Differential Roles of Each Orexin Receptor Signaling in Obesity

**HIGHLIGHTS**

- Food intakes of Ox1r-deficient mice are similar between chow and high-fat food.
- Ox2r-deficient mice exhibit less energy expenditure when fed a high-fat diet.
- Orexin neurons are involved in the interactive effect of diet and exercise.
- Orexin-deficient mice have normal brown adipose tissue.

SUMMARY
Orexins are hypothalamic neuropeptides that regulate feeding, energy expenditure, and sleep. Although orexin-deficient mice are susceptible to obesity, little is known about the roles of the orexin receptors in long-term energy metabolism. Here, we performed the metabolic characterization of orexin receptor-deficient mice. Ox1r-deficient mice were resistant to diet-induced obesity, and their food intake was similar between chow and high-fat food. Ox2r-deficient mice exhibited less energy expenditure than wild-type mice when fed a high-fat diet. Neither Ox1r-deficient nor Ox2r-deficient mice showed body weight gain similar to orexin-deficient mice. Although the presence of a running wheel suppressed diet-induced obesity in wild-type mice, the effect was weaker in orexin neuron-ablated mice. Finally, we did not detect abnormalities in brown adipose tissues of orexin-deficient mice. Thus, each orexin receptor signaling has a unique role in energy metabolism, and orexin neurons are involved in the interactive effect of diet and exercise on body weight gain.

INTRODUCTION
A greater availability of energy-dense foods and reduced physical activity attribute to the current obesity pandemic in the modern society (Article et al., 2017). The C57BL/6 mouse has been used to study diet-induced obesity and to identify the regulatory effect of the gene-environment interaction on body weight (Collins et al., 2004; Funato et al., 2009). Easy access to a high-fat diet causes the mice to become overweight, which has provided insights into the central role of the hypothalamus in energy metabolism. The hypothalamus is composed of a variety of neural groups that are involved in mechanisms regulating feeding, energy expenditure, body temperature, and sleep/wakefulness.

Orexins (also known as hypocretins) are neuropeptides that are expressed in the lateral hypothalamic and were originally identified as factors that enhance feeding behavior (Sakurai et al., 1998). Subsequent research showed a wake-promoting effect of orexins (Chemelli et al., 1999; Sakurai, 2007) and orexin deficiency underlies the pathophysiology of narcolepsy (Nishino, 2007). Counterintuitive to the acute effect of orexin on promoting feeding, orexin deficiency or postnatal ablation of orexin neurons causes obesity in mice (Hara et al., 2005, 2001), suggesting that orexin functions as a negative regulator of energy metabolism. Consistent with these findings, human individuals with narcolepsy have been reported to exhibit a greater body mass index and a higher incidence of metabolic syndrome (Nishino, 2007). In contrast to orexin deficiency, orexin overexpression renders mice resistant to high-fat diet-induced obesity. Among the two receptors for orexin, type 1 (OX1R) and type 2 (OX2R), enhanced OX2R signaling is sufficient to induce resistance to diet-induced obesity in mice (Funato et al., 2009). Although acute or subacute effects of orexin receptor signaling on food intake and energy expenditure has been reported (Funato, 2015; Haynes et al., 2000; Rodgers et al., 2001), very little is known about the roles of the two orexin receptors, particularly their long-term effects on metabolism, partly because the metabolic phenotype of OX1R or OX2R loss-of-function mutant mice has not been reported.

Dual orexin receptor antagonists have been approved as a treatment for insomnia, and researchers are continuing to develop selective antagonists and agonists for each orexin receptor (Coleman et al., 2017; Janto et al., 2018; Nagahara et al., 2015). The development of several other drugs targeting orexin receptors is also underway. Thus, the metabolic characterization of mice deficient in OX1R or OX2R will provide indispensable information about the expected side effects of orexin receptor-targeting drugs and potential therapeutic targets.

Because both the ubiquitous access to a high-fat diet and reduced need for occupational physical activity are two major causes of the increased incidence of human obesity, we examined the effects of the
consumption of a high-fat diet and the presence of a running wheel in the home cage on body weight gain in C57BL/6 mice. Since orexin neurons have widespread connections to neural groups regulating energy metabolism and locomotion (Sakurai, 2007), we hypothesize that orexin neurons are involved in the body weight homeostasis through the integrative regulation of food intake and exercise.

In addition to the role of orexin in the central nervous system, orexin is required for the development of brown adipose tissue (BAT) (Sellayah et al., 2011; Sellayah and Sikder, 2014), which may affect metabolic phenotypes. However, we have never noticed gross abnormalities in the BAT of orexin-deficient mice, which prompted us to examine the BAT from orexin-deficient mice in detail.

