**Abstract:** A series of dinuclear copper(I) N,C,N- and P,C,P-carbodiphosphorane (CDP) complexes using multidentate ligands CDP(Py): (1) and (CDP(CH2PPh2): (13) have been isolated and characterized. Detailed structural information was gained by single crystal XRD analyses of nine representative examples. The common structural motive is the central double ylidic carbon atom with its characteristic two lone-pairs involved into binding of two geminal L-Cu(I) fragments at Cu-Cu distances in the range 2.55 – 2.67 Å. In order to enhance conformational rigidity within the characteristic Cu-Cu triangle, two types of chelating side arms were symmetrically attached to each phosphorus atom: two 2-pyridyl functions in ligand CDP(Py): (1) and its dinuclear copper complexes 2-9 and 11, as well as two diphenylphosphinomethylene functions in ligand CDP(CH2PPh2): (13) and its di- and mononuclear complexes 14-18. Neutral complexes were typically obtained via reaction of 1 with Cu(I) species CuCl, Cu, and CuSPh or via salt elimination reaction of [(CuCl)(CDP(Py))]: (2) with sodium carbazolate. Cationic Cu(I) complexes were prepared upon treating 1 with two equivalents of [Cu(NCMe)]:PF6, followed by the addition of either two equivalent of an aryl phosphine (PPh3, P(C6H4OMe)): or one equivalent of a biphosphine ligands DPEPhos, XantPhos or dpf. For the first time carbodiphosphorane CDP(CH2PPh2): (13) could be isolated upon treating its precursor [CH(dpmm)]:Cl (12) with NaNH: in liquid NH3. A protonated and a deprotonated derivative of ligand 13 were prepared and their coordination was compared to neutral CDP ligand 13. NMR analysis and DFT calculations reveal, that the most stable tautomer of 13 does not show a CDP (or carbone) structure in its uncoordinated base form. For most of the prepared complexes, photoluminescence upon irradiation with UV light at room temperature was observed. Quantum yields (ΦPL) were determined to 36% for dicationic [(CuPPh3)(CDP(Py))]:PF6: (4) and to 60% for neutral [(CuSPh3)(CDP(CH2PPh2))]: (16).

1. **Introduction**

In 1961, hexaphenyl-carbodiphosphorane, the first carbodiphosphorane (CDP), was synthesized by Ramirez et al. [1]. Regardless to this early discovery the interest in such double ylide carbon (or carbone) compounds is still evolving. One reason for attracting interest is the bonding description of carbodiphosphoranes. Next to a classical ylide valence bond description, the bonding in carbodiphosphoranes can be decribed as a formal carbon(0) atom stabilized by two dative phosphine ligands with C-P retro dative bonding components, a model discussed earlier but quantified by a theoretical approach of Frenking and co-workers [2–6]. The central carbon atom is best described in its excited singlet (1D) state [7]. It acts as an acceptor and is stabilized by the σ donating phosphine ligands. The two characteristic occupied lone pairs (HOMO and HOMO+1) centered at this carbon atom (therefore named “carbone”), are either capable to bind two metals via two σ bonds in a close
to tetrahedral configuration P:CM; or one metal in a trigonal-planar P:CM configuration via a σ- and a π dative bond of very strong π,σ-donor character [8]. For this reason, coordination chemistry of carbodiophosphoranes has experienced a renaissance [9–11]. A topic of current interest is introducing secondary ligand functions into the CDP frame: Cyclometalation with noble metals rhodium and platinum gave rise to the characterization of C,C,C-pincer ligand complexes with two cyclometalated phenyl rings [12–17], and ortho-directed double lithiation of hexaphenyl-carbodiophosphorane leads to lithium complexes capable to transfer the C,C,C-pincer ligand synthon [CDP]⁻ to any other element of the periodic table [17]. P,C,P-chelate complexes of a phosphine functionalized CDP ligand CDP(CH₂PPh₂): (13), formally a carbene C(dppm): (dppm = bis-diphenylphosphinomethane), were characterized, but the free ligand 13 was not isolated so far [18–24]. Only recently, complexes of 2-pyridyl functionalized N,C,N-carbodiophosphorane CDP(Py): (1) were reported [25,26]. The isolation of the free ligand base 1 [25] enabled the synthesis of Cu(I) CPD complexes, which are discussed in this work. Cu(I) complexes [27–43] can be used as cost efficient luminescent materials, which potentially can replace highly phosphorescent Ir [44–50] or Pt [47,51–58] complexes in OLED technology. For example, OLED devices with internal quantum efficiencies of up to 100% could be realized based on the TADF singlet harvesting mechanism [28–31,41]. According to this mechanism, both the singlet and triplet excitons formed in an OLED emission layer can be harvested and emission occurs via the S1 state.

