Comparative Study of Neck Swelling by Clinical, Cytological and Histopathological Examination

Mohammad Idrish Ali1, Md. Mahmudul Huq2, Momenul Haque3, Kamrul Hasan Tarafder4

Abstract:
Objective: In this study 50 patients of neck swelling were studied to compare the findings with clinical diagnosis and histopathological report for its diagnostic compatibility.

Methods: This cross sectional study was done in Department of Otolaryngology – Head & Neck Surgery, Bangabandhu Sheikh Mujib Medical University, Dhaka from July 2015 to June 2017. Fine needle aspiration cytology, MRI, CT scan, and histopathological examination of postoperative specimen of neck swelling, analyzed data presented by various tables, graphs and figures.

Results: In the present series 50 cases of neck swelling were studied. Out of these 50 cases 19 were male and 31 were female. The male, female ratio was 1:1.63. Age range was 4 – 60 years with maximum frequency in the 4th decade with the 3rd and 2nd in the following suit. Most of the patient were poor. Clinical, cytological and histopathological diagnosis were available in all the cases. The three sorts of diagnoses were compared with each other. Histopathologically 12 cases were tubercular lymphadenopathy. Metastatic carcinoma and lymphoma 5 cases for each. Twelve were nodular goiter, 5 were thyroid carcinoma. Rest were benign, congenital and nonspecific inflammatory conditions. Correct diagnosis were made by FNAC in 45 cases. In the rest 5 cases smear were unsatisfactory in 2 cases and gives inconclusive result, remaining 3 were follicular neoplasm and no definitive result were made which were subsequently diagnosed by histopathological examination as a follicular adenoma in 1 and follicular carcinoma in 2. Sensitivity of FNAC in the diagnosis of neck masses were found 91% for tuberculosis, 100% for metastatic carcinoma also for salivary gland tumour. In case of nodular goiter sensitivity was 92%. But it is only 60% sensitive in case of thyroid malignancy, as FNAC can not demarcate clearly between follicular adenoma and follicular cell carcinoma. But its accuracy in diagnosing papillary cell carcinoma of thyroid was 100%.

Conclusion: Keeping the limitations in mind, FNAC can reduce substantially the need of open biopsy for histopathological examination. Last of all I wish to conclude the study with the popular saying of Stewart “Diagnosis by aspiration is as reliable as the combined intelligence of the clinician and pathologist makes it”.

Key words: Neck swelling, FNAC, cytological, histological study

Introduction:
Swelling in the head and neck region is one of the commonest clinical presentation in the otolaryngologic practice. Presence of a neck mass pose a diagnostic dilemma for the Otolaryngologist. A great number of disease manfesat as a palpable and /or visible swellings in the neck. These may congenital/developmental, inflammatory/reactionary or neoplastic (primary/secondary).

Each disease may have different mode of presentation. Conversely many diseases may present with similar symptoms. For this reasons diagnosis often becomes difficult in neck swelling. Many case of neck swelling may be diagnosed after a comprehensive history and a thorough clinical examination of the head neck. Further evaluation is done by hematological, cytological and imaging technique. Diagnosis is confirmed by histopathological examination of the specimen.

The medical profession must be emphatically remained of the frequency with which cervical metastasis may appear as the first and only symptom in cancer of the mouth, pharynx and larynx, less often elsewhere in the body. There can be no possibility of cure until the primary lesion is found. The immediate removal of a lymph node for diagnosis is never goes in the best interest of the patient. This procedure should be deferred and used only as a last diagnostic resort.1

For this reason now the head neck surgeon have advocated a careful search for primary malignancy before the presenting neck lump is biopsied. Open biopsy causes seedling of tumour cell into avascular plane making them resistant to curative radiotherapy or chemotherapy and the placing of a biopsy incision in an area which may subsequently be inappropriate for radical neck dissection flaps.2,3,4

Open biopsy is an invasive procedure requiring surgical skill and facilities. It is time consuming, costly and some time hospitalization and general anaesthesia may be needed. It delays the definitive treatment.1,3 Fine needle aspiration cytology is a simple procedure that can be done on an outpatient basis without local anaesthetic and gives rapid result. It is simple, cost-effective, less traumatic. The procedure may repeated several times to obtain adequate material for cytological analysis.5,7

In our country FNAC is gradually becoming more popular as a preoperative highly sensitive and cost effective diagnostic tools. Through this study I tried to find out spectrum of diseases producing neck swelling and their socio-demographic feature. Histopathological report has been taken as a confirmatory diagnostic test in all the cases and compared with the FNAC findings to find out its diagnostic reliability.