Here, we report the different roles of OX1R and OX2R in energy metabolism and glucose metabolism through the metabolic characterization of orexin receptor-deficient mice. We also examined the role of orexin neurons in the interactive effect of diet and exercise on body weight gain. Consistent with our previous observation, we did not detect abnormalities in the morphology of or gene expression in the BAT of orexin-deficient mice.

**RESULTS**

**Body Weight Gain of Orexin-Deficient and Orexin Receptor-Deficient Mice**

To examine the differential roles of orexin receptors, we used Ox1r-deficient mice (Figure S1), Ox2r-deficient mice (Willie et al., 2003), and orexin-deficient mice (Chemelli et al., 1999). First, we examined the effect of an orexin receptor deficiency on the body weight gain of mice when fed a chow or a high-fat diet. At the age of 3 weeks, when mice were weaned, the body weight of orexin-deficient mice tended to be lower than that of wild-type mice, but the difference was not statistically significant (one-way ANOVA, p = 0.02; Tukey’s test, p = 0.075, Figure 1A). The body weight of 3-week-old Ox1r-deficient mice was greater than that of orexin-deficient mice and Ox2r-deficient mice (Tukey’s test, p = 0.002 for Ox1r-deficient mice, p = 0.031 for Ox2r-deficient mice, Figure 1A). After weaning, the 3-week-old mice were randomly assigned to regular chow or high-fat diet to determine how orexin signaling affects body weight gain over 6 weeks, which is consistent with the protocol described by Sellayah et al. (2011). Orexin-deficient mice fed the regular chow diet displayed a significantly greater body weight at 9 weeks old and greater weight gain over 6 weeks beginning at the age of 3 weeks than wild-type mice (two-way ANOVA, p < 0.001; Tukey’s test, p < 0.001, Figures 1B–1D). Both Ox1r-deficient and Ox2r-deficient mice showed greater weight gains than wild-type mice (Tukey’s test, p = 0.004 for Ox1r-deficient mice, p = 0.019 for Ox2r-deficient mice, Figure 1C).

The body weight of orexin-deficient mice fed a high-fat diet was greater than mice of the other genotypes (Tukey’s test, p < 0.001 for each group, Figures 1B, 1C, and 1E). Orexin-deficient mice fed a high-fat diet showed greater weight gain from 3 weeks old to 9 weeks old (Tukey’s test, p < 0.001 for each group, Figure 1C), consistent with previous reports (Funato et al., 2009; Hara et al., 2005; Sellayah et al., 2011). However, both 9-week-old Ox1r-deficient and Ox2r-deficient mice showed body weight and weight gain that were similar to that of wild-type mice (Figures 1B and 1C). Interestingly, high-fat diet feeding increased the body weight and weight gain of wild-type, orexin-deficient, and Ox2r-deficient mice at 9 weeks old compared with animals fed regular chow; the body weight and weight gain of Ox1r-deficient mice were similar, regardless of diet, suggesting that Ox1r-deficient mice were resistant to diet-induced obesity (Figures 1B and 1C).

At 9 weeks old, the body lengths of Ox2r-deficient mice were shorter than mice of other genotypes fed either regular chow or high-fat diet (two-way ANOVA, p < 0.001, Tukey’s test, p < 0.001 for between Ox2r-deficient and other groups, Figure 1F), which may be associated with reduced bone mass in Ox2r-deficient mice (Wei et al., 2014). Orexin-deficient mice presented a higher body mass index (BMI) than wild-type and Ox1r-deficient mice (p = 0.03 for wild-type; p < 0.001 for Ox1r-deficient, Figure 1G). Ox2r-deficient mice displayed a higher BMI than Ox1r-deficient mice (p = 0.049). Lower serum leptin levels were observed in wild-type mice fed a chow diet than orexin-deficient and Ox1r-deficient mice (two-way ANOVA, p < 0.001; Tukey’s test, p < 0.001 for orexin-deficient mice, p = 0.004 for Ox1r-deficient mice, Figure 1H), consistent with their body weights (Figure 1B). Lower serum leptin levels were observed in wild-type mice fed a high-fat diet that in orexin-deficient and Ox2r-deficient mice (p < 0.001 for orexin-deficient mice, p = 0.008 for Ox2r-deficient mice, Figure 1H), similar to their body weights and BMIs (Figures 1B and 1D). Ox1r-deficient mice fed a high-fat diet did not show any significant increase in BMI and leptin levels compared with mice of the same genotype fed a chow diet (Figures 1G and 1H).
Figure 1. Body Weight Gain of Orexin Receptor-Deficient Mice Fed Chow or High-Fat Diet (HFD)

(A) Body weights of wild-type (n = 33), orexin KO (n = 32), Ox1r KO (n = 23), and Ox2r KO mice (n = 22) at the age of 3 weeks. One-way ANOVA followed by Tukey’s test.

