UPSILON INVARIANTS FROM CYCLIC BRANCHED COVERS

ANTONIO ALFIERI, DANIELE CELORIA, AND ANDRÁS STIPSICZ

Abstract. We extend the construction of $\Upsilon$-type invariants to null-homologous knots in rational homology three-spheres. By considering $m$-fold cyclic branched covers with $m$ a prime power, this extension provides new knot concordance invariants $\Upsilon_C^\ell(K)$. We give computations of these invariants for some families of alternating knots and reprove some independence results.

1. Introduction

Knot Floer homology turned out to be an extremely powerful tool in studying properties of knots. For $K \subset S^3$ the theory provides invariants which determine the Seifert genus of the knot [27], whether it is fibered or not [8, 24] (both achieved by the $\hat{HFK}$-theory), and further versions of the construction give lower bounds on the slice genus (the $\tau$ invariant stemming from the $HFK^-$-theory). The most general version (the bi-filtered, graded $\mathbb{Z}_2[U,U^{-1}]$-module $C\mathcal{F}\mathcal{K}_K^\infty$) gave rise to additional invariants, like Hom’s $\epsilon$-invariant [15], or the $\Upsilon$-function of [23], or its further variants $\Upsilon^C$ from [3].

More recently, based on work of Hendricks and Manolescu [13] involutive invariants emerged as useful tools in the theory. Most of these constructions worked for knots in $S^3$ and provided strong results on the structure of the smooth concordance group $C$.

In [25] Ozsváth, Szabó and the third author pointed out the possibility of capturing more information about concordance of knots in $S^3$ by running the routine of the upsilon invariant on their preimages to branched covers. In this paper we pursue that idea and perform some computations of the resulting invariants. Notice that this option was already explored by Grigsby, Ruberman, and Strle [11] in the case of the Ozsváth-Szabó $\tau$ invariant.

In the first part of the paper we extend the theory of upsilon type invariants to null-homologous knots in rational homology spheres (compare with [17]) and we apply it to branched covers to obtain invariants of knots in $S^3$. For a knot $K \subset S^3$, a cohomology class $\xi \in H^2(\Sigma_m(K);\mathbb{Z})$, where $\Sigma_m(K)$ denotes the $m$-fold branched cover along $K$ for some prime power $m$, and a south-west region of the plane $C$, we get a knot invariant $\Upsilon_C^\ell(K)$ with the following key property.

**Theorem 1.1.** If $K$ is a slice knot then there exists a subgroup $G < H^2(\Sigma_m(K);\mathbb{Z})$ of cardinality $\sqrt{|H^2(\Sigma_m(K);\mathbb{Z})|}$ such that $\Upsilon_C^\ell(K) = 0$ for all $\xi \in G$.

The second part of the paper is devoted to computations. We extend Grigsby’s result [9] Thm. 4.3 to encompass all spin$^c$ structures, in the subcase of alternating torus knots.

**Theorem 1.2.** Let $p = 2n + 1$ be a given positive odd integer. For $h \in \{0,\ldots,n\}$ there exist bi-graded quasi-isomorphisms

$$C\mathcal{F}\mathcal{K}_K^\infty(L(p,1),\tilde{T}_2,p, s_0 \pm h) \simeq C\mathcal{F}\mathcal{K}_K^\infty(T_{2,p-2h}).$$

This result determines $H\mathcal{F}\mathcal{K}_K^\infty(L(p,1),\tilde{T}_2,p)$ as a graded group, and implies that the lift of an alternating torus knot is thin in each spin$^c$ structure (cf. Section 6 of [18]).
Corollary 1.3. For an alternating torus knot $K = T_{2,2n+1}$ we have
\[ \Upsilon_{K,s_0+h}(t) = (1-t)(t-1) \quad -n \leq h \leq n. \]

Theorem 1.2 can also be applied to compute the $\tau$-invariants studied in [31].

Corollary 1.4. For $h = 0, \ldots, n$ one has
\[ \tau_{s_0+h}(T_{2,2n+1-2h}) = -\frac{1}{2} \sigma(T_{2,2n+1-2h}) = n - h, \]

Corollary 1.5. Consider a knot $K \subset S^3$. Suppose $K \sim T_{2,2n+1}$ for some $n > 0$, then
\[ \det(K) > \frac{2n+1}{4}. \]

We then work out complete calculations in the case of twist knots. Indeed, our strategy applies more in general to $(1,1)$-knots. Further computations are going to appear in [11], using lattice cohomology techniques.

2. AN INVARIANCE PRINCIPLE

An Alexander filtered, Maslov graded chain complex is a finitely-generated, $\mathbb{Z}$-graded, $(\mathbb{Z} \oplus \mathbb{Z})$-filtered chain complex $\mathcal{K}_* = (\bigoplus_{x \in B} \mathbb{Z}_2[U,U^{-1}], \partial)$ satisfying the following properties

- $\partial$ is $\mathbb{Z}_2[U,U^{-1}]$-linear, and given a basis element $x \in B$, $\partial x = \sum_y n_{x,y} U^{m_{x,y}} - y$ for suitable coefficients $n_{x,y} \in \mathbb{Z}_2$, and non-negative exponents $m_{x,y} \geq 0$,
- the multiplication by $U$ drops the homological (Maslov) grading $M$ by two, and the filtration levels (denoted by $A$ and $j$) by one.

An Alexander filtered, Maslov graded chain complex is said to be of knot type if in addition $H_0(\mathcal{K}_*, \partial) = \mathbb{Z}_2[U,U^{-1}]$ graded so that $\text{gr}(1) = d(\mathcal{K}_*)$, for some $d(\mathcal{K}_*) \in \mathbb{Q}$. The number $d(\mathcal{K}_*)$ is a characteristic quantity of $\mathcal{K}_*$: the correction term of $\mathcal{K}_*$. An Alexander filtered, Maslov graded chain complex $\mathcal{K}_*$ can be pictorially described as follows:

- picture each $\mathbb{Z}_2$-generator $U^m \cdot x$ of $\mathcal{K}_*$ as a point on the planar lattice $\mathbb{Z} \times \mathbb{Z} \subset \mathbb{R}^2$ in position $(A(x) - m, -m) \in \mathbb{Z} \times \mathbb{Z}$,
- label each $\mathbb{Z}_2$-generator $U^m \cdot x$ of $\mathcal{K}_*$ with its Maslov grading $M(x) - 2m \in \mathbb{Z}$,
- connect two $\mathbb{Z}_2$-generators $U^m \cdot x$ and $U^n \cdot y$ with a directed arrow if in the differential of $U^n \cdot x$ the coefficient of $U^m \cdot y$ is non-zero.

We will consider knot type complexes up to stable equivalence rather than up to filtered chain homotopy.

Two knot type complexes $\mathcal{K}_1$ and $\mathcal{K}_2$ are said to be stably equivalent, denoted by $\mathcal{K}_1 \sim \mathcal{K}_2$, if there exist two Alexander filtered, Maslov graded, acyclic chain complexes
\( \mathcal{A}_1 \) and \( \mathcal{A}_2 \) such that \( \mathcal{K}_1 \oplus \mathcal{A}_1 \simeq \mathcal{K}_2 \oplus \mathcal{A}_2 \), where \( \simeq \) denotes chain homotopy equivalence. Denote by \( \mathcal{CF}_K \) the set of knot type complexes up to chain homotopy equivalence. The quotient set \( \mathcal{CF}_K/\sim \) has a natural group structure, with operation given by tensor product, and identity represented by the chain complex \( \mathbb{Z}_2[U,U^{-1}] \), equipped with \( \partial = 0 \) and the trivial filtration; the inverse of the class of a complex \( \mathcal{K}_* \) is represented by its dual complex \( \text{Hom}(\mathcal{K}_*, \mathbb{Z}_2[U,U^{-1}]) \). Let \( \mathcal{GCF}_K \) denote this Abelian group.

Let \( K \) be a null-homologous oriented knot in a rational homology sphere \( (\mathbb{Q} HS^3) Y \). Knot Floer homology \([28]\) associates to the pair \( (Y, K) \) a finitely generated, \( \mathbb{Z} \)-graded, \( (\mathbb{Z} \oplus \mathbb{Z}) \)-filtered chain complex

\[
\mathcal{CF}_K^\infty(Y, K) = \left( \bigoplus_{x \in B} \mathbb{Z}_2[U,U^{-1}] \cdot x, \partial \right)
\]

which is an Alexander filtered, Maslov graded chain complex in the above sense.

For each basis element \( x \in B \), there is an associated spin\(^c\) structure \( s(x) \in \text{Spin}^c(Y) \), and for each spin\(^c\) structure \( s \) of \( Y \)

\[
\mathcal{CF}_K^\infty(Y, K, s) = \bigoplus_{s(x) = s} \mathbb{Z}_2[U,U^{-1}] \cdot x
\]

is a subcomplex of the knot Floer complex \( \mathcal{CF}_K^\infty(Y, K) \), and

\[
\mathcal{CF}_K^\infty(Y, K) = \bigoplus_{s \in \text{Spin}^c(Y)} \mathcal{CF}_K^\infty(Y, K, s).
\]

The chain complex \( \mathcal{CF}_K^\infty(Y, K, s) \) satisfies

\[
H_*:\left(\mathcal{CF}_K^\infty(Y, K, s)\right) = HF^\infty(Y, s) = \mathbb{Z}_2[U,U^{-1}]
\]

graded so that \( \text{gr}(1) = d \), where \( d = d(Y, s) \) denotes the correction term of \( (Y, s) \) as defined in \([29]\). In conclusion, \( \mathcal{CF}_K^\infty(Y, K, s) \) is a chain complex of knot type.

In \([28]\) Ozsváth and Szabó proved that the \( \mathbb{Z} \)-graded, \( (\mathbb{Z} \oplus \mathbb{Z}) \)-filtered chain homotopy type of \( \mathcal{CF}_K^\infty(Y, K, s) \) only depends on the diffeomorphism type of the pair \( (Y, K) \), and on the chosen spin\(^c\) structure \( s \). Moreover, the homology of the graded object associated to \( \mathcal{CF}_K^\infty(Y, K, s) \) is of rank 1 over \( \mathbb{Z}_2[U,U^{-1}] \); this is the second page in a spectral sequence abutting to the Heegaard Floer homology \( HF^\infty(Y, s) \) of the ambient 3-manifold. If \( (Y, s) \) is a spin\(^c\) \( \mathbb{Q} HS^3 \), then \( HF^\infty(Y, s) = \mathbb{Z}_2[U]_{(d)} \oplus HF_{\text{red}}(Y, s) \), where again \( \mathbb{Z}_2[U]_{(d)} \) is graded so that 1 is in degree \( d(Y, s) \); this is commonly referred to as a tower. The second summand \( HF_{\text{red}}(Y, s) \) is a finitely generated \( \mathbb{Z}_2 \)-module.

A coarser equivalence relation among the pairs \( (Y, K) \), generalizing usual knot concordance, is defined as follows.

