A geometric study of different curves for the rotor profiles of a twin-screw compressor

Antonio Giuffrida

Politecnico di Milano – Dipartimento di Energia, Via R. Lambruschini 4, 20156 Milano, Italy

Abstract. This paper presents the results of comparisons among some patented solutions for profiling the contours of the rotors in twin-screw compressors. Referring to a base case where all the generating curves are circumferences, patents suggesting to replace arcs of circumference with arcs of conic sections, i.e. parabola, ellipse and hyperbola, but even a straight line segment, are presented and guidelines for rotor profile construction are reported. After setting the size of the compressor, attention is paid to the inter-lobe area, as the sum of the area between two consecutive lobes in the male rotor and of the area of the groove in the female rotor. Actually, this area is strictly related to the volume displacement. Limited to the current case study, the profile including an elliptic segment seems to be the preferable solution for higher inter-lobe area, then for higher displacement, though a number of considerations should be necessary for a broader context.

1 Introduction

Compressors are mechanical devices used to raise the pressure of gases or vapours. Though similar to pumps, the volumetric flow rate delivered by a compressor reduces from inlet to outlet, as gases or vapours are compressible fluids. There are dynamic- and positive-displacement-type compressors. In particular, the twin-screw compressor is a positive-displacement rotary machine where two helically lobed rotors rotate within a fixed housing, as sketched in Fig. 1. This compressor has no suction or discharge valves and no clearance volume. Besides, a correct arrangement of port timing results in the built-in volume ratio of the compressor [1].

1.2 Bibliographic survey

Literature is rich of works dealing with screw compressors from both theoretical and experimental points of view. Two interesting review works can be referred here as concerns mathematical models for performance calculation [2] and experimental researches [3], respectively. Rotor profile shapes and machining precision affect both performance and efficiency. Focusing on the methods for generating the rotor profiles, three solutions are detailed in literature: (i) generation from a given curve on one rotor [4, 5], (ii) generation from a meshing line [6, 7] and (iii) generation from a rack [5, 8, 9]. The first method is a
prevalent practice, as reported in a number of patents [10-17], dealing with primary curves on one rotor, generating conjugate curves on the other one. Any curve can be used as the primary one, but the circumference is the most common [10-12]. Nevertheless, arcs of other conic sections, namely arcs of parabola [13], ellipse [14] and hyperbola [15], but even a straight line segment [16], can be used to replace arcs of circumference. As a matter of fact, the generation method starting from a curve defined on one rotor is older than the other two [6-9], but it is a still current methodology if one considers the recent application by a German manufacturer [17].

![Fig. 1. Exploded view of a twin-screw compressor with particular reference to male and female rotors, housing and details of the discharge port [7].](image)

1.2 Objective of the work

This paper follows a previous work oriented to calculate the main geometric characteristics of twin-screw compressors [18]. According to the actual size of a machine for compressed air application, after setting the lobe numbers in the male and female rotors (4 and 6, respectively), the inner and outer diameters of both rotors, the center distance between the rotors, the axial length as well as the wrap angle (see Table 1), this paper aims at comparing different patented frames [13-16] for the highest inter-lobe area, then the highest volume displacement.

Actually, a review of patents dealing with twin-screw compressors has been reported by Stosic et al. [5], outlining a number of cases. Nevertheless, neither Stosic et al. [5] nor other literature works thoroughly present numerical comparisons of specific case studies. This work focuses on the largest possible inter-lobe area, considering the same axial rotor length and the same wrap angle. In detail, neither a revision of the lobe numbers in the rotors, nor an increase in the rotor profile depth has been considered. The first solution may be trivial, as a 3/5 configuration [19-21], i.e. 3 lobes in the male rotor and 5 grooves in the female rotor, is actually preferable to a 4/6 configuration. In addition, deeper profiles for better displacement have been recently studied by Stosic et al. [22] by reducing the center distance between the rotors, which is a fixed geometric parameter in the present work.

The next section presents four patented profiles, along with a reference profile studied in detail in a former work [18], where specific details about the design method have been reported. Focusing on the male rotor, as highlighted in the following, all the frames are similar as regards the flat side. Thus, the comparison is fair because the variation in the rotor profile refers to the round side of the lobe.