(B–E) Body weight measured at the age of 9 weeks (B) and weight gain from 3 weeks of age (C). Weight gain was measured weekly for chow (D) and HFD (E) mice groups. Wild-type (chow n = 12, HFD n = 21), orexin KO (chow n = 13, HFD n = 19), Ox1r KO (chow n = 10, HFD n = 13) and Ox2r KO mice (chow n = 9, HFD n = 13).

(F) At the age of 9 weeks, showing the body lengths of wild-type (chow n = 9, HFD n = 11), orexin KO (chow n = 9, HFD n = 8), Ox1r KO (chow n = 10, HFD n = 13), and Ox2r KO mice (chow n = 9, HFD n = 13).

(G) The BMI of wild-type at the age of 9 weeks. Wild-type (chow n = 13, HFD n = 11), orexin KO (chow n = 9, HFD n = 8), Ox1r KO (chow n = 10, HFD n = 13), and Ox2r KO mice (chow n = 9, HFD n = 13).

(H) The serum leptin levels in wild-type (chow n = 8, HFD n = 10), orexin KO (chow n = 8, HFD n = 10), Ox1r KO (chow n = 8, HFD n = 7), and Ox2r KO mice (chow n = 8, HFD n = 9).

Two-way ANOVA followed by Tukey’s test. *p < 0.05, **p < 0.01, ***p < 0.001 among genotypes. #p < 0.05, ##p < 0.01, ###p < 0.001 between diet groups. All data are presented as mean ± SEM. See also Figure S1.
Food Intake of Orexin-Deficient and Orexin Receptor-Deficient Mice

We examined the daily intake of chow and high-fat diet by mice of each genotype for 4 days at the ages of 11–13 weeks old. The daily chow intake of orexin-deficient mice was similar to that of wild-type mice (p = 0.317). Ox1r-deficient mice consumed more chow than wild-type mice (p = 0.001) and Ox2r-deficient mice (p < 0.001, Figure 2A). In contrast, the Ox1r-deficient mice consumed a significantly smaller amount of the high-fat diet than wild-type mice (p = 0.018, Figure 2A). When mice were fed a high-fat diet, wild-type and orexin-deficient mice consumed a larger amount of calories from food compared with mice fed a chow diet (Student’s t test with Bonferroni correction, p < 0.001 for wild-type, p = 0.002 for orexin-deficient mice).

When the food intake was compared between mice of the same genotype fed a chow diet and high-fat diet, wild-type and orexin-deficient mice consumed larger amounts of calories from the high-fat diet than the chow diet (two-tailed t test, p < 0.001 for wild-type, p = 0.006 for orexin-deficient mice). However, a significant difference in the energy intake of Ox1r-deficient and Ox2r-deficient mice was not observed between chow and the high-fat diet (p = 0.33 for Ox1r-deficient mice, p = 0.22 for Ox2r-deficient mice, Figure 2A).

Energy Expenditure of Orexin- or Orexin Receptor-Deficient Mice

We examined the energy expenditure of mice of each genotype fed chow or a high-fat diet. The energy expenditure of orexin-deficient mice fed a chow diet was similar to that of wild-type mice (p = 0.317). Ox1r-deficient mice consumed more chow than wild-type mice (p = 0.001) and Ox2r-deficient mice (p < 0.001, Figure 2A). In contrast, the Ox1r-deficient mice consumed a significantly smaller amount of the high-fat diet than wild-type mice (p = 0.018, Figure 2A). When mice were fed a high-fat diet, wild-type and orexin-deficient mice consumed a larger amount of calories from food compared with mice fed a chow diet (Student’s t test with Bonferroni correction, p < 0.001 for wild-type, p = 0.002 for orexin-deficient mice). When the food intake was compared between mice of the same genotype fed a chow diet and high-fat diet, wild-type and orexin-deficient mice consumed larger amounts of calories from the high-fat diet than the chow diet (two-tailed t test, p < 0.001 for wild-type, p = 0.006 for orexin-deficient mice). However, a significant difference in the energy intake of Ox1r-deficient and Ox2r-deficient mice was not observed between chow and the high-fat diet (p = 0.33 for Ox1r-deficient mice, p = 0.22 for Ox2r-deficient mice, Figure 2A).
diet compared with the chow diet (two-tailed t test with Bonferroni correction, p = 0.002), Ox2r-deficient mice showed decreased energy expenditure (p = 0.025). Both wild-type and orexin-deficient mice did not show any significant change in energy expenditure between regular chow and the high-fat diet (p = 0.07 for wild-type; p = 0.62 for orexin-deficient).

