Thermal Conversion of Waste Plastics into Fuel Oil

Abstract

As a means of converting abundant waste to wealth, thermal conversion of waste plastics of four different types (low and high density polyethylene (LDPE and HDPE), polypropylene (PP) and mixed plastics) was carried out in a batch reactor made of stainless steel at temperatures between 170 and 300°C under atmospheric pressure. The vapor produced from melting the plastics was condensed to form the liquid hydrocarbon (fuel oil) product. Standards were followed for each of the waste plastics during the production process of the liquid fuel oil. The effect of reaction time and product yield were investigated. The physical properties measured include product density and specific gravity. The liquid products formed were characterized using FT-IR spectrometer (Spectrum 100 Perkin-Elmer). The heat combustion properties of the fuels produced were compared using ASTM D240. Also the API gravity and Sulphur content analysis were carried out using the ASTM D4052 and 4053 respectively. The chemical properties of the liquid product were compared for each of the samples and it was found that they vary from each waste plastic. Each of the liquid products contained low sulfur, but each of them varied from each other.

Keywords: Waste-plastic; Liquid-fuel-oil; LDPE; HDPE; PP; Mixed plastics; Thermal-conversion

Abbreviations: LDPE: Low Density Polyethylene; HDPE: High Density Polyethylene; PP: Polypropylene; PE: Polyethylene; PS: Polystyrene; PLF: Pyrolysis Liquid Fuel

Introduction

In the last few decades, there has been a dramatic increase in industrial and urban activities, culminating in the need for people to adopt improved living conditions. This has led to an increase in the use of packaging materials, mainly in the form of plastic. Plastics have become an indispensable part of today’s world. Due to their lightweight, durability, energy efficiency, coupled with ease of production and design flexibility. These polymers are employed in entire gamut of industrial and domestic areas. Plastics are produced from petroleum derivatives and are composed primarily of hydrocarbons, but also contain additives such as antioxidants, colorants and other stabilizers [1]. Today about 129 million tons of plastics are produced annually all over the world, out of which 77 million tons produced from petroleum [1]. Plastics are non-biodegradable polymers, mostly containing carbon, hydrogen, and a few other elements like nitrogen, chlorine. However, some plastics can also be made from renewable materials such as polylactic acid, obtainable from cellulose materials. Plastic products are ubiquitous in modern society because they represent a convenient means to transport purchased goods from the markets, factories, supermarket to the home. Plastic products are plentiful, inexpensive to produce, sturdy yet low weight, and easy to store and transport [2]. Due to its less-biodegradable nature, plastic wastes contribute significantly to the problem of waste management. Disposal of plastic wastes pose a great hazard to the environment and effective method has not been implemented [3].

Nowadays, the production and usage of plastics have increased the percentage of municipal waste more than ever because of modern lifestyle and an urgent need for comfort. Consequently, the menace of ineffective and poor disposal of plastic waste has created serious social and environmental challenges [4]. Of the total amount of municipal solid waste, a small percentage of these wastes are recyclable while the largest percentage is waste plastic. Most plastic wastes are separated into polyethylene (PE) and polypropylene (PP) [3]. Plastic waste is a big issue in most developing countries, because the amount of recycled plastic remains low due to the high investment needs and operating cost [5,6].

However, the possibilities exist for the plastics to be recycled, treated and used as raw material, thereby reducing the large volume of waste and the extent of environmental nuisance the waste constitute to urban streets. Recycling of plastics already occurs on a wide scale. The most attractive technique of chemical feedstock recycling is pyrolysis. Thermal cracking or thermal pyrolysis involves the degradation of the polymeric materials by heating in the absence of oxygen [7]. Pyrolysis is the thermo-chemical decomposition of organic material at high temperatures. This process is a part of de-polymerization, which is in contrast to the creation of plastics which uses polymerization from syngas and crude oil. The liquid product obtained is attractive because its properties has shown its potential for use as a chemical feedstock or fuel [8]. Recycling via pyrolysis is one of the promising methods for recycling waste plastics and involves thermo chemical decomposition of organic and synthetic materials at elevated temperatures in the absence of oxygen to produce fuels. The process is usually conducted at higher temperatures between 500-800°C. These pyrolytic products can be divided into a liquid component, a gaseous component and solid residues [9]. Scheirs et al. [4] compared the waste plastic oil with petroleum products and they found that it can also be used as fuel in compression ignition engines.
Thermal cracking of polyethylene and polypropylene carried out at high temperatures produce an olefin mixture ($C_1-C_4$) and aromatic compounds, including benzene, toluene and xylene while those carried out at lower temperatures (400-500°C) produce three products: a high-calorific value gas, condensable hydrocarbon oil, and waxes [10,11]. A wax product, consisting of paraffin together with a carbonized char is obtained in the reactor during cracking at lower temperatures. The gaseous fraction can be used for the supply of the energy required for the pyrolysis after burning. The liquid element mainly consists of linear olefins and paraffin with $C_{11}-C_{14}$ carbon atoms with only traces of aromatic compounds [11]. Different researchers have studied the effect of temperature and the type of reactor on the pyrolysis of waste plastics [1,3,5,7,11-13]. Pyrolysis and catalytic reforming of municipal plastic waste, which comprise of polyethylene (PE), polypropylene (PP) and polystyrene (PS), as impurities, are also significant. These impurities were acidic and toxic and led to the easy deactivation of the catalyst in the case of the conversion of municipal plastic waste, which have been compared with the thermal degradation products from municipal plastic waste and model mixed plastics [13]. After the process of pyrolysis, wax and carbon black were created. Liquid fuel created from pyrolysis has similar properties to the generic diesel oil and benzene oil. In the present investigation, the recycling of waste products based on PP, LDPE, HDPE, and mixed plastic was examined using pyrolytic method. This study identifies different fractions of liquid fuel from plastic wastes obtained by non-catalyst conventional slow pyrolysis.