2 Rotor profile investigation

This section presents the demonstrator profile [5], starting from the reference geometry of a twin-screw compressor investigated in a previous work [18], along with other four
patented solutions [13-16]. In detail, the new rotor profiles are investigated as possible improvements in terms of inter-lobe area.

2.1 Reference profile

The demonstrator profile is a rotor generated ‘N’ profile [5]. This specific profile is chosen as the reference case, as formerly investigated [18]. The curves generating the lobe profile of the demonstrator are given on the male rotor for the most part. Actually, this rotor profile, as well as the others in the following, is differentiable in every point. In detail, the profile is divided into a few segments, as shown in Fig. 2a:

- the segment $A_1B_1$ (in black in Fig. 2a) on the male profile is an arc of circumference with radius $r_1$. Its center lies on the line from $O_1$ to $O_2$, centers of the two rotors; the segment $A_2B_2$ on the female profile is the corresponding conjugate;
- the segment $B_1C_1$ (in magenta in Fig. 2a) on the male profile is an arc of circumference with radius $r_3$. Its center lies on the line from $O_1$ to $C_1$; the segment $B_2C_2$ on the female profile is the corresponding conjugate;
- the segment $A_1D_1$ (in red in Fig. 2a) on the male profile is an arc of circumference with radius $r_2$. Its center lies on the line from $O_1$ to $O_2$; the segment $A_2D_2$ on the female profile is the corresponding conjugate;
- the segment $D_2E_2$ (in blue in Fig. 2a) on the female profile is an arc of circumference with radius $r_4$. Its center lies on the line from $O_2$ to $E_2$; the segment $D_1E_1$ on the male profile is the corresponding conjugate.

![Fig. 2. Contours (a) of male lobe and female groove based on the demonstrator frame [5] and plot (b) of the two rotors with the lobes shaped according to the demonstrator profile.](image)

The main geometry of the compressor investigated in this paper is reported in Table 1. As regards the specific parameters for shaping the rotor, three values have been set: $r_2 = 1\ mm$, $r_3 = 3\ mm$ and $r_4 = 2\ mm$ [18]. In detail, $r_1$ in segment $A_1B_1$ results from the geometry construction. Differently from the original frame [5], the female lobe has been strengthened by maintaining the outer diameter constant for an angular range of $1.5^\circ$ (in green in Fig. 2a, on the right of $C_2$). Such a feature is always included in the next profiles despite the specific generating curves [13-16].

2.2 ‘P’ profile

The second profile case refers to the patent of Kasuya et al. [13], where an arc of parabola is introduced. In this case, the primary curves generating the lobe profiles are given on the female rotor for the most part. As shown in Fig. 3a, the profile is divided into a few segments:
Table 1. Main geometry for the investigated compressor.

| Parameter                                      | Value  |
|------------------------------------------------|--------|
| Lobe number of the male rotor                  | 4      |
| Lobe number of the female rotor                | 6      |
| Outer diameter of the male rotor               | 90 mm  |
| Outer diameter of the female rotor             | 85 mm  |
| Inner diameter of the male rotor               | 51 mm  |
| Inner diameter of the female rotor             | 46 mm  |
| Wrap angle of the male rotor                   | 300°   |
| Wrap angle of the female rotor                 | 200°   |
| Center distance between the rotors             | 68 mm  |
| Length of the rotors                           | 140 mm |

- the segment A₂B₂ (in black in Fig. 3a) on the female profile is a portion of parabola whose axis lies on the line from O₁ to O₂, centers of the two rotors; the segment A₁B₁ on the male profile is its corresponding conjugate;
- the segment B₂C₂ (in magenta in Fig. 3a) on the female profile is an arc of circumference with radius r₃P. Its center lies inside the line from O₂ to C₂; the segment B₁C₁ on the male profile is its corresponding conjugate;
- the segment A₁D₁ (in red in Fig. 3a) on the male profile is an arc of circumference with radius r₂P. Its center lies on the line from O₁ to O₂; the segment A₂D₂ on the female profile is its corresponding conjugate;
- the segment D₂E₂ (in blue in Fig. 3a) on the female profile is an arc of circumference with radius r₄P. Its center lies on the line from O₂ to E₂; the segment D₁E₁ on the male profile is its corresponding conjugate.

Comparing such ‘P’ profile with the previous demonstrator, it is possible to realize that the main difference focuses on the round side of the male rotor. As a matter of fact, the flat side is the same, as well as the corresponding conjugate counterpart in the female groove.