The respiratory quotient of orexin-deficient mice was lower than that of wild-type (two-way ANOVA, p < 0.001; Tukey’s test, p < 0.001), Ox1r-deficient (p = 0.005), and Ox2r-deficient mice (p < 0.001). Mice of all genotypes fed a high-fat diet showed a significant decrease in the respiratory quotient compared with mice fed regular chow (p < 0.001 for all groups, Figure 2C). The oxygen consumption of orexin-deficient mice fed a chow diet was similar to that of wild-type mice. Ox1r-deficient mice showed lower oxygen consumption than the other groups (p = 0.022 for Ox2r-deficient mice, Figure 2D). A significant difference in oxygen consumption was not observed among the different mouse strains after feeding on a high-fat diet (one-way ANOVA, p = 0.17). Wild-type, orexin-deficient, and Ox1r-deficient mice showed increased oxygen consumption on a high-fat diet than on a chow diet (two-tailed t test with Bonferroni correction, p < 0.001 for wild-type, p = 0.02 for orexin-deficient and p < 0.001 for Ox1r-deficient mice, Figure 2D). In contrast, Ox2r-deficient mice did not show any change in oxygen consumption between chow and a high-fat diet (p = 0.21 for Ox2r-deficient mice).

Glucose Metabolism in Orexin- or Orexin Receptor-Deficient Mice

Next, we examined glucose metabolism in mice deficient in orexin and its receptors. Nine-week-old orexin-deficient and orexin receptor-deficient mice fed a chow diet displayed a similar glucose level to wild-type mice (Figure 3A). A lower serum insulin level was observed in Ox2r-deficient mice than in Ox1r-deficient mice (One-way ANOVA, p = 0.02; Tukey’s test, p = 0.03, Figure 3B). After consumption of a high-fat diet, a higher glucose level was observed in orexin-deficient mice than in Ox2r-deficient mice (p = 0.041, Figure 3A). A higher insulin level was observed in orexin-deficient mice than in the other animal groups (p < 0.001 for all groups, Figure 3B). Although higher insulin levels were detected in orexin-deficient and Ox2r-deficient mice fed a high-fat diet than in animals fed a chow diet (two-tailed Student t test with Bonferroni correction, p < 0.001 for orexin-deficient, p = 0.004 for Ox2r-deficient mice), wild-type and Ox1r-deficient mice did not show significant differences in insulin levels between the regular chow and high-fat diet (Figure 3B).

Hypothalamic Gene Expression in Orexin- or Orexin Receptor-Deficient Mice

We examined how orexin deficiency and high-fat diet feeding alter the expression of genes related to food intake and energy metabolism in the adult hypothalamus. A two-way ANOVA identified suppressive effects of high-fat diet feeding on Agrp, Chh, Lepr, Mc4r, Mch, Ox1r, Ox2r, and Sim1 expression (Figure 4). Orexin-deficient mice showed reduced expression of Agrp, Ox1r, and Ox2r. Wild-type mice fed a high-fat diet
showed decreased expression of oxytocin compared with animals fed a chow diet. Chow diet-fed orexin-deficient mice expressed Pomc at higher levels than wild-type mice.

Reduced Anti-obesity Effect of Exercise in Orexin Neuron-Ablated Mice

Considering the rapid increase in the obese population in modern society due to the availability of cheap and high-caloric food and the decreased need for involuntary exercise, we examined the body weight gain of mice, which were group-housed in cages equipped with or without a running wheel and fed a normal chow or a high-fat diet from weaning to the age of 15 weeks. The presence of the running wheel suppressed the body weight gain of wild-type mice fed either regular chow or a high-fat diet (Figure 5A). Importantly, male mice fed a high-fat diet in a cage equipped with a running wheel gained less body weight than mice fed a chow diet, suggesting that the suppressive effect of a running wheel surpasses the obesogenic effect of the high-fat diet on wild-type mice. We used orexin-ataxin3 mice in which orexin neurons are ablated in the early postnatal period (Hara et al., 2001) to avoid possible developmental perturbation due to the loss of orexin signaling and the progressive effect of the loss of orexinergic neurons. Similar to wild-type mice, orexin-ataxin3 mice exhibited high-fat diet-induced obesity, and the presence of a running wheel suppressed this effect (Figure 5B). In contrast to wild-type mice, orexin neuron-ablated male mice fed a normal chow in a cage without a running wheel gained less body weight than mice fed a high-fat diet in a cage with a running wheel after the age of 10 weeks, when almost all orexin neurons were ablated (Hara et al., 2001). Based on this result, the suppressive effect of a running wheel is weaker in male orexin neuron-ablated mice. High-fat diet feeding increased body weight gain in female wild-type mice to a lesser extent than in male mice, consistent with the tight homeostatic regulation of body weight in female mice (Funato et al., 2009). A running wheel exerted a suppressive effect on weight gain in female mice fed a high-fat diet but not a chow diet (Figure 5C). Similarly, a similar suppressive effect of the running wheel was only observed in female orexin-neuron-ablated mice fed a high-fat diet (Figure 5D).