**Definition 2.1.** For \( i = 0, 1 \) let \( Y_i \) be a rational homology sphere, \( K_i \subset Y_i \) a null-homologous knot, and \( s_i \in \text{Spin}^c(Y_i) \). We will say that \( K_0 \) and \( K_1 \) are \textbf{spin\(^c\) rationally concordant}, if there exists a smooth spin\(^c\) rational homology cobordism \( (W, t) \) from \( (Y_0, s_0) \) to \( (Y_1, s_1) \), and a smoothly properly embedded cylinder \( C \subset W \) such that \( \partial C = C \cap \partial W = K_1 \cup -K_0 \).

A null-homologous knot \( K \) in a spin\(^c\) rational homology sphere \( (Y, s) \) is \textbf{rationally slice} if there exists a spin\(^c\) rational homology ball \( (W, t) \) bounding \( (Y, s) \) containing a smoothly properly embedded disk \( \Delta \subset W \) such that \( \partial \Delta = \Delta \cap \partial W = K \).

Let \( C_\mathbb{Q} \) denote the set of triples \( (Y, K, s) \), where \( Y \) is a rational homology sphere, \( K \subset Y \) a null-homologous knot, and \( s \in \text{Spin}^c(Y) \), considered up to rational concordance.
\( C_Q \) has a group structure induced by connected sum
\[
(Y_0, K_0, s_0)\#(Y_0, K_0, s_1) = (Y_0\#Y_1, K_0\#K_1, s_0\#s_1).
\]

In this group structure rationally slice knots represent the class zero, and the inverse corresponds to taking the mirror image \(-(Y, K, s) = (-Y, -K, \bar{s})\). Here \(-K\) denotes the knot \(K\) endowed with its opposite orientation, and \(\bar{s}\) denotes the conjugate of \(s\).

The main goal of this section is to prove the following theorem, generalizing to rational homology spheres a result of Hom [16, Theorem 1], cf. also [17, Section 4].

**Theorem 2.2.** Let \((Y_0, K_0, s_0)\) and \((Y_1, K_1, s_1)\) be two spin\(^c\) rationally concordant knots. Then the chain complexes \(\CFK^\infty(Y_0, K_0, s_0)\) and \(\CFK^\infty(Y_1, K_1, s_1)\) are stably equivalent, that is, there exist \(\mathbb{Z}\)-graded, \((\mathbb{Z} \oplus \mathbb{Z})\)-filtered, acyclic chain complexes \(A_0\) and \(A_1\) (that is, \(H_*(A_i) = 0\)) such that
\[
\CFK^\infty(Y_0, K_0, s_0) \oplus A_0 \simeq \CFK^\infty(Y_1, K_1, s_1) \oplus A_1,
\]
where \(\simeq\) denotes graded bi-filtered chain homotopy equivalence.

Theorem 2.2 can be deduced from the following lemma.

**Lemma 2.3.** Let \(K\) be a null-homologous knot in a rational homology sphere \(Y\), and \(s \in \text{Spin}^c(Y)\). If \(K\) is rationally slice, then there exists a \(\mathbb{Z}\)-graded, \((\mathbb{Z} \oplus \mathbb{Z})\)-filtered, acyclic chain complex \(A\) such that
\[
\CFK^\infty(Y, K, s) \simeq \CFK^\infty(S^3, U, u) \oplus A,
\]
where \(U \subset S^3\) denotes the unknot, and \(u\) denotes the only spin\(^c\) structure of \(S^3\).

**Remark 2.1.** It is not hard to see that \(\CFK^\infty(S^3, U, u) \simeq \mathbb{Z}_2[U, U^{-1}]\) with \(\partial = 0\), \(gr(1) = 0\), and both the Alexander and algebraic filtration level of 1 is zero.

**Proof of Theorem 2.2.** Note that

- if \((Y_0, K_0, s_0)\) and \((Y_1, K_1, s_1)\) represent rationally concordant null-homologous knots then \((Y_1\# - Y_0, K_1\# - K_0, s_1\#\bar{s}_0)\) is rationally slice,
- according to [28] for \((Y_0, K_0, s_0)\), \((Y_1, K_1, s_1)\) null-homologous knots we have
\[
\CFK^\infty(Y_0\#Y_1, K_0\#K_1, s_0\#s_1) \simeq \CFK^\infty(Y_0, K_0, s_0) \otimes \mathbb{Z}_2[U, U^{-1}] \CFK^\infty(Y_1, K_1, s_1).
\]

For \(i = 0, 1\) let \(Y_i\) be a rational homology sphere, \(K_i \subset Y_i\) a null-homologous knot, and \(s_i \in \text{Spin}^c(Y_i)\). Suppose that \(K_0\) and \(K_1\) are rationally concordant, and consider the chain complex
\[
K_* = \CFK^\infty(Y_0\#(-Y_1)\#Y_1, K_0\#(-K_1)\#K_1, s_0\#\bar{s}_1\#s_1),
\]
where \(-Y_1\) stands for the three-manifold \(Y_1\) with its reversed orientation, and \(-K_1\) is the knot \(K_1\) with its orientation reversed. As consequence of Lemma 2.3 we have that
\[
K_* \simeq \CFK^\infty(Y_0, K_0, s_0) \otimes \CFK^\infty((-Y_1)\#Y_1, (-K_1)\#K_1, s_0\#\bar{s}_1\#s_1)
\]
\[
\simeq \CFK^\infty(Y_0, K_0, s_0) \otimes (\CFK^\infty(S^3, U, u) \oplus A_*),
\]
\[
\simeq (\CFK^\infty(Y_0, K_0, s_0) \otimes \CFK^\infty(S^3, U, u)) \oplus (\CFK^\infty(Y_0, K_0, s_0) \otimes A_*),
\]
\[
\simeq \CFK^\infty(Y_0\#S^3, K\#U, s_0\#u) \oplus (\CFK^\infty(Y_0, K_0, s_0) \otimes A_*),
\]
\[
= \CFK^\infty(Y_0, K_0, s_0) \oplus (\CFK^\infty(Y_0, K_0, s_0) \otimes A_*),
\]
By considering the degree-shift formula \([26]\), we obtain

\[
\text{level spanned by generators with Alexander filtration level } A
\]

Let

\[
\text{for some acyclic complex } A
\]

again for some acyclic complex \(A\). Thus

\[
\text{CFK}^\infty(Y_0, K_0, s_0) \oplus A_0 \simeq \text{CFK}^\infty(Y_1, K_1, s_1) \oplus A_1
\]

where \(A_0 = \text{CFK}^\infty(Y_0, K_0, s_0) \otimes A\) and \(A_1 = B_\ast \otimes \text{CFK}^\infty(Y_1, K_1, s_1)\). Using the Künneth formula one conclude that \(A_0\) and \(A_1\) are both acyclic. \(\square\)

For the proof of Lemma \(2.3\) we need a little preparation. Let \(K \subseteq Y\) and \(s\) be as above, and consider the knot Floer complex \(\text{CFK}^\infty(Y, K, s)\). For \(m \geq 0\) set

\[
V_K(m, s) = d(Y, s) - 2 \cdot \min \max_i (A(z_i) - m, j(z_i))
\]

where \(z_1, \ldots, z_k \in \text{CFK}^\infty(Y, K, s)\) are the cycles with Maslov grading \(d = d(Y, s)\) representing the non-zero element of \(H_d(\text{CFK}^\infty(Y, K, s)) = \mathbb{Z}_2\). Our first goal is to relate \(V_K(m, s)\) to the correction terms of the surgeries along \(K\).

Given a null-homologous knot \(K \subset Y\), define its \textit{four-dimensional genus} \(g_s(K)\) as the minimal genus of a smooth, compact surface in \(Y \times [0, 1]\) with boundary \(K \times \{0\}\).

**Proposition 2.4.** Let \(K \subseteq Y\) be a null-homologous knot in a rational homology sphere \(Y\), and \(s \in \text{Spin}^c(Y)\). Pick an integer \(q \geq 2g_s(K) - 1\). Denote by \(W_q(K)\) the \(q\)-framed two-handle attachment along \(K \times \{1\} \subset Y \times [0, 1]\), so that \(\partial W_q(K) = Y_q(K) \cup -Y\).

For any integer \(m \in [-q/2, q/2]\), let \(s_m \in \text{Spin}^c(Y_q(K))\) denote the restriction of a \(\text{spin}^c\) structure \(t_m\) on \(W_q(K)\) extending \(s\) to \(Y_q(K)\), and satisfying \(\langle c_1(t_m), [\hat{F}] \rangle + q = 2m\), where \(\hat{F} \subset W_q(K)\) denotes a Seifert surface \(F\) for \(K\), capped-off with the core of the \(2\)-handle. Then

\[
d(Y_q(K), s_m) = \frac{(q - 2m)^2 - q}{4q} + V_K(m, s)
\]

**Proof.** Let \(\text{CFK}^\infty(Y, K, s)\{A \leq m, j \leq 0\}\) denote the subcomplex of \(\text{CFK}^\infty(Y, K)\) spanned by generators with Alexander filtration level \(A \leq m\), and algebraic filtration level \(j \leq 0\). According to [28, Section 4] we have that:

- \(\text{CFK}^\infty(Y, K, s)\{A \leq m, j \leq 0\}\) is chain homotopy equivalent to \(\text{CF}^-(Y_q(K), s_m)\);
- \(\text{CFK}^\infty(Y, K, s)\{j \leq 0\}\), the subcomplex of \(\text{CFK}^\infty(Y, K)\) spanned by the generators with algebraic filtration level \(j \leq 0\), is chain homotopy equivalent to the Heegaard Floer complex of the ambient 3-manifold \(\text{CF}^-(Y, s)\);
- the inclusion \(\text{CFK}^\infty(Y, K, s)\{A \leq m, j \leq 0\} \hookrightarrow \text{CFK}^\infty(Y, K, s)\{j \leq 0\}\) descends in homology to the map \(F_{X,t_m} : HF^-(Y_q(K), s_m) \to HF^-(Y, s)\) induced by the cobordism \(X = -W_q(K)\).

By considering the degree-shift formula [28], we obtain

\[
\text{gr}(F_{X,t_m}(\xi)) - \text{gr}(\xi) = \frac{c_1(s_m)^2 - 2\chi(X) - 3\sigma(X)}{4},
\]
where $\xi$ denotes the generator of the free summand of $HF^-(Y_q(K), s_m)$. Thus
\[
d(Y_q(K), s_m) = d + \frac{(q - 2m)^2 - q}{4q},
\]
where $d$ is the grading of the generator of the free summand of $H_\ast(CFK^\infty(Y, K, s) \{ A \leq m, j \leq 0 \})$. Since the inclusion
\[
CFK^\infty(Y, K, s) \{ A \leq m, j \leq 0 \} \hookrightarrow CFK^\infty(Y, K, s) \{ j \leq 0 \}
\]
maps the generator of the free summand of $HF^-(Y_q(K), s_m)$ to a $\mathbb{U}^n$-multiple of the one of $HF^-(Y, s)$, if $z_1, \ldots, z_k \in CFK^\infty(Y, K, s)$ denote the cycles with Maslov grading $M = d(Y, s)$ representing 1, and $\mathbb{U}^n$ is a two-sphere with $\partial \mathbb{U} = 0$ let $\Delta_i$ be a $(q - 2m)$-framed 2-handle along $K_i$. The resulting cobordism $X$ from $Y_q(K_0)$ to $Y_q(K_1)$ with $H_\ast(X; \mathbb{Z}) = \mathbb{Z}/q\mathbb{Z}$. Since by construction $c_1(t')[S] = 0$, the spin$^c$ structure $t'|_{W' - \nu S}$ extends to a spin$^c$ structure $t_X$ of $X = (W' - \nu S) \cup \partial S^1 \times B^3$. Summarizing, the pair $(X, t_X)$ provides a spin$^c$ rational homology cobordism from $(Y_q(K_0), s_m)$ to $(Y_q(K_1), s_m)$. This implies that $d(Y_q(K_0), s_m) = d(Y_q(K_1), s_m)$, and the claim now follows from Proposition 2.4.