Methods:
This cross sectional study was done in Department of Otolaryngology –Head & Neck Surgery, Bangabandhu Sheikh Mujib Medical University, Dhaka from July 2015 to June 2017. Fine needle aspiration cytology, MRI, CT scan and histopathological examination of postoperative specimen of neck swelling, analyzed data presented by various tables, graphs and figures.

A total of 50 patients irrespective of age and sex with neck swelling randomly selected for the study who admitted in the Department of Otolaryngology -Head & Neck Surgery, Bangabandhu Sheikh Mujib Medical University Hospital Dhaka from July 2015 to June 2017.

This was a cross sectional study with a sample size 50. Method used in this study included. Clinical presentation, Fine needle aspirating cytology, Imaging of different types in selective cases, histopathological examination of postoperative specimen of neck swelling.

All information recorded in a standardized data collection sheet for the study. Then those were complied, analyzed and tabulated in order to obtain statistical and comprehensive results of the study.

Results and observation:

| Table I : | Age distribution of the patients. |
|-----------|-----------------------------------|
| Age group | No of cases | Percentage |
| 0 – 10    | 2           | 4          |
| 11 – 20   | 10          | 20         |
| 21 – 30   | 14          | 28         |
| 31 – 40   | 16          | 32         |
| 41 – 50   | 6           | 12         |
| 51 – 60   | 2           | 4          |
| Total     | 50          | 100        |
Table II:
Socioeconomic condition (n=50).

| Socioeconomic condition | No of cases | Percentage (%) |
|-------------------------|-------------|----------------|
| Poor                    | 30          | 60             |
| Middle                  | 15          | 30             |
| Affluent                | 5           | 10             |

Table III:
Clinical diagnosis of neck masses.

| Clinical diagnosis              | Disease                          | Total No of cases | Percentage(%) |
|--------------------------------|----------------------------------|-------------------|---------------|
| Cervical lymph adenopathy       | Tubercular lymph adenitis        | 19                | 38            |
|                                 | Metastatic carcinoma             | 5                 | 10            |
| Thyroid and related neck mass   | Goiter                           | 18                | 36            |
|                                 | Thyroglossal cyst                | 1                 | 2             |
| Salivary gland swelling         | Salivary gland tumour            | 4                 | 8             |
| Other congenital and developmental neck mass | Submental dermoid | 2 | 4 |
| Total                           |                                  | 50                | 100           |

Table IV:
FNAC diagnosis of neck masses

| Clinical diagnosis              | FNAC diagnosis                   | Total No of cases | Percentage(%) |
|--------------------------------|----------------------------------|-------------------|---------------|

|                    |             | Unsatisfactory smear | 1 | Tubercular lymph adenitis | 1           |
| Metastatic carcinoma | 5          | Metastatic carcinoma | 5 | Metastatic carcinoma | 5           |
Discussion:
Patients with palpable and or visible neck mass is a quite common presentation to an Otolaryngologist. So one should be rational and methodical for the diagnosis and management of such a patient. In the present study 1 tried to establish the role of FNAC in the management of such patients by establishing its diagnostic sensitivity and specificity in comparison with histopathological one, which is an accurate but cost effective, time consuming and also an invasive procedure.

In the present study we analyzed FNAC report of 50 cases. Here satisfactory smears were found in 47(94%) cases. In 3(6%) cases smears were unsatisfactory as they showed in adequate material, definitive diagnosis were made by histopathological examination. The rate of unsatisfactory smear in this study is in close proximity, to that of other studies.\(^8,10,11\)

In this study out of 50 cases 19(38%) were male and 31(62%) were female. The male to female ratio was 1:1.63. The male to female ratio is consistent with the study of other\(^8,11,12,13\).