Fig. 3. Contours (a) of male lobe and female groove based on the ‘P’ frame [13] and plot (b) of the two rotors with the lobes shaped according to the ‘P’ profile.
The main geometry for this ‘P’ case is the one reported in Table 1. In detail, the same values of \( r_2 \) and \( r_4 \) introduced for the reference profile have been assumed for \( r_{2P} \) and \( r_{4P} \). The shape of the parabolic arc from \( A_2 \) to \( B_2 \) in Figs. 3a and 3b results from the geometry construction after setting \( r_{3P} = 2.904 \) mm, which is the value of the radius of curvature of the segment \( B_2C_2 \) in the reference profile at point \( C_2 \). Actually, the radius \( r_{3P} \) is a degree of freedom. After ‘P’ profile equation implementation in the MATLAB® environment, the plot in Fig. 3b shows the new male and female rotors, along with the two pitch circumferences and the inner contour of the housing.

### 2.3 ‘E’ profile

The third profile case refers to the patent of Lee [14], where an arc of ellipse is introduced. Differently from the previous case, the primary curves generating the lobe profile are given on the male rotor for the most part, similarly to the demonstrator case. As shown in Fig. 4a, the profile is divided into a few segments:

- the segment \( A_1B_1 \) (in black in Fig. 4a) on the male profile is a quarter of ellipse. The focal points lie on the line from \( O_1 \) to \( O_2 \), centers of the two rotors, and point \( B_1 \) lies on the pitch circumference [14]; the segment \( A_2B_2 \) on the female profile is the corresponding conjugate;
- the segment \( B_1C_1 \) (in magenta in Fig. 4a) on the male profile is an arc of circumference with radius \( r_{3E} \). Its center lies on the line from \( O_1 \) to \( C_1 \). Since point \( B_1 \) lies on the pitch circumference [14], \( r_{3E} \) results from a specific frame and cannot be set arbitrarily; the segment \( B_2C_2 \) on the female profile is the corresponding conjugate;
- the segment \( A_1D_1 \) (in red in Fig. 4a) on the male profile is an arc of circumference with radius \( r_{2E} \). Its center lies on the line from \( O_1 \) to \( O_2 \); the segment \( A_2D_2 \) on the female profile is the corresponding conjugate;
- the segment \( D_2E_2 \) (in blue in Fig. 4a) on the female profile is an arc of circumference with radius \( r_{4E} \). Its center lies on the line from \( O_2 \) to \( E_2 \); the segment \( D_1E_1 \) on the male profile is the corresponding conjugate.

Comparing such ‘E’ profile with the previous two, it is possible to realize that the main difference focuses on the round side of the male rotor, as the flat side is the same. Similar considerations can be made for the female counterpart.

![Fig. 4. Contours (a) of male lobe and female groove based on the ‘E’ frame [14] and plot (b) of the two rotors with the lobes shaped according to the ‘E’ profile.](image-url)
‘E’ profile equation implementation in the MATLAB® environment, the plot in Fig. 4b shows the new male and female rotors, along with the two pitch circumferences and the inner contour of the housing. In this case, thicker lobes in the female rotor compared to Figs. 3b and 4b can be immediately appreciated.

2.4 ‘H’ profile

The fourth profile case refers to the patent of Chen [15], where an arc of hyperbola is introduced. Similarly to the ‘P’ frame, the primary curves generating the lobe profile are given on the female rotor for the most part, differently from the demonstrator and the ‘E’ profiles. As shown in Fig. 5a, the profile is divided into a few segments:

- the segment A2B2 (in black in Fig. 5a) on the female profile is a portion of hyperbola whose axis lies on the line from O1 to O2, centers of the two rotors; the segment A1B1 on the male profile is the corresponding conjugate;
- the segment B2C2 (in magenta in Fig. 5a) on the female profile is an arc of circumference with radius r3H. Its center lies inside the line from O2 to C2; the segment B1C1 on the male profile is the corresponding conjugate;
- the segment A1D1 (in red in Fig. 5a) on the male profile is an arc of circumference with radius r2H. Its center lies on the line from O1 to O2; the segment A2D2 on the female profile is the corresponding conjugate;
- the segment D2E2 (in blue in Fig. 5a) on the female profile is an arc of circumference with radius r4H. Its center lies on the line from O2 to E2; the segment D1E1 on the male profile is the corresponding conjugate.