Very frequently, Cu(I) complexes exhibit low-lying metal-to-ligand charge transfer (MLCT) transitions that are related to small energy separations ΔE(S1 – T1) between the lowest singlet S1 and the lowest triplet T1 state due to small HOMO-LUMO overlap. As a consequence, efficient up-intersystem crossing (T1→S1), also designated as reverse intersystem crossing RISC, can occur at near ambient temperature [28,41,45,59,60] thus, resulting in thermally activated delayed fluorescence (TADF). This is also related to a small transition dipole moment and, thus, a small radiative rate k(S→S0) [31,32]. The described CT transfer formally corresponds to oxidation of Cu(I) to Cu(II) and leads to a photo-induced structural rearrangements in the excited state(s) being connected to large Franck-Condon factors [61], and, as a consequence, to competing non-radiative relaxations. Therefore, the design of rigid structures with small reorganisation energy between ground state and excited states is essential.

While the first luminescent behaviour of a Au(I) N-heterocyclic carbene (NHC) complex was already described in 1999 [62], it took another ten years till the first photoluminescent Cu(I) NHC complexes were characterized [63] followed by further studies more recently [64–70]. In contrast to the π-acidic NHCs ligands, the π-donating CDP ligands have not yet been considered in luminescent materials. Herein, we report such luminescent Cu(I) CDP complexes, their synthesis, x-ray structure data, and PL properties. We demonstrate, that high emission quantum yields can be obtained with selected materials of this class.

2. Results

2.1 Synthesis and characterisation of N,C,N-CDP complexes

The N,C,N-carbodiophosphorine pincer ligand CDP(Py): (1) was synthesized as reported previously [23] and used as a ligand in order to synthesize neutral and cationic dinuclear copper(I) complexes. Complexes 2, 3 and 9 were conveniently prepared by stirring ligand 1 with two equivalents of the respective copper(I) salts CuX in THF at room temperature for 18 h. Moderate yields of 86% and 63% for 2 and 3, as well as 27% for 9 were achieved in form of orange powders. Dicationic complexes 4–9 were prepared in a in situ two-step protocol by reaction of CDP(Py): (1) with tetrakis(acetonitrile)copper(I) hexafluorophosphate (2 eq.) in THF, followed by addition of either two equivalents of monodentate triaryl phosphine or one equivalent of a bisphosphine ligand: Triphenylphosphine, tris(o-methoxyphenyl)phosphine, bis[2-diphenylphosphino)phenyl] ether (DPEPPhos), 4,5-bis(diphenylphosphino)-9,9-dimethylxanthene (XantPhos) and 1,1’-bis(diphenylphosphino) ferrocene (dpf) were chosen as ligands. The dicationic Cu(I) complexes were isolated and crystallized in yields of 47–90% (Scheme 1). Additionally, a neutral Cu(I) CDP complex was
obtained via deprotonation of carbazole (10) in THF using sodium tert-butoxide and addition of [(CuCl)(CDP(Py))]; (2) to this solution. [(CuCarb)(CDP(Py))]; (11) was obtained as light orange powder in a yield of 56%. Complexes 2-9 and 11 have been characterized via 31P NMR, 1H NMR, 13C NMR, and by elemental analyses. Due to the typically poor volatility of ionic and zwitterionic Cu(I) complexes 2-9 no mass spectra with molecular ions were obtained under EI, FD and ESI ionisation techniques. However, a molecular ion of 11 (m/z 539.18016: [M-H]+) could be detected by using liquid injection field desorption ionization (LIFDI) indicating the strong and proton capturing Cu-N bond between the copper(I) and the nitrogen atom of the N-carbazolyl anion. This strong interaction can be traced back to the C-N bond distance, which will be discussed below.