BAT of Orexin- and Orexin Receptor-Deficient Mice

Although many studies have focused on the central actions of orexin in energy metabolism (Funato, 2015; Sakurai and Mieda, 2011), Sellayah et al. reported the maldevelopment of the BAT in orexin-deficient mice as early as the neonatal period, which may lead mice to become overweight (Sellayah et al., 2011). However, the BAT of newborn orexin-deficient mice was indistinguishable from newborn wild-type mice, regardless of whether their mothers were heterozygous or homozygous orexin-deficient mice (Figure 6A). In contrast to the findings of the previous report (Sellayah et al., 2011), no difference in lipid droplet areas was observed between wild-type and orexin-deficient mice (Figures 6B and S2). Very low or undetectable levels of orexin receptors were expressed in the BAT of newborn wild-type mice (Figure 6C). No difference in UCP1 protein level in the BAT was observed between newborn wild-type and orexin-deficient mice (Figure 6D). Among the genes associated with the function and development of the BAT, such as Ucp1, Ucp2, Cox7a1, Cox8b, Pparγ, Pgc1α, Pgc1β, and Tpfam, only PGC1α was upregulated in the BAT of newborn orexin-deficient mice (two-tailed Student’s t test, p < 0.001.

Figure 4. Gene Expressions in Hypothalamus from Adult Orexin-Deficient Mice

The expression is presented relative to the mean of wild-type mice that fed the chow diet. Two-way ANOVA followed by Tukey’s test for each diet group. Ten mice per group. *p < 0.05, **p < 0.01, ***p < 0.001. Data are presented as mean ± SEM.
Figure 6E). This observation is opposite to the previous results (Sellayah et al., 2011). Thus, newborn orexin-deficient mice showed normal histological and molecular characteristics of the BAT. When adult mice were fed a chow diet, the BAT of orexin-deficient mice was similar to that of wild-type mice (Figure 6F). The BAT of orexin-deficient mice fed a high-fat diet displayed a decrease in the cell density compared with wild-type mice owing to a larger cell size that was enriched in lipid droplets (Figure 6G), which may have resulted from the obesity of orexin-deficient mice. Similar to newborn pups, adult BAT expressed a very low level of OX1R and almost undetectable level of OX2R (Figure 6H). UCP1 protein level in the BAT of adult orexin-deficient mice was lower than that of wild-type mice (Figure 6I). Two-way ANOVA detected a significant effect of high-fat diet feeding on increased Ucp1, Ucp2, Cox7a1, and Cox8b expression (Figure 6J). Orexin-deficient mice showed decreased Ucp2, Cox8b, and Pgc1β expression. Orexin-deficient mice fed a chow diet showed reduced Pgc1α expression.

DISCUSSION

Based on the findings from the current study, each orexin receptor has characteristic roles in energy metabolism and the diet-induced obesity of orexin-deficient mice is unlikely to be attributed to the lack of signaling from a single orexin receptor.
Figure 6. Histology and Gene Expression in the BAT of Orexin-Deficient Mice

(A) Representative images of BAT stained with hematoxylin and eosin from newborn wild-type (WT) and orexin-deficient (ORXKO) mice. Scale bars, 40 μm.

(B) Lipid droplet areas of the BAT in newborn WT and ORXKO mice (12 mice per group).

(C) Expression of orexin receptor genes in BAT from newborn wild-type mice (n = 7). The expressed is presented relative to the mean of orexin receptor expression in the brain.

(D) Western blot images of UCP1 and β-tubulin in BAT of newborn WT and ORXKO mice.

(E) Expression of genes related to the function and differentiation of BAT in newborn WT mice (n = 11) and ORXKO (n = 10). The expression is presented relative to the mean of newborn WT mice. **p < 0.01 obtained using t test with Bonferroni correction.

(F) Representative images of BAT stained with hematoxylin and eosin from adult mice. Scale bars, 40 μm.

(G) Adipocyte numbers of the BAT in adult male WT and ORXKO mice fed normal chow or on HFD (12 mice for each group).

(H) Expression of orexin receptor genes in BAT from adult wild-type mice fed normal chow (n = 6, 4–6 months old). The expression is presented relative to the mean orexin receptor expression in the brain. Ox2r was not detected in BAT.