**Corollary 2.5.** Let $K \subset Y$ be a knot in a rational homology sphere, $s \in \text{Spin}^c(Y)$ and $m \in \mathbb{N}$. Then $V_K(m, s)$ is a spin$^c$ rational concordance invariant.

**Proof.** For $i = 0, 1$ let $(Y_i, s_i)$ be a spin$^c$ rational homology spheres, $K_i \subset Y_i$ null-homologous knots, such that $(Y_0, K_0, s_0)$ and $(Y_1, K_1, s_1)$ are rationally concordant knots. We want to prove that $V_{K_0}(m, s_0) = V_{K_1}(m, s_1)$.

Let $(W, C, t)$ be a spin$^c$ rational homology cobordism from $(Y_0, K_0, s_0)$ to $(Y_1, K_1, s_1)$. Pick a suitably large $q \geq 0$, glue to $W$ a $q$-framed 2-handle along $K_0 \subset -Y_0 \subset \partial W$ and a $(-q)$-framed 2-handle along $K_1 \subset Y_1 \subset \partial W$. Denote by $W'$ the resulting cobordism from $Y_q(K_0)$ to $Y_q(K_1)$. Note that $W'$ is naturally equipped with a spin$^c$ structure $t'$ agreeing with $t$ on $W \subset W'$, and restricts to the spin$^c$ structure $s_m$ of Proposition 2.4 on its two boundary components.

Clearly $W'$ is not a rational homology cobordism, as $H_2(W'; \mathbb{Z}) = \mathbb{Z}^2$ is generated by the homology classes of the two 2-handles we attached along $K_0$ and $K_1$. For $i = 0, 1$ let $\Delta_i \subset W'$ be the core disk of the 2-handle attached along $K_i$. Set $S = \Delta_0 \cup C \cup -\Delta_1$; then $S$ is a two-sphere with $S \cdot S = 0$. Surgering out $S$ we get a rational homology cobordism $X$ from $Y_q(K_0)$ to $Y_q(K_1)$ with $H_\ast(X; \mathbb{Z}) = \mathbb{Z}/q\mathbb{Z}$. Since by construction $c_1(t')[S] = 0$, the spin$^c$ structure $t'|_{W' - \nu S}$ extends to a spin$^c$ structure $t_X$ of $X = (W' - \nu S) \cup \partial S^1 \times B^3$. Summarizing, the pair $(X, t_X)$ provides a spin$^c$ rational homology cobordism from $(Y_q(K_0), s_m)$ to $(Y_q(K_1), s_m)$. This implies that $d(Y_q(K_0), s_m) = d(Y_q(K_1), s_m)$, and the claim now follows from Proposition 2.4.

**Corollary 2.6.** $V_K(m, s) \equiv 0$ for a rationally slice knot $(Y, K, s)$.

**Proof.** A rationally slice knot is rationally concordant to the unknot $(S^3, U)$. For the unknot one has
\[
CFK^\infty(S^3, U, u) = \mathbb{Z}_2[U, U^{-1}] \cdot z, \quad \partial z = 0
\]
graded so that $A(z) = j(z) = M(z) = 0$. Thus,
\[
V_U(m, u) = d(S^3, u) - 2\max(A(z) - m, j(z)) = -2\max(-m, 0) = 0,
\]
for every $m \geq 0$. \qed
**Proof of Lemma 2.7.** The proof is a simple adaptation of [16] Proposition 11. Our first task is to find a cycle \( \xi \) with bi-filtration level \((0, 0)\). If \((Y, K, s)\) is rationally slice then

\[
0 = V_K(0, s) = d(Y, s) - 2 \cdot \min_{\xi} \max(A(\xi), j(\xi)) = -2 \cdot \min_{\xi} \max(A(\xi), j(\xi))
\]

where the minimum is taken over all cycles \( \xi \in \CF(K, Y, K, s) \) having Maslov grading \( M(\xi) = d(Y, s) = 0 \). Here \( d(Y, s) = 0 \), since \((Y, s)\) bounds a spin\(^c\) rational homology disk. Thus, we can find a cycle \( \xi \) representing the generator of \( H_0(\CF(K, Y, K, s)) \) is non-zero we are done. To this end, note that the projection

\[
\pi : \CF^+(Y, s) = \CF(K, Y, K, s)_{j \geq 0} \to \CF(K, Y, K, s)_{j \geq 0}, A \geq 0
\]

is dual (cf. [28]) to the inclusion

\[
i : \CF(K, Y, K, s)_{j \leq 0}, A \leq 0 \to \CF^-(Y, s) = \CF(K, Y, K, s)_{j \leq 0}.
\]

Now, since \( i \) is surjective on the free summand (as a consequence of the fact that \( V_K(0, s) = 0 \)), \( \pi \) is injective on the tower, leading to the conclusion that \( \pi(\xi^+) \neq 0 \). This proves that the top component of \( \xi \) has bi-filtration level \((0, 0)\).

Choose a filtered basis \( \{\xi_0, \ldots, \xi_m\} \) of \( \CF(K, Y, K, s) \) in which \( \xi \) appears as the first basis element \( \xi_0 \). After possibly making a filtered change of basis, we can assume that \( \xi_0 \) does not appear in the differential of the other basis elements. The desired direct sum splitting is given by \( \CF(K, Y, K, s) = \mathbb{Z}_2[U, U^{-1}] \cdot \xi_0 \oplus \langle \xi_1, \ldots, \xi_m \rangle \mathbb{Z}_2[U, U^{-1}] \).

The above result can be summarized as follows:

**Lemma 2.7.** The map \( \CF(K) : C_Q \to C_{\CF(K)} \) defines a group homomorphism.

**Proof.** \( \CF(K) \) associates to a null-homologous knot \( K \) in a spin\(^c\) \( \mathbb{Q}HS^3 \) \((Y, s)\) a knot type complex \( \CF(K, Y, K, s) \) with \( d(\CF(K, Y, K, s)) = d(Y, s) \), well-defined up to \( (\mathbb{Z} \oplus \mathbb{Z}) \)-filtered chain homotopy equivalence. As a consequence of Theorem 2.2, the map \( \CF(K) \) descends to a map \( C_Q \to C_{\CF(K)} \). This is a group homomorphism in view of [28] Proposition 4.

We conclude this section by recalling yet another (but, as it turns out to be, equivalent) equivalence relation among chain complexes: local equivalence. Although stable equivalence turns out to be very convenient in defining invariants (as it will be clear from our later constructions), local equivalence is phrased more naturally, since it takes maps between the actual chain complexes into account, and these maps are naturally induced by cobordisms and concordances.

**Definition 2.8.** Suppose that \( K_i \) for \( i = 1, 2 \) are knot type chain complexes over \( \mathbb{Z}_2[U, U^{-1}] \); the we say that \( K_0 \) and \( K_1 \) are **locally equivalent** if there are graded, bi-filtered chain maps \( f : K_1 \to K_2 \) and \( g : K_2 \to K_1 \) inducing isomorphisms on the homologies.

**Theorem 2.9.** If the knots \((Y_1, K_1, s_1)\) and \((Y_2, K_2, s_2)\) are rationally concordant (in the sense of Definition 2.7) then the corresponding graded, bi-filtered chain complexes \( \CF(K_1, Y_1, K_1, s_1) \) are locally equivalent.
Proposition 3.1. Each of these families can be used to produce a one-parameter family of knot type complexes then $\Upsilon^C(K_\ast) = \Upsilon^C(K_\ast')$. Consequently, for every south-west region $C$ of the plane and a knot type complex $K_\ast$ set

$$\Upsilon^C(K_\ast) = \inf \{ t \mid K_\ast(C_t) \hookrightarrow K_\ast \text{ induces a surjective map on } H_{d(K_\ast)} \} ,$$

where $C_t = \{(x,y) \mid (x-t, y-t) \in C\}$ denotes the translate of $C$ with the vector $v_t = (t, t)$. Here we are using the Maslov grading as homological grading, so $H_q(K_\ast) = \mathbb{Z}_2$ for $q \in d(K_\ast) + 2\mathbb{Z}$, and zero otherwise. Since the elements with Maslov grading equal to $d(Y,s)$ form a finite dimensional subspace, it is easy to see that for $t \ll 0$ the map $K_\ast(C_t) \hookrightarrow K_\ast$ induces the zero-map on $H_{d(K_\ast)}$, while for $t \gg 0$ the induced map is surjective. The same finiteness also implies that the infimum appearing in the definition above is indeed a minimum, hence in what follows we will write $\min$ instead of $\inf$. The next result was pointed out in [3].

Proposition 3.1. Let $C$ be a south-west region. If $K_\ast$ and $K_\ast'$ are two stably equivalent knot type complexes then $\Upsilon^C(K_\ast) = \Upsilon^C(K_\ast')$. Consequently, for every south-west region $C$ we get a map $\Upsilon^C : \mathcal{GCFK}/\sim \to \mathbb{R}$. \hfill $\Box$

In Figure 1 some notable families of south-west regions are shown. Thanks to Proposition 3.1 each of these families can be used to produce a one-parameter family of stable equivalence invariants.

In what follows we will assume that the south-west region $C$ is normalized, that is it contains the origin $(0,0) \in \mathbb{R}^2$ on its boundary $\partial C$. This condition ensures that $\Upsilon^C(\mathcal{CFK}\infty(S^3, U, u)) = 0$.

3.1. Some concordance invariants of classical knots. We can now use the results of the previous sections to define some concordance invariants of knots in $S^3$. Given $K \subset S^3$ we can form its $m$-fold cyclic branched cover $\Sigma^m(K)$. This is a 3-manifold equipped with an order $m$ self-diffeomorphism $\tau$.

The fixed locus of the $\mathbb{Z}/m\mathbb{Z}$-action defined by $\tau$ describes a knot $\widetilde{K} \subset \Sigma^m(K)$. The following result is part of knot theory folklore (see e.g. [21] Section 3).

Lemma 3.2. If $m$ is a prime power, then $\Sigma^m(K)$ is a rational homology sphere.
Figure 1. Examples of normalized south-west domains.

Proof. \( \tilde{K} \subset \Sigma^m(K) \) is a null-homologous knot since it bounds any lift \( \tilde{F} \subset \Sigma^m(K) \) of a Seifert surface \( F \subset S^3 \) of \( K \). Using a Seifert matrix \( \theta_{\tilde{F}} \) of \( \tilde{F} \) one can define the Alexander polynomial of \( \tilde{K} \) via the formula \( \Delta_{\tilde{K}}(x) = \det(x\theta_{\tilde{F}} - x^{-1}\theta_{\tilde{F}}) \).