Scheme 1. Synthesis of a wide variety of novel dinuclear N,C,N-carbodiphosphorane complexes 2-9 and 11.

Single crystals suitable for X-ray diffraction analysis were obtained upon layering THF or DCM solutions of the complexes with n-pentane. Crystal structures for 2, 4, 6, 7, 9, and 11 are shown in Figure 1, selected bond distances and angles in Table 1. Further details of the XRD analyses of 3, 5 and 8 are described in the Supporting Information. The molecular structures of 2-9 reveal, that the central carbon atom within the CDP ligand is capable of coordinating two copper atoms in a geminal fashion. Each copper atom is additionally coordinated by one 2-pyridyl unit of ligand 1. If the Cu-Cu interaction is disregarded the two copper atoms per molecule are coordinated in a planar fashion, more T-shaped than trigonal planar. Each copper atom is interacting with one of the two carbene lone pairs of the central carbon atom C1, each by one nitrogen atom of a 2-pyridyl chelate ring and by the variable neutral ligand L or anionic ligand X. The strongest ligand interactions (C and X/phosphine) define a Cu(I) archetypical close to linear axis. The geminal nature of both copper(I) centers leads Cu-Cu distances in the range 2.55 – 2.67 Å (Table 1). These distances are smaller than twice the size of the covalent radius of Cu (1.32 Å) [71] or twice the size of the van der Waals radius of Cu (1.4 Å) [72]. Twice the size of the Cu(I) covalent radius (1.27 Å) [73] is close to the observed Cu-Cu distance. Similar trends are observed in dinuclear Cu(I) CDP complexes without any constraints of additional chelating CDP functions [74]. The Cu-Cu interaction leads to a formally coordinatively saturated pseudo tetrahedral coordination around each copper atom. This dinuclear entity is intramolecularly stabilized by a neutral 4-electron donor carbene ligand bridging the two Cu atoms. This rather rigid ligand template is characterized by characteristic torsion angles X-Cu-Cu-X in the range 41.9 ° (2) – 76.0 ° (3) for anionic ligands X (X = Cl, I, S(C6F5)) or L-Cu-Cu-L in the range 62.4 ° (8).
– 82.9 ° (4) for phosphine and the bridging bisphosphine ligands. The rather rigid frame of this N,C,N-ligand backbone seems to be privileged to stabilize this 8-electron-5-center inner Cu₂CN₂ core.

Figure 1. XRD molecular structures of [(CuCl₂(CDP(Py)₂)] (2), [Cu₂(PPh₃)(CDP(Py)₂)](PF₆)₂ (4), [Cu₂(DPEPhos)(CDP(Py)₂)](PF₆)₂ (6), [Cu₂(XantPhos) (CDP(Py)₂)](PF₆)₂ (7), [(CuS(C₆F₅))₂(CDP(Py)₂)] (9) and [(CuCarb)(CDP(Py)₂)] (11). Hydrogen atoms and solvent molecules have been omitted for clarity; thermal ellipsoids are given at 50% probability. For details and further XRD molecular structures of 3, 5 and 8 see the Supporting Information.

Representative parent complex 2 crystalizes in a triclinic crystal system with a crystallographic point group of P-1 and with four units and two unique molecules in the unit cell. One of the two independent molecules is slightly disordered, both have very similar geometric parameters. The angles (°) around copper are almost identical for the two Cu atoms, but crystallographically not strictly identical: C-Cu-Cl 162.11(8), C-Cu-N 89.45(9) and N-Cu-Cl 106.95(6). Each copper atom deviates only marginally from the plane defined by C, N and X = Cl to which copper(I) is bound. Cu-Cu distances, which indicate weak Cu-Cu interactions, e.g. 2.5325(5) Å for 2. The C-Cu-Cu angles of 2 and related species are typically sharp, e.g. 49.98(7) ° in case of 2. A comparable coordination scenario can be found for the other complexes 3-9. Only small differences for the C-P distances as well for the Cu-C-Cu and the P-C-C angles are observed within the series 2-9.
Complex 11 crystalizes in a monoclinic crystal system with a space group of $P2_1/n$ and four units in its unit cell. In contrast to the described XRD molecular structures of 2-9, the neutral complex 11 shows only one pyridine copper interaction, the remaining pyridyl unit stays in a dangling nonbonding situation. The carbazolyl anions display a perpendicular orientation with respect to each other. Both, steric and electronic factors are probably responsible for the dangling pyridyl unit in 11. As expected, the Cu-$N_{\text{an}}$ distance 1.911(3) Å for copper with the higher coordination number due to additional pyridine interaction is longer than Cu-$N_{\text{carb}}$ 1.861(2) Å for the other one. According to NMR spectroscopy, there is a dynamic exchange process of bonded and dangling pyridine ligands in solution.

