Abstract

The true costs of high performance computing are currently dominated by software. Addressing these costs
requires shifting to high productivity languages such as Matlab. MatlabMPI is a Matlab implementation of the
Message Passing Interface (MPI) standard and allows any Matlab program to exploit multiple processors. Mat-
labMPI currently implements the basic six functions that are the core of the MPI point-to-point communications
standard. The key technical innovation of MatlabMPI is that it implements the widely used MPI “look and feel”
on top of standard Matlab file I/O, resulting in an extremely compact (∼250 lines of code) and “pure” implemen-
tation which runs anywhere Matlab runs, and on any heterogeneous combination of computers. The performance
has been tested on both shared and distributed memory parallel computers (e.g. Sun, SGI, HP, IBM, Linux and
MacOSX). MatlabMPI can match the bandwidth of C based MPI at large message sizes. A test image filtering
application using MatlabMPI achieved a speedup of ∼300 using 304 CPUs and ∼15% of the theoretical peak
(450 Gigaflops) on an IBM SP2 at the Maui High Performance Computing Center. In addition, this entire parallel
benchmark application was implemented in 70 software-lines-of-code, illustrating the high productivity of this
approach. MatlabMPI is available for download on the web (www.ll.mit.edu/MatlabMPI).

1 Introduction

MATLAB® is the dominant interpreted programming language for implementing numerical computations and is
widely used for algorithm development, simulation, data reduction, testing and system evaluation. The popularity
of Matlab is driven by the high productivity that is achieved by users because one line of Matlab code can typically
replace ten lines of C or Fortran code. Many Matlab programs can benefit from faster execution on a parallel
computer, but achieving this goal has been a significant challenge. There have been many previous attempts to
provide an efficient mechanism for running Matlab programs on parallel computers [2,3,4,5,6,7,8,9,10,11,12,13]. These efforts of have faced numerous challenges, such as limited support of Matlab functions and data structure
or reliance on machine specific 3rd party parallel libraries and language extensions.

In the world of parallel computing the Message Passing Interface (MPI) [11] is the de facto standard for imple-
menting programs on multiple processors. MPI defines C and Fortran language functions for doing point-to-point
communication in a parallel program. MPI has proven to be an effective model for implementing parallel programs
and is used by many of the worlds’ most demanding applications (weather modeling, weapons simulation, aircraft
design, and signal processing simulation).

ions, interpretations, conclusions and recommendations are those of the author and are not necessarily endorsed by the United States Govern-
ment

MATLAB is a registered trademark of The Mathworks, Inc.
MatlabMPI consists of a set of Matlab scripts that implements a subset of MPI and allows any Matlab program to be run on a parallel computer. The key innovation of MatlabMPI is that it implements the widely used MPI “look and feel” on top of standard Matlab file I/O, resulting in a “pure” Matlab implementation that is exceedingly small (∼250 lines of code). Thus, MatlabMPI will run on any combination of computers that Matlab supports.

The next section describes the implementation and functionality provided by MatlabMPI. Section three presents results on the bandwidth performance of the library from several parallel computers. Section four uses an image processing application to show the scaling performance that can be achieved using MatlabMPI. Section five presents our conclusions and plans for future work.

2 Implementation

The central innovation of MatlabMPI is its simplicity. MatlabMPI exploits Matlab’s built in file I/O capabilities, which allow any Matlab variable (matrices, arrays, structures, ...) to be written and read by Matlab running on any machine, and eliminates the need to write complicated buffer packing and unpacking routines which would require ∼100,000 lines of code to implement. The approach used in MatlabMPI is illustrated in Figure 1. The sender saves a Matlab variable to a data file and when the file is complete the sender touches a lock file. The receiver continuously checks for the existence of the lock file; when it exists the receiver reads in the data file and then deletes both the data file and the lock file. An example of a basic send and receive Matlab program is shown below.

```matlab
MPI_Init; % Initialize MPI.
comm = MPI_COMM_WORLD; % Create communicator.
comm_size = MPI_Comm_size(comm); % Get size.
my_rank = MPI_Comm_rank(comm); % Get rank.
source = 0; % Set source.
dest = 1; % Set destination.
tag = 1; % Set message tag.
if(comm_size == 2) % Check size.
    if (my_rank == source) % If source.
data = 1:10; % Create data.
MPI_Send(dest,tag,comm,data); % Send data.
    end
    if (my_rank == dest) % If destination.
data=MPI_Recv(source,tag,comm); % Receive data.
end
end
MPI_Finalize; % Finalize Matlab MPI.
exit; % Exit Matlab
```