**Materials and Experimental Setup**

**Materials**

The thermo chemical conversions of discarded plastic to crude plastic oil were conducted using a stainless steel pyrolysis batch reactor. The system contains a 30 L reactor, connected to a condenser unit via a pipe, which is obliquely projected from the centre of the cover of the reactor. Perkin Elmer FTIR (Fourier Transform Infra-red Spectroscopy) Spectrum-100, employed for analytical purposes. FTIR program set up were elaborated, before sample run, visible light range were 400 - 4000 cm$^{-1}$, taken scan number is 17 and resolution number is 4.

**Experimental setup**

Discarded plastic wastes were collected and sorted by handpicking municipal waste dumps and street litters across Ado Ekiti, Ekiti State, Nigeria. The waste plastics were classified into polyethylene (PE), polypropylene (PP), and polystyrene (PS), which have approximately 20 % of dirty contaminated contents. The plastics were cleaned by soaking for about an hour in water, using detergent. They were thoroughly washed, sun dried for about five hours and shredded. The dried shredded plastic wastes were weighed (ranges from 400 grams to 3kg) and charged into the batch reactor without a catalyst. These plastic types were investigated individually. The reactor was covered using gaskets and sealed with the aid of, gasket seal to avoid leakage. The reactor was then placed on an LPG gas burner and was connected to the condenser and separating system.

A thermocouple was then placed in the reactor and heated gas burner while the temperature was maintained between 170-300°C starting at 170 to 300°C with an increments of 5 to 10°C in order to make the plastics change gradually. In a typical run, the reactor is heated without oxygen. The gaseous products were cooled in the condenser maintained at 5-15°C. The cooled liquid from the process was called pyrolysis liquid fuel (PLF). The pyrolysis process involves the breakdown of large molecules into smaller molecules. Produced hydrocarbon with a small molecular mass can be separated by fractional distillation and then used as fuel and chemicals. The condensed products were measured and the yield of liquid products was determined by dividing the collected material by the weight of feeding plastics. The schematic diagram of the pyrolysis plant used to the produce pyrolysis liquid fuel (PLF) is shown in Figure 1.

**Figure 1:** Pictorial and schematic diagrams of pyrolysis plant.
Results and Discussion

The study of the production of liquid fuel oil from different plastic wastes in a pyrolysis laboratory plant at temperatures between 170-300°C has been conducted. Each experiment run time temperature was monitored properly to prevent overheating of the reactor. In the initial state of the experiments, the temperature profile rose from 170-222°C to melt the solid plastics. When the initial waste plastic sample melted, the first vapor production took an extra 30 minutes in each experiment. It was found that optimum and expected production captured is between 230-280°C. The maximum production temperature to give optimum yield margin rose to 300°C.

Once a sample finishes, the experiment shuts-down and was allowed to cool for 15 minutes. Subsequently the fuel oils produced were allowed to cool; the characterization was done using FT-IR spectrometer (Spectrum 100 Perkin-Elmer). The heat combustion properties of the fuels produced were compared using ASTM D240. Also the API gravity and Sulphur content analysis were carried out using the ASTM D4052 and 4053 respectively. Figure 2 presents some product samples from the pyrolysis process.

Physical analysis of products

The preliminary tests on the produced liquid fuel have shown that it is a mixture of various hydrocarbons having a range of carbon chain lengths for HDPE plastics to fuel C\textsubscript{3} to C\textsubscript{28}, LDPE plastics to fuel from C\textsubscript{3} to C\textsubscript{28}, PP plastics to fuel from C\textsubscript{3} to C\textsubscript{25} and mixed plastics to fuel from C\textsubscript{6} to C\textsubscript{18}. The produced fuel density is 0.916 (Table 1). In equivalent to obtaining the liquid hydrocarbon fuel we also received light gaseous hydrocarbon compounds (C\textsubscript{1}-C\textsubscript{4}) which resembles natural gas and table is showing individual plastic to fuel production yield %, light gas % and solid residue % (Table 2). Every individual waste plastic to fuel production experiment takes time of 5-6 hours and also input electricity for every individual experiment 14-15 kWh for 1 gallon production. Light gas wash by alkali wash and light gas analysis under consideration.