Comparing such ‘H’ profile with the previous demonstrator, ‘P’ and ‘E’ frames, the main difference concerns the round side of the male rotor, as the flat side is always the same.

According to the main geometry reported in Table 1, the same values of r2 and r4 introduced for the reference profile have been assumed for r2H and r4H. The shape of the hyperbolic arc results from the geometry construction after setting r3H = 2.904 mm, which is the value of the radius of curvature of the segment B2C2 of the reference profile at point C2. Actually, the radius r3H is a degree of freedom, like r3P for the ‘P’ profile. After ‘H’ profile equation implementation in the MATLAB® environment, the plot in Fig. 5b shows the new male and female rotors, along with the two pitch circumferences and the inner contour of the housing.

![Fig. 5. Contours (a) of male lobe and female groove based on the ‘H’ frame [15] and plot (b) of the two rotors with the lobes shaped according to the ‘H’ profile.](image-url)
2.5 ‘S’ profile

The fifth profile case refers to the patent of Bammert [16]. Here, a straight line segment, tangent to two circumference arcs, is introduced instead of specific conic sections as adopted in the previous cases [13-15]. Indeed, the patent under consideration is a prior document compared to the others [13-15] and details an early ‘Sigma’ profile as reported by Stosic et al. [5]. Similarly to the ‘P’ and ‘H’ frames, the primary curves generating lobe and groove contours are given on the female rotor for the most part, differently from the demonstrator and the ‘E’ profiles. As shown in Fig. 6a, the profile is divided into a few segments:

- the segment A2B2 (in black in Fig. 6a) on the female profile is an arc of circumference with radius r1S whose center lies on the line from O1 to O2, centers of the two rotors; the segment A1B1 on the male profile is the corresponding conjugate;
- the segment B2C2 (in red in Fig. 6a) on the female profile is a section of straight line, which is tangent in B2 to the previous circumference arc A2B2 and in C2 to the next circumference arc C2D2; the segment B1C1 on the male profile is the corresponding conjugate;
- the segment C2D2 (in magenta in Fig. 6a) on the female profile is an arc of circumference with radius r3S. Its center lies inside the line from O2 to D2; the segment C1D1 on the male profile is the corresponding conjugate;
- the segment A1E1 (in red in Fig. 6a) on the male profile is an arc of circumference with radius r2S. Its center lies on the line from O1 to O2; the segment A2E2 on the female profile is the corresponding conjugate;
- the segment E2F2 (in blue in Fig. 6a) on the female profile is an arc of circumference with radius r4S. Its center lies on the line from O2 to F2; the segment E1F1 on the male profile is the corresponding conjugate.

Comparing such ‘S’ profile with the previous demonstrator, ‘P’, ‘E’ and ‘H’ frames, the main difference always concerns the round side of the male rotor, as the flat side is simply the same.

Fig. 6. Contours (a) of male lobe and female groove based on the ‘S’ frame [16] and plot (b) of the two rotors with the lobes shaped according to the ‘S’ profile.

Based on the main geometry in Table 1, the same values of r2 and r4 introduced for the reference profile have been assumed for r2S and r4S. As regards the generating segments from A2 to D2 on the female rotor, r1S = 24.285 mm, which is the value of the radius of curvature of the segment A2B2 of the reference profile at point A2 and r3S = 2.904 mm, which is the value of the radius of curvature of the segment B2C2 of the reference profile at point C2. Length and slope of the segment from B2 to C2 result from the construction of this specific ‘S’ profile. Actually, both r1S and r3S are degrees of freedom, so the ‘S’ profile [16]
seems to be more flexible than the previous ones [13-15]. After ‘S’ profile equation implementation in the MATLAB® environment, the plot in Fig. 6b shows the new male and female rotors, along with the two pitch circumferences and the inner contour of the housing.

3 Inter-lobe areas and other considerations

The previous paragraphs, focusing on specific patented profiles, have introduced the geometric construction of different rotor shapes and qualitatively compared them with the reference case. All the five profile cases have the same shape for the flat side of the male rotor profile and the corresponding female conjugate. Indeed, other patented profiles use portions of conic sections. As an example, arcs of parabola are used by Hough et al. [23], but the flat side of the resulting male rotor profile differs from the ones presented in the previous section, where the flat side of the male rotor always has the same shape. Thus, the comparison of the five cases under investigation is fully fair.