The structure of the above program is very similar to MPI programs written in C or Fortran, but with the convenience of a high level language. The first part of the program sets up the MPI world; the second part differentiates the program according to rank and executes the communication; the third part closes down the MPI world and exits Matlab. If the above program were written in a matlab file called `SendReceive.m`, it would be executed by calling the following command from the Matlab prompt:

```matlab
eval( MPI_Run('SendReceive',2,machines) );
```

Where the `machines` argument can be any of the following forms:

```matlab
machines = {}; Run on the local host.
```
machines = {'machine1' 'machine2'}; Run on a multi processors.
machines = {'machine1:dir1' 'machine2:dir2'}; Run on a multi processors and communicate using dir1 and dir2, which must be visible to both machines.

The MPI_Run command launches a Matlab script on the specified machines with output redirected to a file. If the rank=0 process is being run on the local machine, MPI_Run returns a string containing the commands to initialize MatlabMPI, which allows MatlabMPI to be invoked deep inside of a Matlab program in a manner similar to fork-join model employed in OpenMP.

The SendReceive example illustrates the basic six MPI functions (plus MPI_Run) that have been implemented in MatlabMPI:

- **MPI_Run**: Runs a matlab script in parallel.
- **MPI_Init**: Initializes MPI.
- **MPI_Comm_size**: Gets the number of processors in a communicator.
- **MPI_Comm_rank**: Gets the rank of current processor within a communicator.
- **MPI_Send**: Sends a message to a processor (non-blocking).
- **MPI_Recv**: Receives message from a processor (blocking).
- **MPI_Finalize**: Finalizes MPI.

For convenience, three additional MPI functions have also been implemented along with two utility functions that provide important MatlabMPI functionality, but are outside the MPI specification:

- **MPI_Abort**: Function to kill all matlab jobs started by MatlabMPI.
- **MPI_Bcast**: Broadcast a message (blocking).
- **MPI_Probe**: Returns a list of all incoming messages.
- **MatMPI_Save_messages**: MatlabMPI function to prevent messages from being deleted (useful for debugging).
- **MatMPI_Delete_all**: MatlabMPI function to delete all files created by MatlabMPI.

MatlabMPI handles errors the same as Matlab, however running hundreds of copies does bring up some additional issues. If an error is encountered and the Matlab script has an “exit” statement then all the Matlab processes will die gracefully. If a Matlab job is waiting for a message that never arrives then it needs to be killed with the MPI_Abort command. In this situation, MatlabMPI can leave files which need to be cleaned up with the MatMPI_Delete_all command.

On shared memory systems, MatlabMPI only requires a single Matlab license since any user is allowed to launch many Matlab sessions. On a distributed memory system, MatlabMPI requires one Matlab license per machine. Because MatlabMPI uses file I/O for communication, there must also be a directory that is visible to every machine (this is usually also required in order to install Matlab). This directory defaults to the directory that the program is launched from.

## 3 Bandwidth

The vast majority of potential Matlab applications are “embarrassingly” parallel and require minimal performance out of MatlabMPI. These applications exploit coarse grain parallelism and communicate rarely (if at all). Never-the-less, measuring the communication performance is useful for determining which applications are most suitable for MatlabMPI.
MatlabMPI has been run on several Unix platforms. It has been benchmarked and compared to the performance of C MPI on the SGI Origin2000 at Boston University. These results indicate that for large messages (∼1 MByte) MatlabMPI is able to match the performance of C MPI (see Figure 2). For smaller messages, MatlabMPI is dominated by its latency (∼35 milliseconds), which is significantly larger than C MPI. These results have been reproduced using a SGI Origin2000 and a Hewlett Packard workstation cluster (connected with 100 Mbit ethernet) at Ohio State University (see Figure 3).

