavone carbon numbering). Either the 4′- or 7-methylation activity has been studied in several legume species (He et al., 1998; Akashi et al., 2003; Deavours et al., 2006), however, there was no report on the identification of a gene that encodes the isoflavone 3′-OMT (I3′OMT). Phytochemical work has elucidated the presence of 3′-O-methylated isoflavones in P. lobata, which allows it to be a suitable system for the molecular investigation of the isoflavone 3′-O-methylation. In this study, we isolated the first cDNA coding for an I3′OMT (PlOMT4) from P. lobata. Heterologous expression in yeast and E. coli showed that the gene product exhibited an enzyme activity to methylate the isoflavonol substrate 3′-hydroxy-daidzein at the 3′ position. The closest homolog of PlOMT4 in sequence databases (44.9% identity) is an enzyme with the flavonoid 3′-OMT (F3′OMT) activity from Mentha x piperita (Willits et al., 2004), which probably indicates that PlOMT4 might diverge from F3′OMTs. PlOMT4 preferentially methylates 3′-hydroxy-daidzein, it does have some but relatively lower activities on flavonoid compounds with 3′-hydroxy moiety, e.g., luteolin and quercetin (Figure 4). In particular, no detectable products resulted when the glycosyl derivatives of 3′-hydroxy-daidzein, i.e., 3′-hydroxy puerarin, were incubated with PlOMT4, suggesting that the isoflavone modifying reactions behave in strict orders and the 3′-O-methylation may proceed prior to glycosylations in vivo. The biochemical function of PlOMT4 allowed us to propose the route A shown in Figure 1 as the favorable pathway to 3′-methoxy-puerarin. By reference to the structural basis for plant isoflavone OMTs (Zubieta et al., 2001), the residues His-277, Asp-305, and Glu-337 of PlOMT4 might be important for its biochemical functions.

The gene expression of PlOMT4 in relation to the 3′-O-methylated isoflavonoid profile of P. lobata was studied. 3′-methoxy-daidzein are almost exclusively accumulated in P. lobata roots (Figure 5A), which is consistent with the distribution pattern of the PlOMT4 transcripts (Figure 5B). Moreover, in the P. lobata roots, the gene expression levels of PlOMT4 were increased by MeJA elicitation (Figure 5C), which also resulted in the increment of the 3′-O-methylated isoflavonoid biosynthesis (Figure 5D), suggesting that methylated isoflavonoids function as phytoalexins (Ibrahim et al., 1998; Bureau et al., 2007). The integration of the enzyme biochemical property in vitro, gene expression and metabolite accumulation in vivo strongly supported the proposed role of PlOMT4 in P. lobata.

CONCLUSION

PlOMT4 is the first I3′OMT identified from plants and it is likely responsible for the O-methylation of P. lobata isoflavones at C-3′ position. The identification of PlOMT4 should provide an opportunity to improve lipophilicity of isoflavonoids or other structure-like compounds by O-methylations at appropriate positions and in turn push forward for clinical applications.

AUTHOR CONTRIBUTIONS

YZ designed this study; JL performed the gene cloning and biochemical reactions; CL performed the MeJA treatment and provided the assistance in LC–MS or HPLC analysis; JG helped to collect the plant materials; JL and YZ wrote the manuscript.

FUNDING

This study was supported by the funding from the National Natural Science Foundation of China (grant numbers: 31300258 and 31170284) and the grant of One Hundred Talent Program of the CAS to YZ (grant number: 29Y129441R010444).