### 2.2 Synthesis and characterisation of $P,C,P$-CDP complexes

Peringer et al. developed $P,C,P$-CDP pincer complexes of a formal carbene ligand C(dppm)$_2$, which was not isolated and characterized, but trapped in form of its complexes [18–24]. The synthetic strategy involved complex redox reactions. It is limited to the characterisation of Ni(II), Pd(II), Pt(II) or Au(III) complexes so far. Our synthetic approach was to isolate the free CDP base. Thus, [CH(dppm)$_2$]Cl (12) [18,19] was treated with an excess of sodium amide (6.5 eq.) in liquid ammonia at $-78 \, ^{\circ}$C. Since the basicity of sodium amide leads to deprotonation of only one proton, CDP(CH$_2$PPh)$_2$: (13) could be isolated in 98% yield as an intense yellow powder. No further deprotonation products and no adduct formation with lithium salts were observed as in case of using organolithium bases. The isolation of 13 was the precondition to access the coordination chemistry of Cu(I) with this $P,C,P$-CDP ligand base. Dinuclear copper complexes 14–16 where synthesized and characterized via NMR spectroscopy and mass spectrometry (Scheme 2). Upon treating 13 with tetrakis(acetonitrile)copper(I) hexafluorophosphate in DCM, a cationic complex [CuCl(H-CDP(CH$_2$PPh)$_2$)]PF$_6$ (17) was obtained. The enhanced basicity of alkyl-substituted CDP 13 compared to pyridyl-substituted CDP 1 leads to a protonation of a lewis acid activated acetonitrile ligand. Therefore, monoprotonated 13 is acting as ligand in mononuclear copper complex 17 with hexafluorophosphate as counter ion. While searching for adequate bases for the deprotonation of 12, we observed the ability of $n$-BuLi (2 eq.) to further deprotonate CDP 13, generating an anionic CDP ligand 20 (Scheme 3) as lithium salt. Trapping this anion with one equivalent of tetrakis(acetonitrile)copper(I) hexafluorophosphate and one equivalent of triphenylphosphine leads to neutral copper(I) complex 18 as a light yellow powder in 73% yield. 18 was characterized via $^{31}$P NMR, $^1$H NMR and elemental and XRD analysis.
Scheme 2. Synthesis of dinuclear $P,C,P$-CDP complexes 14-16 via isolation of previously non-characterized CDP(CH$_3$PPh)$_2$ (13). A mono-protonated form of 13 was trapped and characterized in 17 and a mono-deprotonated form of 13 in 18.