(I) Representative western blot images of UCP1 and β-tubulin in BAT of chow-fed 14-week-old WT and ORXKO mice.
Orexin-deficient mice showed higher body weight and leptin levels at 9 weeks old and a greater weight gain from 3 weeks old to 9 weeks old than wild-type mice, regardless of diet. The current results confirmed previous reports that orexin-deficient mice are susceptible to diet-induced obesity (Hara et al., 2005; Sellayah et al., 2011). However, neither Ox1r-deficiency nor Ox2r-deficiency mimicked the strong diet-induced obesity observed in orexin-deficient mice, suggesting that deficiency in a single receptor signaling is not sufficient to render mice more susceptible to diet-induced obesity. Similar to the metabolic characteristics, neither Ox1r-deficient or Ox2r-deficient mice showed sleep abnormalities, such as frequent cataplexy-like behavior, observed in orexin-deficient mice (Chemelli et al., 1999; Hasegawa et al., 2014; Mahoney et al., 2019; Willie et al., 2003). Although orexin-deficient mice showed high-fat diet intake similar to wild-type mice, orexin-deficient mice showed lower energy expenditure than wild-type mice, which may be associated with lower expression of Ucp2, Cox8b, and Pgc1α in the BAT. Orexin-deficient mice also showed lower UCP1 protein in the BAT despite no change in Ucp1 mRNA, suggesting fast UCP1 degradation in orexin-deficient mice. Thus, insufficient energy usage may underlie the higher susceptibility of orexin-deficient mice to diet-induced obesity. Although we did not examine in this study, another possible target of the orexin system is creatine-driven futile cycling in beige fat, which is largely independent of UCP1 (Kazak et al., 2015).

Our data suggest an inverse relationship between the body weight gain and energy expenditure in wild-type and orexin-deficient mice. Orexin-deficient mice gained 4 g of body weight as shown in Figure 1C and decreased energy expenditure by around 20 cal/kg/BW/m (Figure 2B) in 6 weeks when compared with the wild-type mice. The body weight gain can be translated into fat mass growth of 4 g (36 kcal), equivalent to the cumulative sum of the energy expenditure reduction over 6 weeks. However, the change in energy expenditure value was not statistically significant between the wild-type and orexin-deficient mice. This could be due to the larger variability in energy expenditure than the body weight that may lead to the lower statistical power, thus failing to reach statistical significance. In addition, although orexin was originally identified as an orexigenic peptide (Sakurai et al., 1998), the effect is acute and recognized during the light phase. Long-term injection of orexin did not change food intake (Yamanaka et al., 1999), and dual orexin receptor agonist did not alter food intake (Tsuneki et al., 2016). Consistently, we observed similar food intake between wild-type and orexin-deficient mice.

Ox1r-deficient mice showed greater body weight and higher leptin levels at 9 weeks old and a greater weight gain from 3 weeks old to 9 weeks old than wild-type mice when fed a chow diet, which mimics the metabolic phenotype of orexin-deficient mice fed a chow diet. When Ox1r-deficient mice were fed a high-fat diet, however, the body weight and leptin levels at 9 weeks old and weight gain from 3 weeks old to 9 weeks old were similar to that of wild-type mice and significantly lower than that of orexin-deficient mice. Importantly, high-fat diet feeding did not increase the body weight and leptin levels of Ox1r-deficient mice. Thus, Ox1r-deficient mice were characterized by resistance to diet-induced obesity and a higher body weight set point (Figure 7). The tight regulation of energy balance in Ox1r-deficient mice underlies the stable caloric intake between chow and high-fat diet feeding, and the increased energy expenditure when fed a high-fat diet compared with regular chow. In addition, the loss of OX1R signaling may disturb reward-related high-fat diet intake that is observed in wild-type C57BL/6 mice (Johnson and Kenny, 2010). The lack of increase in the intake of the high-fat diet by Ox1r-deficient mice suggests a disturbance in the reward behavior (Sakurai, 2014), consistent with the effect of OX1R on dopaminergic neurons (Moorman and Aston-Jones, 2010; Prince et al., 2015), and the suppression of motivation for high-fat diet feeding by an OX1R antagonist (Alcaraz-Iborra et al., 2014; Borgland et al., 2009; Nair et al., 2008; Sharf et al., 2010; Steiner et al., 2013; Valdivia et al., 2014), but not by an OX2R antagonist (Piccoli et al., 2012).

Ox2r-deficient mice displayed greater weight gain from 3 weeks old to 9 weeks old than wild-type mice when fed a chow diet, similar to orexin-deficient mice and Ox1r-deficient mice. When fed a high-fat diet, Ox2r-deficient mice showed a higher leptin level than wild-type mice and a similar body weight to wild-type mice, which may partially be explained by the shorter body length of Ox2r-deficient mice. In contrast to Ox1r-deficient mice, high-fat diet feeding increased the body weight and leptin levels of
Ox2r-deficient mice. Ox2r-deficient mice were characterized by reduced energy expenditure when fed a high-fat diet compared with regular chow (Figure 6). Thus, OX2R signaling is required for the proper response to a high-fat diet by increasing energy expenditure and is consistent with the role of OX2R signaling as a negative regulator of the energy balance, based on an orexin overexpression study (Funato et al., 2009).