Referring to each specific profile, the inter-lobe area evolution has been calculated based on the energy method, whose application to gear pumps for fluid power applications is widely reported in the literature [24-26]. In detail, according to the calculations resulting from the geometric approach adopted in a previous work [18], Table 2 reports the inter-lobe areas for the analyzed cases. After comparing the results, the ‘E’ profile is a very interesting solution in order to increase the volume displacement of the compressor. As a matter of fact, an improvement of around 3% compared to the reference case seems to be possible. On the other hand, slight reductions of the inter-lobe area can be appreciated for the other three profiles (‘P’, ‘H’ and ‘S’). In detail, they are less than 1%, so preliminary considerations based on volumetric improvements may be misleading and should be revised according to further analyses of the twin-screw machine. In particular, the results in Table 2 are limited to the specific size reported in Table 1, without investigating possible improvements arising from a parametric analysis on profile parameters as formerly proposed by Bergadano et al. [18]. Nevertheless, the superiority of the ‘H’ profile in terms of volume displacement, as reported elsewhere [5], cannot be confirmed here, as three solutions seem to be better than the ‘H’ design, limited to this case study and the related calculation hypotheses.

| Profile | Inter-lobe Area (mm²) |
|---------|-----------------------|
| Reference | 995.1 |
| ‘P’ profile | 985.9 |
| ‘E’ profile | 1024.9 |
| ‘H’ profile | 990.1 |
| ‘S’ profile | 992.5 |

Fig. 7 shows another geometric result, as previously anticipated when introducing the ‘E’ profile. The difference in the circular lobe thickness between the patented profiles [13-16] and the demonstrator is reported as a function of the male/female rotor radius. Looking at the results, only the ‘E’ profile presents less thick lobes for the male rotor and thicker lobes for the female rotor, compared to the reference case, differently from ‘P’, ‘H’ and ‘S’ profiles.
These results related to both inter-lobe areas and lobe thickness are consistent with the studies by Stosic et al. [5, 27]. In particular, the lower thickness of the male lobe according to the ‘E’ design should not affect its mechanical strength. Of course, the higher the volume displacement, the larger the flow rate delivery, though attention should be paid to the fluid leakages. On one hand, considering the flat side of the male lobe is always the same for the analyzed profiles [13-16], as well as for the female counterpart, no variations can be calculated for the blow-hole [18], which is the same for all the cases here investigated after radii $r_2$ and $r_4$ have been set. On the other hand, attention should be also paid to the leakage paths across the sealing line. As a matter of fact, higher volume displacements usually result in longer sealing lines [5, 18, 27] and the ‘E’ profile investigated in this study is no exception. Actually, the calculated length of the sealing line for the ‘E’ profile is 4.65% greater than the reference profile and 5.76% greater than the ‘H’ profile, which has the shorter sealing line limited to the investigated cases. In addition, when calculating the ratio between the length of the sealing line and the inter-lobe area, the highest value occurs precisely for the ‘E’ profile (120.4 m$^{-1}$) and the lowest for the ‘H’ profile (117.9 m$^{-1}$), suggesting that a simple geometric comparison may be not sufficient to select the proper profile.

![Fig. 7. Differences in lobe thickness between the ‘P’ and the demonstrator profiles (a), the ‘E’ and the demonstrator profiles (b), the ‘H’ and the demonstrator profiles (c), the ‘S’ and the demonstrator profiles (d). Thick traces refer to the male lobe and thin traces refer to the female lobe.](image)

4 Conclusions

This work has presented a comparison among some solutions for profiling the rotor contours of twin-screw compressors, compared to a reference case, previously analysed in detail [18]. Four patented profiles have been considered in this work as case studies, in
order to highlight the better frame for the higher inter-lobe area, i.e. the higher volume
displacement. The profile adopting an elliptic segment is the preferable solution for such a
purpose, though limited to the current case study. However, other considerations for a
broader context should be made as regards the flow rate delivery, with particular reference
to the leakage paths. As a matter of fact, a mathematical modelling for performance
calculation of screw compressor processes [2] is really necessary to understand both the
strong and weak points of one profile over another.