As $^{31}$P NMR spectra of symmetric 12 become complex upon formation of mono-deprotonated base 13, we anticipated the presence of tautomeric forms of 13. Potential tautomers were investigated via computational methods (Scheme 3). Geometry optimizations were performed at the PBE-D3(BJ)/def2-TZVPP level of theory. Followed by single point calculations and a natural bond orbital (NBO) analysis at the PBE0-D3(BJ)/def2-TZVPP level of theory. Interestingly, the results reveal that the free ligand base 13 cannot be acknowledged as a carbodiphosphorane, but rather as tautomer 13a. Due to the high first proton affinity (PA) and drastically lower second PA of the alkyl substituted central CDP carbon atom and due to the enhanced CH-acidity of the methylene group placed inbetween a phosphanyl and a phosphionio functionality, the ground state of 13 is not represented by tautomer 13c or 13b but by asymmetric tautomer 13a. This equilibrium explains the highly complex $^{31}$P NMR spectra obtained from solutions of pure 13. Symmetric tautomer 13b is 4.1 kcal/mol more stable than 13c, but asymmetric 13a is 7.7 kcal/mol more stable than 13b. Our results from solution and gas phase investigation and very clear results from XRD solid state investigations of ligand 13 complexes indicate, that the equilibrium of tautomers displayed in Scheme 3 is shifted towards 13c, if the free base 13 is trapped by coordination with two Cu(I) ions! Further deprotonation of 13a leads to symmetric carbanion 20 as most stable tautomer: 20a with equally CH-functionalized C1, C2 and C3 is 12.7 kcal/mole more stable than asymmetric tautomer 20b retaining a carbodiphosphorane structure. A hypothetical $^{13}C$, $^{3}C$, $^{3}C$ diphosphete derivate 20c is just 1.1 kcal/mole less stable than 20b in the gas phase. The charge distribution of the tautomers can be monitored via NBO analysis. While the atomic partial charge $q$(C) of C1 of 13a is −1.38 e, which corresponds to $q$(C) of the protonated hexaphenyl-carbodiphosphorane (−1.33 e) [6]; the one of 13c reveals as −1.45 e and therefore is in the same order of magnitude as for the hexaphenyl-carbodiphosphorane (−1.43 e) [6]. For 20a $q$(C) of C1, C2 and C3 are −1.39 e, 1.37 e and 1.37 e, while $q$(C) of P1, P2, P3 and P4 are 1.68 e, 1.68 e, 0.83 e and 0.83 e. For more information regarding the atomic partial charges and for a detailed deprotonation of 12 see Table S1-S8, as well as Scheme S-1 in the SI.
Scheme 3. Results of quantum chemical calculations on the deprotonation of \([H\text{-CDP(CH}_3\text{PPh}_2)_2]Cl\) (12) and formation of different more or less stable tautomers of \(\text{CDP(CH}_3\text{PPh}_2)_2\) (13). The positive value of the energy corresponds to the energy that has to be applied in order to convert one molecule into the other. The most stable tautomer 13a and its deprotonation product 20a are shown on the left side of the scheme.

Single crystals suitable for X-ray diffraction analysis where obtained upon layering a THF or a DCM solution of the complexes 14-18 with \(n\)-pentane. The XRD molecular structures are depicted in Figure 2, selected bond distances and angles in Table 2 and 3. For dinuclear complexes 14-16 a very similar trend is observed as discussed in chapter 2.1. The central CDP carbon atom acts as 4-electron donor involving two geminal copper atoms into a Cu-Cu triangle. Each copper atom is further coordinated to one chelating phosphine group. While 14 and 16 crystallize in a triclinic crystal system with space group \(P\)-1 and two units in the unit cell, 15 crystallizes in a monoclinic crystal system with space group \(C\)-2/c and four units in the unit cell. In contrast to dinuclear Cu(I) complexes of pyridyl-CDP 1, complexes 14-16 of phosphanyl-CDP 13 reveal significantly longer Cu-Cu distances (Å). 2.8681(5) (14), 2.8816(12) (15) and 2.989(2) (16) compared to 2.5525(5) (2) and 2.671(2) (11). This is in accord with the higher steric demand of the phosphine and an increased freedom of motion in CDP ligand 13 compared to the more rigid and compact CDP 1 (also compare the XYZ-file of the SI). In contrast to 2-9, disregarding the Cu-Cu interaction, a less pronounced T-shape but more trigonal planar coordination sphere of the copper(I) ions is observed for 14-16. This is probably due to the fact, that phosphines, carbones and the anions X are more similar in their donor strength and Cu(I) affinity compared to weaker pyridine ligands in the first series of compounds. For 14 the angles (°) around copper are 128.57(7) (C-Cu-Cl), 99.71(7) (C-Cu-P) and 129.61(3) (P-Cu-Cl) and therefore closer to the ideal 120° of a trigonal coordination sphere compared to 2. This rather rigid ligand template is characterized by characteristic torsion angles X-Cu-Cu-X in the range 119.9° (15) – 140.2 (16) and are therefore larger compared to the complexes of 2. The less rigid frame of this \(P,C,P\) ligand backbone stabilizes an 8-electron-5-center inner Cu:CP2 core.
Figure 2. XRD molecular structures of [(CuCl)$_2$(CDP(CH$_2$PPh$_2$)$_2$)] (14), [(CuI)$_2$(CDP(CH$_2$PPh$_2$)$_2$)] (15), [(CuSPh)$_2$(CDP(CH$_2$PPh$_2$)$_2$)] (16), [CuCl(H-CDP(CH$_2$PPh$_2$)$_2$)]PF$_6$ (17) and [CuPPh$_3$(CH(PPh$_2$CHPPh$_2$)$_2$)] (18). Hydrogen atoms and solvent molecules have been omitted for clarity; thermal ellipsoids are given at 50% probability. For more details see the Supporting Information.