The first homology \( H_1(\Sigma^m(K); \mathbb{Z}) \) is of order \( |\Delta_{\tilde{K}}(-1)| \) if the latter is non-zero, and infinite otherwise. The Alexander polynomial of \( \tilde{K} \) can be computed from the usual Alexander polynomial of \( K \) by the formula

\[
\Delta_{\tilde{K}}(x) = \prod_{i=0}^{m-1} \Delta_K(\omega^i x^{1/m})
\]

where \( \omega \) denotes a primitive \( m \)th root of unity. When \( m = p^k \) is a power of a prime,

\[
|\Delta_{\tilde{K}}(-1)| = \prod_{i=0}^{m-1} |\Delta_K(\omega^i)| \neq 0,
\]

since the Alexander polynomial of a knot does not vanish at any \( p^k \) root of unity: if it did then it would be divisible by the cyclotomic polynomial \( \phi_{p^k}(x) = \sum_{i=0}^{p^k-1} x^i - 1 \) implying that \( \phi_{p^k}(1) = p \) divides \( \Delta_K(1) = 1 \), a contradiction. \( \square \)

Remark 3.1. The Alexander polynomial \( \Delta_{\tilde{K}}(x) \) admits a refinement according to spin\(^c\) structures, see [33].

The \( m \)-fold cyclic branched cover \( \Sigma^m(K) \) of a knot \( K \subset S^3 \) admits a preferential Spin structure \( s_0 \) that can be used to canonically identify \( \text{Spin}^c(\Sigma^m(K)) \) with its second cohomology group \( H^2(\Sigma^m(K); \mathbb{Z}) \approx H_1(\Sigma^m(K); \mathbb{Z}) \) (cf. [11] and [18]).

Lemma 3.3 (Lemma 2.1 [11]). Let \( \Sigma^m(F) \) denote the \( m \)-fold cyclic branched cover of a properly embedded surface \( F \subset B^4 \), with boundary a knot \( K \subset S^3 \). Denote by \( \tilde{F} \subset \Sigma^m(F) \) the fixed locus of the covering action of \( \Sigma^m(F) \). Then there is a unique spin structure \( t_0 \) on \( \Sigma^m(F) \) characterized as follows:

- if \( m \) is odd, the restriction of \( t_0 \) to \( \Sigma^m(F) - \nu\tilde{F} \) is the pull-back \( \tilde{t} \) of the spin structure of \( B^4 - \nu F \) extending over \( B^4 \),
- if \( m \) is even, the restriction of \( t_0 \) to \( \Sigma^m(F) - \nu\tilde{F} \) is \( \tilde{t} \) twisted by the element of \( H^1(\Sigma^m(F) - \nu\tilde{F}, \mathbb{Z}_2) \) supported on the linking circle of \( \tilde{F} \).
We define the canonical spin structure $s_0$ of the three-manifold $\Sigma^m(K)$ as the restriction of the spin structure $t_0 \in \text{Spin}^c(\Sigma^m(F))$ of Lemma 3.3 to $\Sigma^m(K) = \partial(\Sigma^m(F))$, where $F \subset B^4$ denotes a pushed-in Seifert surface of $K \subset S^3$.

**Lemma 3.4.** Let $C^\text{Spin}_{\mathbb{Q}}$ denote the subgroup of $C_{\mathbb{Q}}$ spanned by the triples $(Y, K, s)$ with $s$ spin. Let $m = p^r$ be a power of a prime. Then the map $\Sigma^m : K \mapsto (\Sigma^m(K), \tilde{K}, s_0)$ descends to a group homomorphism $\Sigma^m : C \rightarrow C^\text{Spin}_{\mathbb{Q}}$.

*Proof.* Since the $m$-fold cyclic branched cover of the two-sphere branched on two points is the two-sphere, we conclude that the map $\Sigma^m$ respects connected sums. Thus, it is enough to prove that if $K$ is a slice knot then $(\Sigma^m(K), \tilde{K}, s_0)$ is rationally slice.

Suppose that $K \subset S^3$ bounds a smooth disk $\Delta \subset B^4$. By taking the $m$-fold cyclic branched cover of $\Delta$ we get a rational homology ball $\Sigma^m(\Delta)$. In $\Sigma^m(\Delta)$ the knot $\tilde{K} \subset \partial\Sigma^m(\Delta)$ bounds a smooth disk $\tilde{\Delta}$, namely the fixed locus of the covering action of $\Sigma^m(F)$. Furthermore, the spin structure $t_0$ of Lemma 3.3 provides a spin extension of $s_0$ to $\Sigma^m(F)$. \hfill \Box

**Theorem 3.5.** Let $C \subset \mathbb{R}^2$ be a south-west region, and $m = p^r$ a power of a prime. Given a knot $K \subset S^3$ set $\Upsilon^C_m(K) = \Upsilon^C(\CFK^\infty(\Sigma^m(K), \tilde{K}, s_0))$. Then $\Upsilon^C_m(K)$ is a knot concordance invariant.

*Proof.* The result follows by combining Lemma 2.7, Lemma 3.4 and Proposition 3.1. \hfill \Box

**Remark 3.2.** Using south-west regions which are symmetric with respect to the $x = y$ axis, one can construct further invariants $\overline{\Upsilon}^C_m(K)$ and $\overline{\Upsilon}^C_m(K)$ by means of the involutive Heegaard Floer homology [14].

For a given cohomology class $\xi \in H^2(\Sigma^m(K); \mathbb{Z}) \simeq H_1(\Sigma^m(K); \mathbb{Z})$ we can set

$$\Upsilon^C_\xi (K) = \Upsilon^C(\CFK^\infty(\Sigma^m(K), \tilde{K}, s_0 + \xi)),$$

where $s_0 + \xi$ denotes the $\text{spin}^c$ structure we get from $s_0$ by twisting it with $\xi$. The following result is a straightforward adaptation of [14] Theorem 1.1, and provides a way to obtain some additional concordance information from the construction above.

**Theorem 3.6.** Let $K \subset S^3$ be a knot. Suppose that $m = p^r$ is a power of a prime and set

$$\text{det}_m(K) = \prod_{i=0}^{m-1} |\Delta_K(\omega^i)|$$

where $\omega$ is a primitive $m$-th root of unity. If $K$ is a slice knot then there exists a subgroup $G < H^2(\Sigma^m(K); \mathbb{Z})$ of cardinality $\sqrt{\text{det}_m(K)}$ such that $\Upsilon^C_\xi (K) = 0$ for all $\xi \in G$.

*Proof.* By the previous discussion, if $K$ is a slice knot, then $\text{det}_m(K)$ is a square. Indeed, $\text{det}_m(K)$ computes the cardinality of $H_1(\Sigma^m(K); \mathbb{Z})$, which is necessarily a square whenever $\Sigma^m(K)$ bounds a rational homology ball.

If $K$ is a slice knot, then $\Sigma^m(K)$ bounds a rational homology ball $W$ to which the spin structure $s_0$ of Lemma 3.3 extends. If $G < H^2(\Sigma^m(K), \mathbb{Z})$ denotes the image of the connecting homomorphism $\delta : H^2(W; \mathbb{Z}) \rightarrow H^2(Y; \mathbb{Z})$ of the long exact sequence for the pair $(W, \partial W)$, then $s_0 + \xi$ extends to a Spin$^c$ structure of $W$ for each $\xi \in G$. More precisely, if $t_0$ denotes the spin$^c$ structure extending $s_0$ then $\partial(W, t_0 + \xi') = (\Sigma^m(K), s_0 + \xi)$ where $\xi' \in H^2(W; \mathbb{Z})$ is a class such that $\delta(\xi') = \xi$. \hfill \Box
K"unneth formula there is an isomorphism respectively; we shall prove that $\Upsilon_{t,0}(K,s_0+\xi)$ represents a spin$^c$ rationally slice knot. Thus, as consequence of Proposition 3.1

\[
\Upsilon^C_K(K) = \Upsilon^C(CFK^\infty(\Sigma^m(K),\bar{K},s_0+\xi)) = \Upsilon^C(CFK^\infty(S^3,U,u)) = 0,
\]

where the last identity follows from the normalization condition on the south-west regions. A careful check with the long exact sequence of the pair reveals that indeed $|G| = \sqrt{\det_m(K)}$, proving the claim.

\[\Box\]

4. Homomorphisms from the Knot Concordance group

The Upsilon-function $\Upsilon_K$ of [25] can be defined along the same ideas, by using special south-west regions. (This reformulation of the invariants is due to Livingston [22].) Indeed, for $t \in [0,2]$ let us consider the half-plane

\[H_t = \{(x,y) \in \mathbb{R}^2 \mid y \leq \frac{t}{t-x}\}.
\]

Since $H_t$ (for the chosen $t \in [0,2]$) is a south-west region, we get an invariant $\Upsilon^{H_t}(K_*)$ for any knot type chain complex $K_*$. Define $\Upsilon_t(K_*) = -2 \cdot \Upsilon^{H_t}(K_*)$.

**Proposition 4.1.** $\Upsilon_t: CFK/\sim \to \mathbb{R}$ is a group homomorphism for each $t \in [0,2]$.

**Proof.** Let $K_*$ and $K'_*$ be two knot type complexes with correction terms $d$ and $d'$ respectively; we shall prove that $\Upsilon_t(K_* \otimes K'_*) = \Upsilon_t(K_*) + \Upsilon_t(K'_*)$. According to the K"unneth formula there is an isomorphism

\[H_*(K_* \otimes \mathbb{Z}_2) \otimes_{\mathbb{Z}_2[U,U^{-1}]} H_*(K'_*) \to H_*(K_* \otimes \mathbb{Z}_2[U,U^{-1}]) \cong \mathbb{Z}_2[U,U^{-1}]_{(d+d')},
\]

given at the chain level by $[\xi] \otimes [\eta] \mapsto [\xi \otimes \eta]$. Thus

\[
\Upsilon^{H_t}(K_* \otimes K'_*) = \min \left\{ \frac{t}{2} A(\xi_i \otimes \eta_j) + \left(1 - \frac{t}{2}\right) j(\xi_i \otimes \eta_j) \right\}
\]

\[= \min \left\{ \frac{t}{2} (A(\xi_i) + A(\eta_j)) + \left(1 - \frac{t}{2}\right) (j(\xi_i) + j(\eta_j)) \right\}
\]

\[= \min \left\{ \frac{t}{2} A(\xi_i) + \left(1 - \frac{t}{2}\right) (\eta_j) \right\} + \min \left\{ \frac{t}{2} A(\eta_j) + \left(1 - \frac{t}{2}\right) (\xi_i) \right\}
\]

where $\xi_1,\ldots,\xi_m$ represent the generators of $K_*$ with Maslov grading $d$, and $\eta_1,\ldots,\eta_s$ denote the generators of $K'_*$ with Maslov grading $d'$.

Lemma 2.7, Theorem 3.4 and Proposition 4.1 imply:

**Theorem 4.2.** Let $m = p^r$ be a prime power. For a knot $K \subset S^3$ set $\Upsilon_{K,m}(t) = \Upsilon_t(CFK^\infty(\Sigma^m(K),\bar{K},s_0))$. Then the map $K \mapsto \Upsilon_{K,m}(t)$ descends to a group homomorphism $C \to C^{0}[0,2]$.

One can also form a spin$^c$ refined versions of these invariants.