In the present study age of the patient ranged from 4 to 65 years. The highest number of cases were found in 4\(^{th}\) decade. This was followed by 3\(^{rd}\) and 2\(^{nd}\) decades.

In this present series 40% of neck mass were of thyroid in origin which consistent with other studies.\(^3,14\)

In case of thyroid swelling out of 20 cases 12 (60%) cases were proved to be

---

### Table VII:

**Compare between clinical FNAC and histopathological diagnosis of thyroid and related disease.**

| Clinical diagnosis | No of cases | FNAC diagnosis | No of cases | Histopathological diagnosis | No of cases |
|-------------------|-------------|----------------|-------------|-----------------------------|-------------|
| Goiter            | 19          | Nodular goiter | 11          | Nodular goiter              | 11          |
| Papillary carcinoma of thyroid | 4          | Papillary carcinoma of thyroid | 4          |                             |             |
| Follicular neoplasm | 3          | Follicular carcinoma thyroid | 2          | Follicular adenoma          | 1           |
| Unsatisfactory smear | 1          | Nodular goiter | 1           |                             |             |
| Thyroglossal cyst | 1           | Thyroglossal cyst | 1          | Thyroglossal cyst          | 1           |

### Table VIII:

**Comparison between clinical, FNAC and histopathological diagnosis of salivary gland disease.**

| Clinical diagnosis | No of cases | FNAC diagnosis | No of cases | Histopathological diagnosis | No of cases |
|-------------------|-------------|----------------|-------------|-----------------------------|-------------|
| Salivary gland tumour | 4          | Pleomorphic adenoma | 3          | Pleomorphic adenoma         | 3           |
| Chronic submandibular sialoadenitis | 1          | Chronic submandibular sialoadenitis | 1          |                             |             |

---
multinodular goiter on histopathology and it is comparable with others.\textsuperscript{10,15}

Here FNAC shows highly sensitivity 91\% and specificity 100\% for nodular goiter. But in case of thyroid malignancy its sensitivity is very low 60\% as it can not demarcate clearly between follicular carcinoma and follicular adenoma. Although highly sensitive 100\% for papillary carcinoma of thyroid. It is comparable with others studies.\textsuperscript{15,16}

Commonest was Cervical lymphadenopathy 48\% of which tubercular lymphadenitis was 11 cases 46\%. This is consistent with the findings of some other studies\textsuperscript{17,18}. In this study the sensitivity was 91\% and specificity 100\% of FNAC for diagnosing tubercular lymphadenopathy is high and consistent with other studies\textsuperscript{8,11}.

In this study only one false negative result was found for tubercular lymphadenopathy by FNAC, may be due to inadequate aspirate or observer error.

Metastatic carcinoma was found in 21\% of total cervical lymphadenopathy and sensitivity and specificity for diagnosing such lesion is 100\% which was consistent with other studies.\textsuperscript{17,18,20,21,22}

In salivary gland lesions FNAC is very useful tool for diagnosis as it a nearly 100\% sensitive and specific.\textsuperscript{2,3,16}

The overall sensitivity and specificity of FNAC in relation to histopathology is 90\% and 100\% respectively which were compatible with other study.\textsuperscript{2}

The overall accuracy of FNAC was found in 90\% which is similar to that of other studies\textsuperscript{2,3,16,23}.

To obtain maximum benefit from the procedure, close co-operation between the surgeon and pathologist is very important. The role of an experienced cytopathologist is critical for correct diagnosis\textsuperscript{23}. Adequate amount of aspirate from the lesion is essential for accurate diagnosis. Operator must be skilled in performing aspiration. The pathologist must be experienced in cytologic interpretation of the material aspirated. Close clinicopathological correlation is absolutely necessary for useful clinical interpretation.\textsuperscript{7}

**Conclusion:**

Keeping the limitations in mind, FNAC can reduce substantially the need of open biopsy for histopathological examination. Last of all I wish to conclude the study with the popular saying of Stewart “Diagnosis by aspiration is as reliable as the combined intelligence of the clinician and pathologist makes it”.\textsuperscript{6}
