Abstract

Background

To date, the genetic contribution to Parkinson’s disease (PD) remains unclear. Mutations in the collagen type VI alpha 3 (COL6A3) gene were recently identified as a cause of isolated dystonia. Since PD and dystonia are closely related disorders with shared clinical and genetic characteristics, we explored the association between COL6A3 and PD in a Chinese cohort.

Methods

We performed genetic screening of COL6A3 in a Chinese cohort of 173 patients with sporadic PD and 200 healthy controls. We identified variants that are likely to have pathogenic effects based on: 1) a minor allele frequency of < 0.01; and 2) the variant being recognized as deleterious by at least 15 different in silico predicting tools. Finally, we tested the aggregate burden of COL6A3 on PD via SKAT-O analysis.

Results

First, we found compound heterozygous COL6A3 gene mutations in one early-onset PD patient. Then, we explored whether COL6A3 variants contributed to increased risk of developing PD in a Chinese population. We detected 21 rare non-synonymous variants. Pathogenicity predictions identified seven novel non-synonymous variants as likely to be pathogenic. SKAT-O analysis further revealed that an aggregate burden of variants in COL6A3 contributes to PD (p = 0.03).

Conclusion

An increased aggregate burden of the COL6A3 gene was detected in patients with PD.

Background

Parkinson’s disease (PD) is the second most common neurodegenerative disease in the world, affecting approximately 2–3% of the population ≥ 65 years of age [1, 2]. The disease is characterized by multiple symptoms, grouped as motor symptoms such as bradykinesia, resting tremor and rigidity [3], and non-motor symptoms such as depression, apathy and sleep disorders [4]. The precise cause of PD is currently unknown, although scientists generally believe that it is a result of both genetic and environmental factors.

The collagen type VI alpha 3 (COL6A3) gene, encoding the collagen alpha-3(VI) chain, is recognized as being associated with muscular dystrophy [5]. Recently, Zech et al. found that loss-of-function mutations of COL6A3 cause autosomal recessive isolated dystonia [6], a movement disorder characterized by intermittent muscle contractions [7, 8]. Dystonia occurs either as an isolated condition or accompanied by other disorders such as Parkinsonism, and is closely linked to PD. Dystonia is seen in over 30% of patients with PD and often even before the onset of Parkinsonism [9]. Dystonia is common in PD patients whose age of onset is < 40, and it most commonly affects the lower limbs [10, 11].

Several previous studies have found that patients carrying mutations in dystonia-related genes, such as GCH1 and TH, displayed features of Parkinsonism in addition to dystonia [12, 13]. Even in patients with pure Parkinsonism (without dystonia), the frequency of rare GCH1 variants were higher than in controls, indicating that variants in GCH1 may be associated with a higher risk of PD [14]. Extending current understandings of the COL6A3 gene, we report here compound heterozygous mutations in the COL6A3 gene in an early-onset PD patient. To further investigate the relationship between COL6A3 and PD, we screened for COL6A3 mutations in a Chinese cohort.

Methods And Materials

Subjects

A total of 173 cases of sporadic PD (diagnosed by a specialist in movement disorders following the MDS diagnostic criteria [3]) were recruited from the Second Affiliated Hospital of Medicine College, Zhejiang University, between January 2016 and June 2019. The index patient was a 43 years old male with no remarkable medical history or family history from Chinese Han population. In addition, 200 demographically-matched healthy controls were included.
Sample preparation and sequencing

Genomic DNA of the patients and controls was isolated from peripheral leukocytes using standard protocols. Whole sequences of the selected genes were captured with a SureSelect Human All Exon 50 Mb kit (Agilent Technologies). Sequencing was conducted as 150 bp paired-end runs on an Illumina Nova Seq 5000 system to a 300-fold depth of coverage. AfterQC[15] was used to process the raw data, including filtering out and trimming bad reads. Then, sequence reads were mapped to the human genome assembly GRCh37/hg19 using Burrows–Wheeler Aligner 16. ANNOVAR software was used to annotate the variants [16].

Criteria for pathogenicity of rare variants

To determine the deleterious variants of the \textit{COL6A3} gene, we filtered the variants found in our cohort using the following algorithm: 1) identify rare non-synonymous variants with a minor allele frequency of < 1% or “not available” in the Genome Aggregation Database East Asia [17] or the 1,000 Genomes Project [18]. Variants in the exon region were selected for further evaluation since they are more likely to have a negative effect on protein structure and function. 2) Use an integrated genetic and clinical database, the VarCards [19], for preliminary evaluation of the deleterious effect of the variants. Those variants predicted to be deleterious by at least 15 tools were considered potentially pathogenic. 3) Screen the variants in the control population.