**Theorem 4.3.** Let $m = p^r$ be a prime power. For a knot $K \subset S^3$, and a cohomology class $\xi \in H^2(\Sigma^m(K);\mathbb{Z})$ set

\[\Upsilon_{K,\xi}(t) = \Upsilon_t(CFK^\infty(\Sigma^m(K),\bar{K},s_0+\xi)) \]
If \( K \) and \( K' \) are concordant then there exists a subgroup \( G \subset H^2(\Sigma^m(K); \mathbb{Z}) \times H^2(\Sigma^m(K'); \mathbb{Z}) \) with \( |G| = \sqrt{\det_m(K) \cdot \det_m(K')} \) such that \( \Upsilon_{K,\xi}(t) = \Upsilon_{K',\xi'}(t) \) for each \((\xi, \xi') \in G\). \( \square \)

The following theorem gives obstructions to finite concordance order.

**Theorem 4.4.** Let \( K \subset S^3 \) be a knot and \( p \) a prime. Let \( \mathcal{H}_p \) denote the set of subgroups of \( H^2(\Sigma^2(K); \mathbb{Z}) \) of order \( p \). Set

\[
\mathcal{S}_1(K, p) = \min \left\{ \left| \sum_{H \in \mathcal{H}_p} \sum_{\xi \in H} \Upsilon_{K,\xi}(t) \right| : n_H \in \mathbb{Z}_{\geq 0}, \sum_{H \in \mathcal{H}_p} n_H > 0 \right\},
\]

If \( K \) has finite order in the smooth concordance group then \( \mathcal{S}_1(K, p) \equiv 0 \).

**Proof.** A similar statement already appeared in [11], we just follow their argument. If \( K \# \ldots \# K = 0 \) in the knot concordance group then, for some \( n > 0 \), there is a subgroup \( G \subset H^2(\Sigma^2(K); \mathbb{Z}) \times \cdots \times H^2(\Sigma^2(K); \mathbb{Z}) \) with \( |G| = \det(K)^2 \) such that

\[
0 = \Upsilon_{K\# \ldots \# K,\xi}(t) = \sum_{i=1}^{n} \Upsilon_{K,\xi_i}(t)
\]

for each \( \xi = (\xi_1, \ldots, \xi_n) \in G \). We used the identity \( \Upsilon_{K\# K',\xi + \xi'}(t) = \Upsilon_{K,\xi}(t) + \Upsilon_{K',\xi'}(t) \), which follows from [28] Section 7 and Proposition [4.1].

Given a prime \( p \), if \( p \) does not divide \( \det(K) = |H^2(\Sigma^2(K); \mathbb{Z})| \) then by Lagrange’s theorem \( \mathcal{H}_p = \emptyset \). If \( p \) does divide \( \det(K) \), then it also divides \( |G| \) and Cauchy’s theorem guarantees the existence of an order \( p \) element \( \xi = (\xi_1, \ldots, \xi_n) \) in \( G \). Thus

\[
0 = \sum_{j=0}^{p-1} \Upsilon_{K\# \ldots \# K,\xi_j}(t) = \sum_{j=0}^{p-1} \sum_{i=1}^{n} \Upsilon_{K,\xi_i}(t) = \sum_{i=1}^{n} \sum_{j=0}^{p-1} \Upsilon_{K,\xi_i}(t) = \sum_{i=1}^{n} \Upsilon_{K,\xi}(t),
\]

where \( H_i \subset H^2(\Sigma^2(K); \mathbb{Z}) \) denotes the subgroup generated by \( \xi_i \) in \( H^2(\Sigma^2(K); \mathbb{Z}) \). \( \square \)

### 5. Alternating Torus Knots

Alternating torus knots are those of the form \( T_{2,p} \), for some odd integer \( p = 2n + 1 \). The branched double cover of \( T_{2,p} \) is the lens space \( L(p, 1) \). In what follows the lift of \( T_{2,p} \) along the branched covering \( \pi : L(p, 1) \to S^3 \) will be denoted by \( \tilde{T}_{2,p} \).

Let \( K_{p,q} \) denote the 2-bridge knot corresponding to \( \frac{p}{q} \) (with \( p > q > 0 \), \( p \) odd). Notice that the alternating torus knot \( T_{2,2n+1} \) is isotopic to the 2-bridge knot \( K_{p,q} \) with parameters \( p = 2n + 1 \) and \( q = 1 \). In [10] Grigsby proved the existence\(^1\) of a graded quasi-isomorphism

\[
L : \overset{\circ}{CFK}(K_{p,q}) \to \overset{\circ}{CFK}(L(p, q), \tilde{K}_{p,q}, s_0),
\]

where \( s_0 \) denotes the only spin structure of \( L(p, q) \).

In this section we are going to prove Theorem 1.2. Further consequences are going to be outlined at the end of this section.

\(^1\)The actual isomorphism is between the “hat” versions of \( HFK \); we will address the suitable extension in Section 5.1.
5.1. Combinatorial Knot Floer homology. In [23] Manolescu, Ozsváth and Sarkar gave a combinatorial description of $HFK^\circ$ for knots in the 3-sphere using grid diagrams. This construction has been extended by Baker, Grigsby and Hedden to the case of knots in lens spaces. We will recall their definitions in the specific relevant cases, pointing the interested reader to their paper [5].

Given a lens space $L(p, q) = S^3_{p\over q}(\emptyset)$ with $p > q$ and $p$ odd, there is a distinguished choice for the affine isomorphism between $Spin^c(L(p, q))$ and $H_1(L(p, q); \mathbb{Z})$, when the unique spin structure $s_0$ is identified with the trivial homology class. Therefore in what follows we will adopt the convention of labelling $s \in Spin^c(L(p, q))$ by a number $h \in \{-p^{-1}_2, \ldots, p^{-1}_2\}$; to such $h$ we associate the spin$^c$ structure corresponding to $h \in H_1(L(p, q); \mathbb{Z}) \cong \mathbb{Z}_p$. Notice that with the conventions above we have that $s_0 + h = s_0 - h$, where the bar denotes the conjugation on spin$^c$ structures.

A twisted grid diagram for $L(p, 1)$ is a planar representation of a genus one Heegaard diagram for $L(p, 1)$, produced by the minimally intersecting one by doubling both curves. We choose to draw this diagram as shown in Figure 2 where each little square has edges of length one. This is a $2 \times 2p$ grid, with a specific identification of its boundary: the left and right edges of the grid are identified as $(0, t) \sim (2p, t)$ with $t \in [0, 2]$, while the top part is identified with the bottom after a shift taking $(x, 2)$ to $(x - 2, 0)$ (mod $2p$). The integer $n$ is called the dimension of $G_p$.

By placing in the squares two sets of markings $X = \{X_0, X_1\}$ and $\emptyset = \{O_0, O_1\}$, we get a twisted grid diagram $G_p$, which determines a knot $K$ in $L(p, 1)$. It was shown in [9] that if we are considering the lift of a 2-bridge knot to $L(p, q)$, then the resulting knot can be presented as above.

In the case of the lift of $T_{2,2n+1}$ to $L(2n + 1, 1)$, we get a $2 \times 2(2n + 1)$ grid with $\emptyset = \{0, 1\}$ and $X = \{2n + 1, 2n + 2\}$, where the notation means that we are placing the first $\emptyset$ marking in the center of the 0-th square from the left in the bottom-most row of $G_p$, and the second $\emptyset$ in the first box on the top row, and likewise for the $X$s. One example is shown in Figure 2.

Recall that the generators of the knot Floer complex are given by intersections of the $\alpha$- and $\beta$-curves determining the Heegaard splitting. Here the generating set is given by bijections between the horizontal and vertical circles (called $\alpha_0, \alpha_1$ and $\beta_0, \beta_1$ respectively) in the grid, after the identifications. We require that the two points of a generator lie on different curves.

Since each pair $(\alpha_i, \beta_j)$ intersect exactly $p$ times, it is easy to show that the generating set $S(G)$ is in bijection with $\mathbb{S}_2 \times \mathbb{Z}_p^2$. Generators corresponding to $Id_{\mathbb{S}_2} \times (a_0, a_1)$ will be denoted by $x_{a_0,a_1}$, while those of the form $(12) \times (a_0, a_1)$ by $y_{a_0,a_1}$. The two pairs $(a, b) \in \mathbb{Z}_p^2$ will be called the $p$-coordinates of the generator.

Given such a multi-pointed grid $G_p$, representing the pair $(L(p, 1), \tilde{T}_{2,p})$, the complex $GC^\infty(G_p)$ is the free $R^\infty$-module generated by $S(G_p)$. The specific choice of the base ring, together with the choice of a differential, will determine the flavour of grid homology we will consider. In what follows we will restrict to $R^\infty = \mathbb{Z}_2[\upsilon_0^\pm 1, \upsilon_1^\pm 1]$ or $R^- = \mathbb{Z}_2[\upsilon_0, \upsilon_1]$, corresponding respectively to the $\infty$ and minus versions of grid
homology. The variables \( V_i \) act on the complex, and can be thus thought of as graded endomorphisms; they correspond to the \( \mathbb{O} \)-markings.

We can associate three numbers to a generator \( x \in S(G_p) \). The first is the Maslov grading \( M(x) \in \mathbb{Q} \), which behaves as a homological degree, decreasing by one under the action of the differential; the second is the Alexander grading \( A(x) \in \mathbb{Z} \), which is preserved by the differential. Both these gradings can be combinatorially defined from the grid as explained in \([9]\). Finally we can associate to \( x \) a spin\(^c\) structure \( s(x) \in \text{Spin}^c(L(p,1)) \cong \mathbb{Z}_p \) following the recipe of \([5]\) Section 2.2: if the \( p \)-coordinates of \( x \) are \((a,b)\), then \( s(x) \equiv a + b \) (mod \( p \)).

Each \( V_i \) decreases the Maslov degree by two, the Alexander degree by one, and does not change the spin\(^c\) structure. If \( V_0^*V_1^*x \in \mathbb{Z}_2[V_0^{\pm 1}, V_1^{\pm 1}](S(G_p)) \), then the number \( -r - s \) of \( V_i \) variables is called the algebraic filtration, and is denoted by \( j(V_0^*V_1^*x) \).

The differential for the \( \infty \) flavour is the \( \mathbb{Z}_2[V_0^{\pm 1}, V_1^{\pm 1}] \)-chain map defined as follows:

\[
\partial^\infty(x) = \sum_{y \in S(G)} \sum_{r \in \text{Rect}^\infty(x,y)} \sum_{r \cap X = \emptyset} V_0^{O_0(r)} V_1^{O_1(r)} \cdot y \tag{3}
\]

In Equation (3), \( \text{Rect}^\infty(x,y) \) denotes the set of (oriented) empty rectangles \( r \) embedded in the grid, such that the edges of \( r \) are alternatively on \( \alpha \) and \( \beta \) curves, and one component of \( x \) is in the lower-left vertex of \( r \); a rectangle is empty if \( \hat{r} \) does not contain any component of \( x \) or \( y \). Note that in the expression (3) we are also requiring trivial intersection between rectangles and \( X \) markings.