Selected bond distances and angles of 14-16 can be found in Table 2, which demonstrates an increase of the Cu-Cu angle of about 10° in addition to the increased Cu-Cu distances relating to the increasing freedom of motion of 13 compared to 1. The P-C-P angles of the CDP complexes 14-16 are comparable to the ones of ligand 1.

Table 2. Selected bond distances [Å] and angles [°] for 14-16.

|        | 14   | 15   | 16   |
|--------|------|------|------|
| Cu-Cu  | 2.8681(5) | 2.8816(12) | 2.989(2) |
| C-P1   | 1.718(2)  | 1.716(3)  | 1.707(12) |

X=Cl, I or S.

Selected bond distances and angles of 17 and 18 are displayed in Table 3 and are compared to the ones of complex 14. While [CuCl(H-CDP(CH$_2$PPh$_2$)$_2$)]PF$_6$ (17) can be considered as a complex of a cationic ligand, [CuPPh$_3$(CH(PPh$_2$CHPPh$_2$)$_2$)] (18) has to be considered as an example of a complex with the deprotonated, anionic form of ligand 13. The charge distribution of the corresponding ligand is also reflected in the C-P distances within the complexes 14, 17 and 18. While C1-P1 and C1-P2 are distinctly shorter for 14 an increase in C-P bond distance is observed for 17 and 18 due to the protonation of C1. Furthermore, deprotonation of C2 and C3 of complex 18 leads to a shortening of the distances C2-P1, C2-P3 and C3-P2, C3-P4 compared to 14 and 17, where C2 and C3 are considered
as methylene groups. This also corresponds to the P1-C2-P3 and P2-C3-P4 angles, which are significantly larger for the anionic ligand complex 18 compared to 14 and 17.

2.3 Photophysical characterisation of selected CDP complexes

Since photophysical properties of carbodiphosphorane Cu(I) complexes have not yet been considered, first investigations were performed in this report. The Cu(I) complexes 2-7,9 and 14-16 show photoluminescence upon irradiation with UV light at room temperature. As proof of concept, we investigated emission spectra and quantum yields of [(CuPPh$_3$)$_2$(CDP(Py)$_2$)](PF$_6$)$_2$ (4) and [(CuSPh)$_2$(CDP(CH$_2$PPh$_2$)$_2$)] (16). Figure 3 illustrates the normalized room-temperature emission spectra of these materials. Compound 4 shows an emission maximum at 541 nm, corresponding to green/yellow color, along with a quantum yield ($\Phi_{PL}$) of 36% for the powder sample. The emission maximum of [(CuSPh)$_2$(CDP(CH$_2$PPh$_2$)$_2$)] (16) (powder) is found at 510 nm (green color) showing $\Phi_{PL} = 60%$. The high quantum yields indicate relatively high rigidity of the complexes in powder form. Moreover, these materials are chemically robust: After exposing the complexes to air for two months, the compounds still show their characteristic photoluminescence upon irradiation with UV light at room temperature.
First insight in the electronic structure of the emitting compounds 4 and 16 is obtained from consideration of the HOMO and LUMO distributions. Figure 4 shows that the HOMO shows for both compounds significant participation of metal d character as well as a marginal contribution of the central carbon. The LUMO, on the other hand, is primarily localized at the pyridyl units of the ligand backbone as well as on the phenyl groups attached to P1 and P2 for 16. Considering HOMO→LUMO transitions, the excitations can be ascribed to metal-to-ligand charge transfer (MLCT) transitions. Accordingly, it is indicated that the energy separations $\Delta E(S_1 - T_1)$ between the lowest singlet $S_1$ and triplet $T_1$ states are small enough to allow for up-ISC at ambient temperature [28,31,32]. Therefore, we tentatively assign the emission observed as TADF emission. Details will be reported in a subsequent study.