Amino acid conservation analysis using multiple sequence alignment of \textit{COL6A3} protein sequences from different species was performed by ClustalX [20].

The 3D protein structures of the wild-type and variant proteins were predicted using Phyre2 [21] and visualized by PyMOL (The PyMOL Molecular Graphics System v2.0, Schrödinger, LLC). The effects of missense variants on protein structure were evaluated by Missense3D [22].

Statistical analysis

Before genetic analysis was performed, we carried out a Hardy–Weinberg Equilibrium (HWE) test via chi-squared test in the control group [23].

The sequence kernel association test optimal (SKAT-O, [24]) was implemented in R(version3.6.2, The R Foundation) using SKAT v2.0 to determine the difference between PD cases and controls in aggregate burden of rare \textit{COL6A3} gene variants.

Results

General information

Our index patient was a 43-year-old male with no remarkable past medical history. He developed a mild gait difficulty four years ago. His symptoms worsened over time and he gradually experienced muscle rigidity and clumsiness. Physical examination showed bilateral rigidity and bradykinesia without resting tremor or dystonia. DAT-PET revealed reduced tracer uptake bilaterally, mainly in the putamen, indicating nigrostriatal dopaminergic denervation. He responded well to levodopa therapy (300 mg/day). Whole-exome sequencing revealed two heterozygous recessive variants in the \textit{COL6A3} gene (p.A769T and p.D1674N). The p.A769T variant was reported on ClinVar with an interpretation of uncertain significance or likely benign, while the other variant p.D1674N was not previously reported on ClinVar. His pedigree chart and DAT-PET scan result are shown in Fig. 1.

Our cohort consisted of 173 idiopathic PD patients. Of these, 81 were defined as early onset PD (EOPD) with age at onset of 44.32 ± 5.46 years old. The remaining 92 were late onset PD (LOPD) with age at onset 59.17 ± 7.72 years old (Table 1).

|                     | N(F:M) | Age at on set ± SD |
|---------------------|--------|--------------------|
| PD                  |        |                    |
| EOPD                | 39:42  | 44.32 ± 5.46       | 52.22 ± 10.03 |
| LOPD                | 41:51  | 59.17 ± 7.72       |
| control             |        | 102:98             |

Table 1
summary of basic information of PD and Control
EOPD is defined in this study as PD patients whose age of onset is \( \leq 50 \), while LOPD is defined as patients whose age of onset is \( > 50 \).

**Variant analysis**

Most genotype frequencies in the control group were in agreement with the HWE principle \( (p > 0.05) \), indicating our data are free from sample level substructure and genotyping error.

According to our filtering procedure, 21 rare non-synonymous variants were selected (Table 2). *In silico* predicting tools further identified seven patients with variants of COL6A3 likely to have a pathogenic effect (Table 3). Of these patients, four were in the EOPD group and the other three in the LOPD group. Only two patients with the variants p.A1031T and p.R1656Q presented with foot dystonia. Detailed clinical features of the other patients are shown in Table 3.

**Table 2 Information of rare variants identified in our cohort.**

| 33   | c.5692G > A       | G1898R            | 1/346        | 0/400            | male   | 56           | 7                | hallucinations, dementia, insomnia and slurred speech, bradykinesia and rigidity | none            | not good        |

Multiple sequence alignment by ClustalX showed that four variants were fully conserved (p.R928H, p.A1031T, p.G1898R and p.F1236S), indicating variants in these loci may have an effect on protein function (Fig. 2). However, 3D structure prediction of all the variants and the wild type detected no structural alterations (Fig. 3).

Of the seven variants we identified, two were previously reported on Clinvar. These two, rs114322958 and rs545819982, were recorded as benign and uncertain significance respectively for Bethlem myopathy.

SKAT-O analysis showed significant associations for the COL6A3 gene between PD patients and controls considering the likely damaging variant we identified above (P = 0.03).

### Discussion

The COL6A3 gene, encodes a component of type VI collagen, which is a flexible protein in the extracellular space. Previous studies have shown that mutation in COL6A genes (COL6A 1–3) is associated with Bethlem myopathy and Ullrich congenital muscular dystrophy. Now it is believed that these two diseases may be at one end of a phenotypic spectrum, mainly manifesting as muscle weakness and joint contractures.