To obtain the minus flavour, keep the same differential and restrict the base ring to \( \mathbb{Z}_2[V_0, V_1] \). If we impose \( V_1 = 0 \) at the complex level, we obtain a complex computing the hat version of knot Floer homology. These are finitely generated modules, over \( \mathbb{Z}_2[U^{\pm 1}], \mathbb{Z}_2[U] \) and \( \mathbb{Z}_2 \) respectively. Here \( U \) is the map\(^2\) induced in homology by either of the \( V_i \)s.

**Remark 5.1.** If we fix an intersection point between one \( \alpha \) and one \( \beta \) curve, and \( i \in \mathbb{Z}_p \), there is only one generator \( x \in S(G)_p \) having that intersection as a component, and such that \( s(x) = i \).

**Remark 5.2.** The quasi-isomorphisms from \([10]\)

\[
L : \widetilde{CFK}(K_{p,q}) \longrightarrow \widetilde{CFK}(L(p,q), \tilde{K}_{p,q}, s_0)
\]

induce quasi-isomorphisms on the other flavours (i.e. the filtered — and \( \infty \) versions) as well. This follows from the fact that \( L \) defined at the complex level is a grading preserving isomorphism of bi-graded vector spaces, and in this case both complexes have trivial differential. This implies that there can only be horizontal and vertical differentials, dictated by the spectral sequence to \( \widehat{HF} \) of the underlying manifold (which is an \( L \)-space in both the domain and codomain of \( L \)).

The purpose of the next section will be to use this combinatorial description for a recursive computation of \( GC^\infty(L(2n+1,1), \bar{T}_{2n+1,2}, s_0 + h) \). Recall that thanks to \([5]\) Theorem 1.1, we know that this complex is in fact chain homotopic to its holomorphic counterpart \( \mathcal{CFK}^\infty(L(2n+1,1), \bar{T}_{2n+1,2}, s_0 + h) \).

\(^2\)This degree is usually \( \mathbb{Q} \)-valued, but since we will only be dealing with null-homologous knots, we choose to keep things as simple as possible.

\(^3\)The action of the two maps induced by \( V_0 \) and \( V_1 \) coincide in homology.
5.2. Computations. If \( p = 2n + 1 \) is an odd integer, and \( h \in \{0, \ldots, n\} \) we want to prove the existence of the following quasi-isomorphisms:

\[
CFK^\circ(L(p, 1), \widetilde{T}_{2,p}, s_0 \pm h) \simeq CFK^\circ(T_{2,p-2h}).
\]  (4)

Note that there will be a shift in the Maslov grading, given by the difference in the correction terms, which can be computed using the recursive formula in [26, Section 4.1].

We can prove the existence of the isomorphisms in Equation (4) by constructing a graded chain map

\[
\widetilde{F}_{p,h} : CFK^\circ(L(p, 1), \widetilde{T}_{2,p}, s_0 + h) \to CFK^\circ(L(p - 2h, 1), \widetilde{T}_{2,p-2h}, s_0),
\]

and post composing with the suitable isomorphism \( L \). Notice that we can write \( \widetilde{F}_{p,h} \) as the composition of some more elementary maps

\[
F_{p,h} : CFK^\circ(L(p, 1), \widetilde{T}_{2,p}, s_0 + h) \to CFK^\circ(L(p - 2, 1), \widetilde{T}_{2,p-2}, s_0 + h - 1),
\]  (5)

shifting the spin\(^c\) structure by one and decreasing \( p \) by two, as shown in Figure 3. We can define the analogous maps \( \widetilde{F}_{p,h} \) by precomposing \( F_{p,h} \) with conjugation on spin\(^c\) structures.

The grid complex \( GC^\circ(L(p - 2, 1), \widetilde{T}_{2,p-2}, s_0 + h - 1) \) has four generators less than \( GC^\circ(L(p, 1), \widetilde{T}_{2,p}, s_0 + h) \). We will choose some generators to be removed from the complex associated to \( \widetilde{T}_{2,p} \) in such a way that we are cancelling precisely the four generators that comprise an acyclic subcomplex, and their cancellation induces the needed quasi-isomorphism.

\[
\begin{array}{cccccc}
-3 & -2 & -1 & 0 & 1 & 2 & 3 \\
\end{array}
\]

\[
\begin{array}{cccccc}
F_{5,2} & F_{5,1} & F_{5,2} & F_{5,1} & F_{5,2} & F_{5,1} \\
\end{array}
\]

\[
\begin{array}{cccccc}
F_{7,2} & F_{7,1} & F_{7,2} & F_{7,1} & F_{7,2} & F_{7,1} \\
\end{array}
\]

\[
\begin{array}{cccccc}
L(3,1) & L(5,1) & L(7,1) \\
\end{array}
\]

**Figure 3.** How the maps \( F_{p,h} \) fit together. The horizontal label denotes the spin\(^c\) structures in the lens space written on the right. Stars represent the corresponding knot Floer homology groups.

Let us introduce some objects that will come into play in the proof of Theorem 1.2. These will be some model complexes, quasi-isomorphic to \( GC^\circ(L(p, 1), \widetilde{T}_{2,p}, s_0 + h) \) in a given Alexander degree.

An *electric pole* of length \( e \geq 0 \) is the graded complex over \( \mathbb{Z}_2 \) described in Figure 4. It consists of \( 2e + 1 \) generators and \( 4e - 2 \) differentials, denoted as dots and arrows respectively. If \( e = 0 \) the pole consists of a single generator. All generators in a pole have the same Alexander degrees.

A *wire* of length \( w > 0 \) is a graded complex composed by \( 2w + 2 \) generators and \( 4w \) differentials, as shown in Figure 5. The differentials in this case carry a label, specifying if they are acting as multiplication by \( V_0 \) or \( V_1 \).

We can form a new complex by “fusing” together two electric poles (of the same length) and a wire, obtaining a complex whose homology has rank 1, generated by the circled generator in Figure 6. More formally, consider two electric poles of length \( e \)
and a wire of length $w$, and identify the two leftmost generators of one pole with the rightmost of the wire, then identify the two leftmost generators of the other pole with the leftmost of the wire, as depicted in Figure 6. We denote this complex as $C[e, w]$. If $e = 0$, each pole is composed by a single generator, and the two leftmost arrows in the wire converge on the left one, while the rightmost are the differentials of the right one, as shown in the bottom of Figure 6. Note that $C[e, w]$ has $2w + 4e$ generators.

We will now prove that the graded complex $GC^\infty(G_p, s_0 + h)$ can be built from unions of wires and poles.

**Proposition 5.1.** The complex $GC^\infty(L(p, 1), \tilde{T}_{2,p}, s_0 \pm h)$ is quasi-isomorphic to $C[h, p - 2h] \otimes F[V_0^\pm 1, V_1^\pm 1]$, which in turn is quasi-isomorphic to $CFK^\infty(T_{2,p-2h})$.

This means that the height of the poles is controlled by the “distance” from the spin structure $s_0$; in the following proof we are going to show how to shorten each pole without changing the homology, hence proving that the complex is completely determined by the length of its wires.

**Proof.** As before, let us denote by $G_p$ the grid for the lift of $T_{2,p}$ to $L(p, 1)$. We first need to argue that each generator can have at most 2 differentials emanating from it.
Lemma 5.2. If \( x \) denotes a generator in \( S(G_p) \), then there are at most 2 differentials emanating from \( x \).

The proof of the Lemma is deferred to the end of this subsection. We will subdivide the generators of \( S(G_p) \) in different families, and give a general formula for the differential on each. First of all note that, since markings of either kind are grouped together, they act as “walls” for rectangles: if the two components of a generator \( x \) are intertwined with the \( X \) markings, then every empty rectangle starting from \( x \) must intersect an \( O \) marking, resulting in the multiplication by a \( V_i \) variable.

On the other hand, if the two components are on the same side with respect to some type of marking, the differential of \( x \) will be composed by elements with the same property (and there is not going to be any multiplication by \( V_i \)). This will not hold for 4 sporadic cases, which will provide the “attachment” between wires and poles.

Let \( A_p \) denote the set of generators in \( S(G_p) \) whose components do not intertwine with the markings, and \( B_p \) the remaining ones. Apart from 4 special cases treated separately, we will prove that each generator \( x \in A_p \) has differential of the form \( \partial(x) = x' + x'' \), for distinct \( x', x'' \in A_p \), while if \( x \in B_p \) then either \( \partial(x) = V_i(x' + x'') \) or \( \partial(x) = V_i x' + V_{i+1} x'' \) for some \( i \) (indices modulo 2). In the remaining sporadic cases, we will also explicitly determine the differential.

Note that we know the number of generators in each spin\(^c\) structure, and we will determine explicitly the differential; since we are considering the graded version of \( GC^\infty \), and for a fixed Alexander degree the graph induced by the differential is connected, we only need to determine the degree of one element in order to determine the whole complex \( GC^\infty(L(p,1), \tilde{T}_{2,p}, s) \). In all cases it is easy to find two generators connected to \( x \) by empty rectangles not intersecting the \( X \) markings. By Lemma 5.2 we know that these are the only ones.

\[
\partial(x_{a,b}) = \begin{cases} 
  y_{b,a} + y_{a-1,b+1} & \text{if } x \in A_p, a \leq b \\
  y_{a,b} + y_{b-1,a+1} & \text{if } x \in A_p, b \leq a \\
  V_0 y_{a,b} + V_1 y_{b-1,a+1} & \text{if } x \in B_p, a \leq b \\
  V_0 (y_{a-1,b+1} + y_{b,a}) & \text{if } x \in B_p, b \leq a 
\end{cases}
\]
A change of basis: \( a' = a + b, \quad b' = b \). Cancelling the acyclic pair \((c, a + b)\) lowers the height of an electric pole by 1.

For each spin \(s\) structure \(s_0 \pm \h\), with \(\h \neq 0\), we can find 4 generators with a slightly different behaviour. These are the generators such that one component is positioned on the lower left vertex of a square containing an \(\mathcal{X}\) or an \(\mathcal{O}\) marking. We can write them as \(y_{p-1,*}, y_{*',p+1}\) in the case of \(\mathcal{X}\) markings, and \(x_{0,*}, x_{*',0}\) for the \(\mathcal{O}'s\). The values of \(*\) and \(*'\) are uniquely determined by \(\h\). Their differentials are:

\[
\partial(z) = \begin{cases} 
0 & \text{if } z = y_{p-1,*} \\
0 & \text{if } z = y_{*',p+1} \\
V_0y_{0,*} + V_1y_{p-1,*+1} & \text{if } z = x_{0,*} \\
V_0y_{*0} + V_1y_{p-1,*+1} & \text{if } z = x_{*0} 
\end{cases}
\]

Putting all differentials together, we see that, in a fixed Alexander degree the complex \(GC_{\infty}(L(p,1), \tilde{T}_{2,p}, s_0 \pm \h)\) is indeed composed by two electric poles of height \(\h\), attached to a wire of length \(p - 2\h\), as shown in Figure 6.

It follows that \(CFK_{\infty}(L(p,1), \tilde{T}_{2,p}, s_0 \pm \h)\) is isomorphic to the free \(\mathbb{Z}_2[U, U^{-1}]\)-module generated by \(C[h, p-2h]\).

Now we just need to prove that \(C[h, p-2h]\) has the same homology as of \(CFK_{\infty}(T_{2,p-2h})\); this can be done by defining at the grid level the quasi-isomorphisms \(F_{p,h}\).