Table 1: Individual Waste Plastic to Fuel Production Yield Percentage.

| Name of Waste Plastic Fuel | Fuel Density g/ml | Specific Gravity | Fuel Color | Fuel Appearance |
|---------------------------|------------------|-----------------|------------|----------------|
| PP                        | 0.759            | 0.7582          | Light brown, light transparent | Wax and ash contain present |
| LDPE                      | 0.771            | 0.772           | Yellow, no transparent | Cloudy, wax and ash contain present |
| HDPE                      | 0.782            | 0.7812          | Yellow, light transparent | Wax and ash contain present |
| Mixed Plastic             | 0.916            | 0.915           | Light yellow, no transparent | Cloudy, wax and ash contain present |

Effect of reaction temperature

The pyrolysis process temperatures of liquid fuel oils from municipal waste plastics (PP, LDPE, HDPE and mixed plastic) are shown in Figure 3. It can be seen that the reaction temperatures of the plastic vary almost up to 300°C, and that these are the temperatures that the plastic types change from a solid state to liquid and vapor. The plastic types have different temperature ranges. PP has an average reaction temperature of 225°C. LDPE has an average reaction temperature of 210°C. HDPE has an average reaction temperature of 213°C. And mixed plastic has an average reaction temperature of 197°C. The plastic types used different
timeframes for their reaction, which is equally significant. PP and LDPE took 210 and 230 minutes to react respectively. While HDPE took 220 minutes to react. And the mixed plastic reaction time was 260 minutes. The differing temperatures that resulted in decomposition reactions provided hydrocarbons of different chain lengths. Pyrolysis of waste plastic grocery bags at temperatures of 420-440°C obtained a 74% yield of liquid product, referred to as plastic crude oil [2]. This study shows, when the temperature increases the yield of liquid products having low boiling points and gas products increases. The reason for this is during the oxidation degradation process, oxygen from air bonded to the organic compounds and this caused the formation of peroxides first. In this reaction series, the oxygen committed to the organic compounds at the end of the reactions produced the high liquid yield [12].

Table 2: Individual Waste Plastic to Fuel Production Yield Percentage.

| Name of Waste Plastic | Fuel Production Yield % | Light Gas (C₁-C₄) % | Solid Residue % |
|-----------------------|-------------------------|---------------------|-----------------|
| PP                    | 91.981                  | 2.073               | 5.944           |
| LDPE                  | 87.972                  | 5.806               | 6.221           |
| HDPE                  | 89.354                  | 5.345               | 5.299           |
| Mixed Plastic         | 85.331                  | 6.995               | 7.674           |

ASTM test results

Table 3 & 4 show some ASTM test results of the individual waste plastic to fuel. The waste plastic fuel oil fuel properties were carried out at PAX® Laboratory Limited, Port Harcourt, Rivers State, Nigeria. The results of the tests are presented, as shown in Table 3 & 4.

FT-IR (fourier transform infra-red spectroscopy) analysis

According to spectrum band peak different number of wave number emerged and in versus of peak wave number several kinds of functional radicals are obtained from the FT-IR (Fourier Transform Infra-red Spectroscopy). Notice that in some near about wave numbers is sited between in the range and same compounds are derived.

The comparative study of HDPE, LDPE, PP and Mixed Plastics fuel oil emerging that in different bands and wave number different functional groups and compound derived. In some cases the wave number is matched with one wave to another wave number, including compound identification is also found same compound or group. In HDPE, LDPE, PP and Mixed Plastics fuel oil common functional groups are CH\textsubscript{3}, C-CH\textsubscript{3}, CH\textsubscript{2}, -CH=CH-(cis) and -CH=CH-(trans). The spectrum feature of each individual fuel is uniquely identified. Although the wave number and spectrum band very near to each other so that derived compound functional group mostly common in the radical group. Noticeable that wave number of each individual fuel ascending to 700 cm\textsuperscript{-1} to 750 cm\textsuperscript{-1} and most probably compound is -CH=CH-(cis) and -CH=CH-(trans) groups. Besides common group available functional radical are also present in each fuel such as C-CH\textsubscript{3}, C=CH\textsubscript{2}, CH=CH\textsubscript{2}, =C-H and so on.

### Conclusion

The comparative study of densities found that the HDPE fuel density is 0.782g/ml, LDPE fuel density is 0.771g/ml, PP fuel density is 0.759g/ml and mixed plastic fuel density is 0.916g/ml. Similarly, the FTIR analysis of each individual fuel oil found that most of the functional group and compound are not unique from each other; they vary for different types of compounds. The comparative study of their chemical structures shows that in HDPE and LDPE similar -CH\textsubscript{2} and -CH\textsubscript{3} group appear in their polymer chain. However, in PP and mixed plastics, both structures contain aromatic benzene compound including methylene group, but PP contain a methyl (-CH\textsubscript{3}) group that is not found in mixed plastics. Likewise, mixed plastics contain plenty of methylene, benzene monomer in the long chain hydrocarbon.
From the findings above, it can then be concluded that:

a. The thermal conversion is an effective way of reducing municipal waste plastics.

b. Thermal conversion of municipal waste plastics yields economic benefits.

c. No environmental hazard(s) since the products formed contain negligible sulphur content.

Acknowledgment
None.

Conflict of Interest
None.