High-fat diet feeding increased serum insulin levels in orexin-deficient mice and Ox2r-deficient mice. Since an increased serum insulin level is an early indicator of a deterioration of glucose metabolism, the disturbed glucose metabolism in orexin-deficient mice and Ox2r-deficient mice is largely consistent with the body mass index and leptin levels. Thus, although orexin receptors are expressed in the pancreatic islet (Adeghate et al., 2010; Kirchgessner and Liu, 1999; Nowak et al., 2005), the absence of the orexin receptors did not exert an apparent effect on glucose metabolism.

The differential effects of OX1R- and OX2R-signaling may be attributed to the biased expression of each orexin receptor in neuronal groups and also to different intracellular signaling. We recently showed that high-fat diet-fed orexin-overexpression mice exhibited increased phosphorylation level of S6 and S6K, indicators of the mTORC1 pathway activity, compared with high-fat-fed wild-type mice (Wang et al., 2014).
Considering that orexin-overexpression mice are resistance to diet-induced obesity via OX2R signaling (Funato et al., 2009), the OX2R-mTORC1 pathway may be involved in energy expenditure regulation. Since mTORC1 plays important roles in nutrient sensing, glucose homeostasis, and energy metabolism (Saxton and Sabatini, 2017), mTORC1 may expand the diversity in the orexin receptor downstream effectors, in addition to the well-known downstream cascade involving effectors like PKA and PKC (Wang et al., 2018).

As shown in the current study, the presence of a running wheel in the home cage suppressed high-fat diet-induced weight gain in both male and female mice. The suppressing effect of a running wheel exceeded the obesogenic effect of the consumption of a high-fat diet in male wild-type mice. In contrast, the presence of the running wheel exerted a weaker suppressive effect on male orexin neuron-ablated mice, as the body weight of mice fed a high-fat diet in a cage equipped with a running wheel group was greater than that of mice fed a chow diet in a cage without a running wheel. This finding implies that orexin neurons are involved in the homeostatic body weight regulation through a coordinated modulation of high-fat diet intake and exercise.

Although Sellayah et al. claimed that peripheral orexin functions in the development and maintenance of normal BAT (Sellayah et al., 2011; Sellayah and Sikder, 2014), we failed to reproduce their main findings, such as low levels of intracellular lipid droplet accumulation and decreased expression of genes related to mitochondrial energy production, in the BAT of neonatal and adult mice. Since the authors did not show diet-induced obesity in wild-type C57BL/6 mice (Figure 1A in Sellayah et al., 2011), despite numerous reports (Collins et al., 2004; Funato et al., 2009) including the current study produced the results (Figure 1), we suspect that their study had some technical issues. Thus, the current results do not support the direct effect of orexin on BAT development but, instead, the role of orexin signaling in the regulation of BAT via sympathetic system. Importantly, Martin et al. showed that the ventromedial hypothalamus functions as an upstream of orexin neurons, which in turn activates BAT via VGlut2-dependent sympathetic pathway (Martins et al., 2016). The raphe pallidus is the important relay that receives orexin input and promotes thermogenesis of the BAT (Tupone et al., 2011).

Another finding reported in the present study is the short body length of Ox2r-deficient mice, which may be associated with the low body mass of Ox2r-deficient mice (Wei et al., 2014). Further studies are necessary to explain why orexin-deficient mice have normal body length despite the loss of OX2R signaling. One hypothesis is that the suppressive effect of the loss of OX2R signaling on body length growth may depend on OX1R signaling.

In conclusion, OX1R and OX2R signaling are involved in different aspects of energy metabolism and deficiency in both receptors may be required to develop the diet-induced obesity observed in orexin-deficient mice. We also examined the role of orexin neurons in the effect of the interaction between diet and exercise on body weight gain. Finally, we did not detect abnormalities in the morphology of or gene expression in the BAT of orexin-deficient mice. Thus, we postulate that the central action of orexin underlies the susceptibility of orexin-deficient mice to obesity and that the BAT develops normally even in the absence of orexin. This study strongly suggests that orexin receptors are attractive drug targets as treatment for obesity by reducing reward value of energy-dense palatable food and increasing energy expenditure. Notably, orexin neurons functions as an integrative center to shape behaviors.