However, it is immediate to note that the change of basis shown in Figure 8 induces a quasi-isomorphism between \(C[h, p-2h]\) and \(C[h-1, p-2h]\).

In other words, by iterating this process \(h\) times, we have proved that

\[
C[e, w] \simeq C[0, w]. \quad (6)
\]

Similar quasi-isomorphisms where used in [7], dealing with a different family of knots in \(L(p,1)\). The idea now is that by composing \(h\) of these maps, we obtain a chain of quasi-isomorphisms from the complex in the spin\(^c\) structure \(s_0 + \h\) to the complex in the spin structure \(s_0\) in \(L(p-2h,1)\). Summing all up, we have proved the existence
of the following chain of quasi-isomorphisms:

\[ \text{GC}^\infty(L(p, 1), \tilde{T}_{2,p}, \mathbf{s}_0 \pm h) \simeq C[h, p - 2h] \otimes F[U] \simeq C[0, p - 2h] \otimes F[U] \simeq \text{GC}^\infty(L(p - 2h, 1), \tilde{T}_{2,p-2h}, \mathbf{s}_0) \simeq \text{CFK}^\infty(T_{2,p-2h}), \]

where

- the first quasi-isomorphism is given by explicitly determining the differential of the first complex;
- the second one is given by shortening the electric poles with the \( h \) applications of the basis change in Figure 8;
- the third is just the inverse of the first one;
- the fourth one is [5, Theorem 1.1];
- the last quasi-isomorphism is Grigsby’s \( L \).

\[ \square \]

**Figure 9.** The rectangles with wavy and filled patter start from the lower component of the gray generator and connect it to the white and black ones respectively. Only the first one has trivial intersection with the \( X \) markings.

**Proof of Lemma 5.2.** It is easy to argue that for a rectangle in \( G_p \) to be empty, it must necessarily have either height or length equal to 1 (recall that the top/bottom identification is a shift by 2). So there can be at most 4 rectangles starting from a generator \( x \in S(G_p) \). We want to show that only two of them are disjoint from the \( X \) markings.

Consider the two rectangles starting from a generator, as in Figure 9. If we assume that the “horizontal” rectangle does not intersect the \( X \) markings, then necessarily the other one will, and vice versa. \( \square \)

### 5.3. Consequences

In the case of alternating knots, invariants coming from Knot Floer homology usually do not yield any interesting information. The following result, despite being well-known [20], points out an interesting way of showing that \( \text{HFK} \) can be used to extract useful information from alternating knots as well.

**Theorem 5.3.** The alternating torus knots \( T_{2,p} \) with \( p \) an odd prime are linearly independent in the concordance group.

**Proof of Theorem 5.3.** Let \( K \) be of the form \( K_+ \# K_- \) with \( K_+ = \#_i a_i T_{2,2n_{i+1}} \) and \( K_- = -\#_j b_j T_{2,2m_{j+1}} \), \( a_i, b_j > 0 \), \( n_i, m_j \geq 1 \) all distinct. Set \( G = H_1(\Sigma(K), \mathbb{Z}), G_+ = H_1(\Sigma(K_+), \mathbb{Z}) = \bigoplus_i \mathbb{Z}/2n_{i+1} \mathbb{Z}, \) and \( G_- = H_1(\Sigma(K_-), \mathbb{Z}) = \bigoplus_j \mathbb{Z}/2m_{j+1} \mathbb{Z} \).

Assume that \( K \sim \varnothing \), then \( \tau_{\xi \pm}(K) = 0 \) for all \( \xi \in M \) for some \( M \subset G \) with \( |M| = \sqrt{|G|} \). Write \( \xi = (\xi_+, \xi_-), \) with \( \xi_+ \in G_+ \) and \( \xi_- \in G_- \). Because of the additivity of the \( \tau \)

\[ \text{There are at most 2 starting from either component, since they are of length/height 1, but it might happen that they coincide.} \]
invariant, one has
\[
\tau_{s_0+\xi}(K) = \tau_{s_0+\xi_+} (\#_i a_i T_{2,2n_i+1} - \tau_{s_0+\xi_-} (\#_j b_j T_{2,2m_j+1})
= \sum_i a_i \tau_{s_0+\xi_+} (T_{2,2n_i+1} - \sum_j b_j \tau_{s_0+\xi_-} (T_{2,2m_j+1})
= \sum_i a_i \tau (T_{2,2n_i+1 - 2|\xi_+|}) - \sum_j b_j \tau (T_{2,2m_j+1 - 2|\xi_-|})
= \sum_i a_i (n_i - |\xi_+|) - \sum_j b_j (m_j - |\xi_-|)
= \left(\sum_i a_i n_i - \sum_{i=1}^k b_j m_j\right) - \left(\sum_i a_i |\xi_+| - \sum_{i=1}^k b_j |\xi_-|\right)
\]
Thus, if \( K \) is slice, the quantity
\[
H(\xi) = \sum_i a_i |\xi_+| - \sum_j b_j |\xi_-| \quad \xi \in M
\tag{7}
\]
should be constant. In fact, since for \( \xi = 0 \) one has \( H(0) = \tau(K) = \sum_i a_i n_i - \sum_j b_j m_j = 0 \), we expect \( H(\xi) \equiv 0 \). On the other hand, because of the assumption on the coefficients of the torus knots being primes (milder conditions can be required here), one can find non-zero \( \xi \in M \) of the form \( \xi = (\xi_+, 0) \). However, for such a \( \xi \) one has \( H(\xi) > 0 \), and we reach a contradiction. \( \square \)

**Remark 5.3.** The argument given above (and indeed, the statement of Theorem 5.3) is not optimal. The same argument works if in a family \( T_{2,2n_i+1} \) all \( 2n_i + 1 \) are powers of different primes. The fact that all alternating torus knots are linearly independent, however, requires a more subtle group theoretic result, which we do not pursue here.

The computations of the previous sections can also be used to deduce Corollary 1.5 (for more about this see [2]).

**Proof of Cor. 1.5.** Write \( 2n + 1 = a^2b \) and \( \det(K) = c^2d \) for \( b, d \) square-free integers. If \( b \neq d \), then the product of the determinants would not be a square, hence the knots \( T_{2,p} \) and \( K \) couldn’t be concordant. Moreover, for each component of \( \tau(\overline{K}) \), there can be at most 2 components of \( -\tau(\overline{T_{2,p}}) \) equal to it by Corollary 1.3 — this means that there can be at most \( 2c^2d = 2c^2b \) zero entries in \( \tau(K \# m(-T_{2,p})) \).

By [11] Theorem 1.1, in order for \( K \# m(-T_{2,p}) \) to be slice (and thus for \( K \) and \( T_{2,p} \) to be concordant), we need \( \sqrt{|\Sigma^2(S^3; K \# m(-T_{2,p}))|} = \sqrt{a^2b^2c^2} = abc \leq 2c^2b \), and the result follows. \( \square \)

Of course the same result holds for any knot such that its \( \tau \)-invariants in the double branched cover are all different, i.e. \( \tau_{s_1} = \tau_{s_2} \iff s_1 = s_2 \) or \( \overline{s_2} \). A stronger result can be obtained by considering Ozsváth-Szabó correction terms \( d(L(p, 1), s) \), which exhibit the same maximal difference as \( \tau \).

**Remark 5.4.** Using a result by Raoux [31], we can determine the slice genus of the lifts \( \overline{T_{2,p}} \). Here by slice genus \( g_s(K) \) of a knot \( K \subset L(p, 1) \), we mean the minimal genus

\( \text{Of course, in this argument one can also use the upsilon invariants we introduced above. In this precise example however it does not make any difference since the upsilon invariant of the involved knots is determined by their } \tau \text{ invariant (the slope at zero).} \)
of a smooth and properly embedded surface Σ in \((W_p, L(p, 1))\), and such that ∂Σ = K, where \(W_p\) is the Euler number \(p\) disk bundle over \(S^2\).

If \(K \subset S^3\) bounds a smooth slice surface \(S\) of genus \(g\), then its lift \(\tilde{K} \subset Σ(K)\) will bound a genus \(g\) surface in the double branched cover of \(D^3\) over \(S\), obtained by lifting \(S\). Hence \(g_*(T_{2,p}) \leq n = \frac{1}{2}(p - 1)\). On the other hand, since \(τ^s(K) \leq g_*(K)\) for every spin\(^c\) structure that extends to \(W_p\), as does \(s_0\), using [31, Corollary 5.4] we have \(g_*(\tilde{T}_{2,p}) = n\).

**Remark 5.5.** By [7, Proposition 25], the knots \(\tilde{T}_{2,p}\) are not concordant to local knots. Also, by [7, Theorem 4] the genus of a PL surface cobounding \(\tilde{T}_{2,p}\) and \(\bigcirc\) in \(L(p, 1) × I\) is at least \(n\). Here, by PL surface, we mean a surface which is smooth everywhere, except for a finite number of singular points, which are cones over knots in \(S^3\).

### 6. Further examples with (1,1)-knots

In this section we perform some further computations in the case of genus one doubly pointed Heegaard diagrams. These are known as (1,1)-knots [32]. Based on these computations we give an alternative proof of Theorem 5.3, and prove an independence result about twist knots.

#### 6.1. (1, 1)-diagrams of alternating torus knots

Note first that the alternating torus knot \(T_{2,2n+1}\) can be given by the toroidal doubly pointed Heegaard diagram in the top-left of Figure 10.

From this picture one can easily find the chain complex \(\mathcal{CFK}^∞(T_{2,2n+1})\), shown in the lower part of Figure 10. The generators are denoted by \(x_i\) for \(i = 1, \ldots, 2n + 1\), and the boundary maps are given by the bigons visible on the picture. (There are
no more nontrivial components of the boundary, since the Maslov index one domains connecting any further pairs contain domains of negative multiplicity.)

The generators of the chain complex of $\mathcal{CFK}^\infty(K)$ for a (1,1)-knot are easy to determine: these are the intersection points of the unique $\alpha$- and the unique $\beta$-curve. The boundary map is defined by counting holomorphic maps from the unit disk $\mathbb{D}$ to the Heegaard torus $T^2$, with the usual (Floer theoretic) boundary conditions. The map $\mathbb{D} \to T^2$ is not necessarily injective, but once we pass to the universal cover $\mathbb{C}$ of $T^2$ (and lift one of the intersection points to one of its preimages), the boundary map can be determined by identifying embedded bigons in the universal cover. As we will see, in some cases it is sufficient to consider one or two fundamental domains, making the computation much simpler.

Now consider the double branched cover $\Sigma(T_{2,2n+1})$; a 3-manifold diffeomorphic to the lens space $L(2n + 1, 1)$. The lift of the branch curve $T_{2,2n+1} \subset S^3$ provides a null-homologous knot $\tilde{T}_{2,2n+1} \subset \Sigma(T_{2,2n+1})$. The pullback of $\alpha, \beta \subset T^2$ to the double branched cover will be denoted by $\alpha_1, \alpha_2$ and $\beta_1, \beta_2$. In this way we get a genus-2 Heegaard diagram $\mathcal{H} = (\Sigma_2, \{\alpha_1, \alpha_2\}, \{\beta_1, \beta_2\})$ for $\Sigma(T_{2,2n+1})$. The intersection points $T_{a} \cap T_{\beta}$ can be easily described as follows. Let $a_i, b_i$ denote the two points over $x_i$, and assume that $a_i \in \alpha_1$ (and so $b_i \in \alpha_2$). We also assume that $a_1 \in \alpha_1 \cap \beta_1$ (and hence $b_1 \in \alpha_2 \cap \beta_2$). There are two types of points $x_i$: we say that $x_i$ is homogeneous if $a_i \in \beta_1$ (so by our choice $x_1$ is homogeneous) and inhomogeneous if $a_i \in \beta_2$.