Using whole-exome sequencing, Zech et al. recently reported recessive mutations in the COL6A3 gene in association with early-onset isolated dystonia. Clinical symptoms varied from focal dystonia, mild cervical dystonia, mild segmental dystonia and mild generalized dystonia to severe generalized dystonia. A previous study by Zech et al. detected five variants in five early-onset isolated dystonia patients, and found that at least one of the homozygous variants is located in exon 41 or 42. Furthermore, experiments in Zebrafish embryos and the mouse brain showed the exon skipping mutation in exon 41 in resulted in the development of segmental dystonia, without any muscular disease. Thus, they concluded that variants in COL6A3 may cause dystonia by affecting the extracellular matrix in the central nervous system, and that exons 41 and 42 are hotspots for mutation. However, the role of COL6A3 mutation in isolated dystonia had been challenged by Lohmann et al., who screened 955 patients with combined or isolated dystonia. They only identified one biallelic mutation in a patient with Parkinsonism and dystonia. This patient also carried homozygous mutations in the PINK1 gene, which are considered to be associated with early-onset Parkinsonism. Panda et al. also reported an early-onset isolated dystonia case with two pathogenic compound heterozygous loss-of-function mutations in exons 10 and 12.
Dystonia can be seen in both early- and late-onset PD patients, and can occur precede or after parkinsonism[29]. Two of the seven patients we identified carrying these possible deleterious variants presented with dystonia feature. We assume it may be due to the relatively short disease duration (mean 3.7 years).

In the present study, we reported two recessive mutations (p.A769T and p.D1674N) in the COL6A3 gene in our index PD patient. The variants are located in exons 6 and 8, in contrast to the previous study. However, since the patient currently shows no symptoms of dystonia, we assume variants in some region of COL6A3 may have an association with PD. As a result, we identified seven likely pathogenic variants in COL6A3, but none of them were located in exon 41 or 42 as previously reported. In addition, two patients who carried the variants p.A1031T and p.R1656Q presented with dystonia. SKAT-O analysis showed significant aggregate burden between patients and controls, indicating that variants in the COL6A3 gene may increase the genetic burden in PD.

Conventional single-variant test may not be appropriate in our cohort because of small sample size and variants’ low frequencies. Thus we adapted the SKAT-O to investigate the associations of variants and phenotypes. SKAT-O combined the burden test and SKAT to maximize the power[30]. Besides, by way of small-sample adjustment method of SKAT-O, we can properly control the type I error due to small sample size. However, SKAT-O also has its limitation: in the scenario that there are more neutral variants than actual deleterious variants, it may be slightly less powerful[31].

Our study suggests that variants in the COL6A3 gene may increase susceptibility to PD. Further studies on the function and mechanism of COL6A3 and other dystonia-related genes are needed to unravel the complexity of the association between PD and dystonia.

The limitations of our study are the small sample sizes and lack of function research. Currently, there are few studies of the relationship between COL6A3 and PD. Further clinical studies with a larger sample size more and diverse demographic background are warranted, along with basic studies exploring the biological function of COL6A3 and its associated pathways.

Declarations

Ethics approval and consent to participate

The study was approved by the Medical Ethics Committee of the Second Affiliated Hospital of Zhejiang University School of Medicine. All subjects completed informed consent for participation and publication of potential identifying information or images in an online open-access publication before the evaluation and original sample collection. All methods were carried out in accordance with relevant guidelines and regulations.

Competing interests

The authors disclose no conflicts of interest regarding this manuscript.

Funding sources

This work was supported by the National Natural Science Foundation of China [grant numbers 81520108010 and 81771216], the Key Research and Development Program of Zhejiang Province [grant number 2020C03020] and the Natural Science Foundation of Zhejiang Provincial [No. LY18H090003].

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors’ contributions

CYJ and JLP conceived the idea and drafted the manuscript.

CYJ, RZ ZHL, NJX, JT, XZY contributed to the collection and interpretation of the data.

YC, TG, YQY, YF, YPY helped in designing the study and collecting data.

Manuscript revisions were completed by both JLP and BRZ.

All authors read and approved the final manuscript.
Acknowledgements

Not applicable

Consent for publication

Signed consent for this publication has been obtained from all participating subjects.