For completeness, it is mentioned that also complexes 17 and 18 exhibit photoluminescence upon irradiation with UV light at room temperature. This was not the case for [{Cu(dppf)}2(CDP(Py))2](PF6)2 (8) and [{CuCarb}2(CDP(Py))2] (11). For 8, quenching of the ferrocenyl ligand could be responsible for the lack of photoluminescence. In case of 11, a reason could be the asymmetric coordination found in the crystal structure. The reduced rigidity could lead to larger geometry rearrangement after excitation and thus, to quenching.
Figure 4. Kohn-Sham orbitals of HOMO (a), LUMO (b) of [(CuPPh3)2(CDP(Py))](PF6)2 (4) and HOMO (c), LUMO (d) of [(CuSPh)2(CDP(CH3PPh3))](16) calculated for the optimized Scs state geometry (isovalue = 0.05). Calculations were performed at the PBE-D3(BJ)/def2-TZVPP level of theory. For more details of the MOs compare Figure S-42 and Figure S-43 in the supplement.

3. Conclusion.

We successfully isolated and characterized a series of dinuclear copper(I) complexes of two so far poorly investigated, multidentate pyridyl and phosphanyl functionalized N,C,N- and P,C,P-carbodiphosphorane ligands. A series of neutral complexes of CDP(Py)2:1 with anionic coligands X and a series of dicationic complexes with monodentate and bridging bidentate bisphosphine ligands DPEPhos, XantPhos, dppf were fully characterized including their XRD molecular structures. In order to prepare unprecedented dinuclear copper complexes with a previously discovered carbodiphosphorane ligand backbone, it was necessary to isolate the free ligand base CDP(CH2PPh2)2 (13), which has not been demonstrated before. 13 can be obtained from [CH(dppm)2]Cl (12) and an excess of sodium amide in liquid ammonia. DFT calculations reveal, that the ground state of 13 has no CDP structure in the gas phase, but rather an unsymmetric tautomer form 13a. However, upon reaction with CuX, the CDP tautomer is trapped from the tautomeric equilibrium and neutral dinuclear Cu(I) CDP complexes are isolated and fully characterized. In addition, a protonated and a deprotonated ligand form of 13 were characterized in mononuclear complexes [CuCl(H-CDP(CH2PPh2)]PF6 (17) and [CuPPPhs(CH(PPh3)CHPPh3)] (18). With exception of [[Cu2(dppf)](CDP(Py))](PF6)2 (8) and [(CuCarb)(CDP(Py))] (11) the complexes studied show photoluminescence upon irradiation with UV light at room temperature. Photophysical measurements reveal quantum yields ΦPL of 36% and 60% for [(CuPPh3)2(CDP(Py))](PF6)2 (4) and [(CuSPh)2(CDP(CH3PPh2))] (16). As found in the crystal structure, the formal central carbon(0) atom is capable of coordinating two copper atoms relatively close two each other. They are further coordinated in a chelating manner to the chelating side arms of the CPDs. This rigid ligand design leads to high emission quantum yields and makes the CDP complexes relatively stable under air. Therefore, it is proposed to test the compound’s OLED suitability.

Supplementary Materials: The following are available online at www.mdpi.com/xxx/s1, Experimental section, NMR spectra, IR spectra, crystal data tables of 2 (2017394), 3 (2017392), 4 (2017399), 5 (2017397), 6 (2017398), 7 (2017400), 8 (2017406), 9 (2017395), 11 (2017393), 14 (2017408), 15 (2017410), 16 (2017409), 17 (2017407) and 18 (2017411) and DFT calculations (PDF).