Since the bigons in the fundamental domain appearing in the boundary maps all lift to rectangles (since all these bigons contain a unique basepoint), they connect homogeneous points with inhomogeneous ones, hence we conclude that $x_1, \ldots, x_n$ and $x_{2n+1}$ are homogeneous and $x_{n+1}, \ldots, x_{2n}$ are inhomogeneous.

This shows that the pull-back diagram in the double branched cover has $(n+1)^2 + n^2$ generators in the Heegaard Floer chain complex: these are $\{(a_i, b_j)\}$ where either both $i, j$ are homogeneous or both non-homogeneous. It is easy to see that $(a_i, b_i)$ and $(a_j, b_j)$ are in the same spin$^c$ structure (since the bigons connecting the various $x_i$'s lift to rectangles connecting the various $(a_i, b_i)$'s). Indeed

**Lemma 6.1.** The generators $(a_i, b_i)$ represent the spin structure $s_0$ of $\Sigma(T_{2,2n+1})$. The pairs $(a_i, b_j)$ and $(a_k, b_l)$ represent the same spin$^c$ structure if and only $i - j = k - l$.

**Proof.** The elements $(a_i, b_i)$ all represent the same spin$^c$ structure since they can be connected by domains (the pull-backs of the bigons from downstairs), and since this spin$^c$ structure is conjugation invariant, it must be the spin structure $s_0$. Now comparing any $(a_i, b_j)$ to $(a_i, b_i)$, and noticing that the spin$^c$ structure of $(a_i, b_j)$ is given by twisting $s_0$ with $(j - i)$-times a generator of $H_1$ of the double branched cover, we conclude the proof.

Recall that the pairs come with Alexander and Maslov gradings, and indeed the Alexander gradings are relatively easy to compute in terms of the Alexander gradings of the $x_i$'s.

**Lemma 6.2** (Levine, [18]). The Alexander grading $A(a_i, b_j)$ of $(a_i, b_j)$ is equal to $\frac{1}{2}(A(x_i) + A(x_j))$. In particular, $A(a_n, b_n) = n$, $A(a_{2n+1}, b_{2n+1}) = -n$ and for all further generator $|A(a_i, b_j)| < n$.

We already know that the knot Floer complex for $(\Sigma(T_{2,2n+1}), \tilde{T}_{2,2n+1}, s_0)$ for the spin structure $s_0$ is actually isomorphic to the knot Floer complex of $T_{2,2n+1} \subset S^3$, hence we get the $\Upsilon$-invariant in this spin$^c$ structure. All nontrivial components of $\partial$ in
\( \text{CFK}^\infty(\Sigma(T_{2,2n+1}, \tilde{T}_{2,2n+1}, s_0)) \) are defined by bigons in the fundamental domain of the \((1,1)\)-diagram we are working with. These bigons lift to rectangles in the double branched cover (since each bigon contains a unique \(z\) or \(w\)), hence we get the same maps upstairs in \( \text{CFK}^\infty(\Sigma(T_{2,2n+1}, \tilde{T}_{2,2n+1}, s_0)) \).

The same argument as for \( T_{2,2n+1} \subset S^3 \) then applies and shows that there are no more nonzero components of the boundary map upstairs: any domain with Maslov index 1 connecting further pairs of generators has some negative multiplicity.

**Proof of Theorem 5.3.** The proof is essentially the same as the proof given at the end of Section 5: for a relation we consider the double branched cover along the slice knot, which admits a filling by a rational homology disk, and for all spin\(c\) structures extending from the double branched cover to this 4-manifold, the same linear combination of \( \Upsilon \)-functions as in the relation must vanish. The spin structure extends, hence we get one relation, and then we find an element of the form \((h_+, 0)\) in the metabolizer \( G_+ \oplus G_- = G \), where \( h_+ \) has some nonzero component. By Lemma 6.2 at that component we replace the corresponding value of \( \Upsilon(1) \) with some smaller value, which will result in violating Equation (7), concluding the proof. \( \square \)

6.2. **Twist knots.** The \((1,1)\)-diagram of Figure 11 provides a doubly pointed Heegaard diagram for the twist knot \( TW_n \). The parameter \( n > 0 \) is chosen so, that \( TW_1 \) is the (right-handed) trefoil knot and \( TW_2 \) is the Figure-8 knot.

![Figure 11. (1,1)-diagram of the twist knot \( TW_n \)](image)

In particular, the determinant \( \Delta_{TW_n}(t) \) is equal to \( 2n + 1 \), and for \( n \) odd we have

\[
\Delta_{TW_n}(t) = \frac{n+1}{2} t - n + \frac{n+1}{2} t^{-1},
\]

while for \( n \) even

\[
\Delta_{TW_n}(t) = -\frac{n}{2} t + (n+1) - \frac{n}{2} t^{-1}.
\]

Furthermore, the signature \( \sigma(TW_n) = -1 \) if \( n \) is odd, and \( \sigma(TW_n) = 0 \) if \( n \) is even.

From the diagram we can easily determine the chain complex \( \text{CFK}^\infty \). This can be done by analyzing the bigons in the universal cover of the \((1,1)\)-diagram – in this particular case, in fact, two fundamental domains will suffice to contain all relevant bigons, see Figure 12.

For the schematic picture of the chain complex see Figure 13. Denoting the intersection point corresponding to \( i \) by \( x_i \), we get the following:

**Lemma 6.3.** The Alexander grading \( A(x_i) \) of \( x_i \) is

- 0 if \( i \equiv n + 1 \pmod{2} \),
- 1 if \( i \equiv n \pmod{2} \) and \( i > n + 1 \), and
Figure 12. Two fundamental domains in the universal cover of the 
\((1,1)\)-diagram of \(TW_n\).

Figure 13. The chain complex of the twist knot \(TW_n\).

\[ -1 \text{ if } i \equiv n \pmod{2} \text{ and } i < n + 1. \]

**Proof.** Recall that \(A(x) - A(y) = n_z(\phi) - n_w(\phi)\) for a domain \(\phi\) connecting \(x\) and \(y\). If there is an arrow from \(x_i\) to \(x_j\), then \(A(x_i) - A(x_j) = 1\) if the arrow is decorated by \(z\) and is equal to \(-1\) if the decoration of the arrow is \(w\). Since on the vertical paths of Figure 13 the decorations alternate, and (by symmetry) \(A(x_{n+1}) = 0\), the claim follows at once. \qed

As before, in the double branched cover the \(\alpha\)- and the \(\beta\)-curves lift to \(\alpha_1, \alpha_2\) and \(\beta_1, \beta_2\). Similarly, each intersection point \(x_i\) gives rise to two intersections \(a_i\) and \(b_i\). We will follow the convention that \(a_i \in \alpha_1, b_i \in \alpha_2\), and moreover \(a_1 \in \beta_1\). Then it is not hard to see that \(a_i \in \alpha_1 \cap \beta_1\) if and only if \(i\) is odd (and then \(b_i \in \alpha_2 \cap \beta_2\)) and for even \(i\) we have \(a_i \in \alpha_1 \cap \beta_2\) and \(b_i \in \alpha_2 \cap \beta_1\). Consequently the generators of the Heegaard Floer chain complex of the double branched cover are of the form \((a_i, b_j)\) with the constraint that \(i \equiv j \pmod{2}\).

According to the earlier cited result of Levine, we have that

\[ A(a_i, b_j) = \frac{A(x_i) + A(x_j)}{2}. \]

**Lemma 6.4.** The \(\text{spin}^c\) structure \(s(a_i, b_j)\) can be determined as follows:

- \((a_i, b_j)\) represents the spin structure \(s_0\) on \(\Sigma(TW_n)\) if and only if \(i = j\), and
- \((a_i, b_j)\) and \((a_k, b_\ell)\) are in the same \(\text{spin}^c\) structure if and only if \(i - j = k - \ell\).
Proof. The proof is the direct adaptation of the proof of Lemma 6.1.

A simple corollary of the above:

Corollary 6.5. Suppose that $|i - j| > n + 1$. Then $A(a_i, b_j) = 0$.

According to the last corollary, for $n \geq 1$ there is always a spin$^c$ structure where all generators have $A = 0$, hence the Upsilon-function is constantly zero.

On the other hand, as in the case of torus knots, we immediately see that in the spin structure $s_0$ the chain complex $\mathcal{CFK}^\infty(\Sigma(TW_n), \tilde{TW}_n, s_0)$ is isomorphic to $\mathcal{CFK}^\infty(TW_n)$. Indeed, the previous lemma shows a bijection between the generators, and all bigons of the fundamental domain lift to an embedded rectangle, providing nontrivial boundary maps. (The further nonzero components then are forced by the fact that $\partial^2 = 0$.)

Independence of the family $\{TW_p\}_{p>0, p\neq 4}$ was first established in [6], and can be deduced from Lisca’s work [19]. The above data suffice to show a weaker result about linear independence in the concordance group:

Proposition 6.6. The family $\{TW_p \mid p$ odd and $2p + 1$ is prime$\}$ forms a set of linearly independent elements in the smooth concordance group $\mathcal{C}$.

Proof. As in the case of torus knots, suppose that there exists a linear dependence $\sum k_i TW_{p_i} \sim 0$, and rewrite it as $\sum m_i TW_{p_i} - \sum n_j TW_{q_j} \sim 0$ with $m_i, n_j > 0$.

The double branched cover $Y$ (which is the appropriate connected sum of the double branched covers of the individual knots $TW_p$), bounds a rational homology ball, hence in $H_1(Y; \mathbb{Z})$ there is a metabolizer $M$ as before. Once again, we write $M$ as $M_+ \oplus M_-$. Notice that since the spin structure extends, we have that $\sum m_i - \sum n_j = 0$, or equivalently

$$\sum m_i = \sum n_j.$$  

(This would also follow from the signature values of the knots since we assumed that all $p$ are odd.)

Now suppose that $(h_+, h_-)$ is a nonzero element in the metabolizer $M$. By the same argument as in the proof of Theorem 5.3, an appropriate multiple of this element looks like $(0, h'_-)$ (or $(h'_+, 0)$, but the two cases are completely symmetric). By eventually taking a further multiple, we can assume that at least one component of $h'_-$ is in a spin$^c$ structure, where all generators have Alexander grading equal to zero, hence the $\Upsilon$-function in that spin$^c$ structure is identically zero.

This provides the desired contradiction, since in Equation (8) we do not change the left hand side, but delete some (strictly positive) terms from the right hand side, hence the resulting expression does not hold anymore, contradicting the fact that the spin$^c$ structure extends to the rational homology 4-ball.

Remark 6.1. We expect that for $n$ even the knot $\tilde{TW}_n \subset \Sigma(TW_n)$ has constant zero $\Upsilon$-function in every spin$^c$ structure.