The above bandwidth results were all obtained using two processors engaging in bi-directional sends and receives. Such a test does a good job of testing the individual links on an a multi-processor system. To more broadly test the interconnect the send receive benchmark is run on an eight node (16 cpu) Linux cluster connected with Gigabit ethernet (see Figure 4). These results are shown for one and 16 cpus. MatlabMPI is able to maintain high bandwidth even when multiple processors are communicating by allowing each processor to have its own receive directory. By cross mounting all the disks in a cluster each node only sees the traffic directed to it, which allows communication contention to be kept to a minimum.

4 Scaling

To further test MatlabMPI a simple image filtering application was written. This application abstracts the key computations that are used in many of our DoD sensor processing applications (e.g. wide area Synthetic Aperture Radar). The application executed repeated 2D convolutions on a large image (1024 x 128,000 ∼2 GBytes). This application was run on a large shared memory parallel computer (the SGI Origin2000 at Boston University) and achieved speedups greater than 64 on 64 processors; showing the classic super-linear speedup (due to better cache usage) that comes from breaking a very large memory problem into many smaller problems (see Figure 5).

To further test the scalability, the image processing application was run with a constant load per processor (1024 x 1024 image per processor) on a large shared/distributed memory system (the IBM SP2 at the Maui High Performance Computing Center). In this test, the application achieved a speedup of ∼300 on 304 CPUs as well achieving ∼15% of the theoretical peak (450 Gigaflops) of the system (see Figure 6).

The ultimate goal of running Matlab on parallel computers is to increase programmer productivity and decrease the large software cost of using HPC systems. Figure 7 plots the software cost (measured in Software Lines of Code or SLOCs) as a function of the maximum achieved performance (measured in units of single processor peak) for the same image filtering application implemented using several different libraries and languages (VSIPL, MPI, OpenMP, using C++, C, and Matlab [14]). These data show that higher level languages require fewer lines to implement the same level of functionality. Obtaining increased peak performance (i.e. exploiting more parallelism) requires more lines of code. MatlabMPI is unique in that it achieves a high peak performance using a small number of lines of code.

5 Conclusions and Future Work

The use of file I/O as a parallel communication mechanism is not new and is now increasingly feasible with the availability of low cost high speed disks. The extreme example of this approach are the now popular Storage Area Networks (SAN), which combine high speed routers and disks to provide server solutions. Although using file I/O increases the latency of messages it normally will not effect the bandwidth. Furthermore, the use of file I/O has several additional functional advantages which make it easy to implement large buffer sizes, recordable messages, multi-casting, and one-sided messaging. Finally, the MatlabMPI approach is readily applied to any language (e.g. IDL, Python, and Perl).

MatlabMPI demonstrates that the standard approach to writing parallel programs in C and Fortran (i.e., using MPI) is also valid in Matlab. In addition, by using Matlab file I/O, it was possible to implement MatlabMPI entirely within the Matlab environment, making it instantly portable to all computers that Matlab runs on. Most potential
parallel Matlab applications are trivially parallel and don’t require high performance. Never-the-less, MatlabMPI can match C MPI performance on large messages. The simplicity and performance of MatlabMPI makes it a very reasonable choice for programmers that want to speed up their Matlab code on a parallel computer.

MatlabMPI provides the highest productivity parallel computing environment available. However, because it is a point-to-point messaging library, a significant amount of code must be added to any application in order to do basic parallel operations. In the test application presented here, the number of lines of Matlab code increased from 35 to 70. While a 70 line parallel program is extremely small, it represents a significant increase over the single processor case. Our future work will aim at creating higher level objects (e.g., distributed matrices) that will eliminate this parallel coding overhead (see Figure 8). The resulting “Parallel Matlab Toolbox” will be built on top of the MatlabMPI communication layer, and will allow a user to achieve good parallel performance without increasing the number lines of code.