**Limitations of the Study**

In our study, we demonstrate the differential roles of each orexin receptor in food intake and energy expenditure using young adult mice. As aging affects energy and glucose metabolism, the metabolic phenotypes of orexin receptor-deficient mice may vary depending on the age. In previous study, for example, we showed lower insulin level in OX1R-deficient mice in older mice (Funato et al., 2009).

Since OX1R and OX2R are expressed in the brain with some anatomical differences (Mieda and Sakurai, 2011), future work is necessary to identify brain regions or neuronal groups that are responsible for the differential metabolic effect of each orexin receptor. In addition, as orexin receptors are expressed in the peripheral tissues (Xu et al., 2013), the peripheral action of orexin may exert its effect through the maintenance of the intestinal barrier (Tunisi et al., 2019).

**METHODS**

All methods can be found in the accompanying Transparent Methods supplemental file.

Images of hematoxylin-eosin-stained sections (left column) of newborn wild-type mice were converted to grayscale (middle column) and further thresholded with a size filter (right column). The upper and lower rows show images of tissues containing lipid droplet areas of 39% and 12%, respectively. Scale bars: 50 μm.
Transparent Methods

Animals
Male C57BL/6J mice (CLEA Japan, Tokyo, Japan) were used in this study. Mice were provided food and water ad libitum, maintained on a 12-hour light/dark cycle and housed under controlled temperature and humidity conditions. All procedures were conducted in accordance with the Guidelines for Animal Experiments of University of Tsukuba and Toho University, and were approved by the Institutional Animal Care and Use Committee of University of Tsukuba (Approved protocol ID # 150194) and Toho University (Approved protocol ID # 18-42-349). We used orexin-deficient mice (Chemelli et al., 1999), Ox2r-deficient mice (Willie et al., 2003) and orexin-ataxin transgenic mice (Hara et al., 2001). Ox1r-deficient mice are described below.

Production of Ox1r-deficient mice
A genomic fragment containing exons 5 (244 bp) and exon 6 (116 bp) of the Ox1r gene was isolated from a C57BL/6 mouse genomic BAC clone from a RP23 mouse genomic BAC library (Advanced GenoTEchs Co) to generate Ox1r-deficient mice. Exons 5 and 6 encode the region from the third transmembrane domain through the fifth transmembrane domain. A 1.7-kb fragment of the FRT-PGK-gb2-neo-FRT-loxP cassette (Gene Bridges) was inserted after exon 6. The targeting vector also contains a loxP sequence before exon 5. The targeting vector was linearized and electroporated into the C57BL/6N ES cell line RENKA. Correctly targeted clones were injected into eight-cell stage ICR mouse embryos, which were cultured to produce blastocysts and then transferred to pseudopregnant ICR females. The resulting chimeric male mice were crossed with female C57BL/6N mice to establish the Ox1rflox-neo/+ line. Ox1rflox-neo/+ mice were crossed with Actb-Flp knock-in mice to remove the neomycin resistance gene with the Flp-FRT system. Ox1rflox-neo/+ mice were further crossed with Ayu1-Cre mice to establish Ox1r-deficient mice (See Figure S1).

Mouse model of diet-induced obesity
C57BL/6 mice were fed a high-fat diet (D12492; Research Diet) starting after weaning at 3-4 weeks of age. The low-fat diet or normal chow (MF; Oriental Yeast) provided 3.6 kcal/g (61% carbohydrate, 26% protein, and 13% fat), whereas the high-fat diet provided 5.2 kcal/g (20% carbohydrate, 20% protein, and 60% fat). After 9 weeks of being fed the high-fat diet, mice were sacrificed at ZT11. Some cages were equipped with a running wheel (#ENV-044, Med
Measurement of daily food intake
The mice were individually housed and fed powdered chow (MF; Oriental Yeast) or high-fat diet (D12492; Research Diet) in a small food jar. After one week of habituation to the powdered food, the amount of food intake was measured every 24 hours for four consecutive days.

Physical parameters
Mice were extended to their full length by the same experimenter, and the snout-to-anus distance was determined to measure the body length. The BMI was calculated as weight in grams divided by the square of the height in centimeters.

Blood analysis
Blood glucose levels were measured in blood from the tail using Glutest kits (Sanwa Kagaku). Blood was collected from the tail vein or orbital sinus of anesthetized mice to measure insulin and leptin levels. The blood was centrifuged, and then the serum was stored at -80°C until use. Samples were analyzed using Mouse Insulin ELISA kits and Mouse Leptin ELISA kits (Morinaga Institute of Biological Science, Yokohama, Japan).

Indirect calorimetry
Indirect calorimetry was performed using an ARCO system (ARCO, Japan). For genetic studies, 10- to 12-week-old animals were individually housed in calorimeter chambers for more than 3 days for acclimatization and then data were collected for 5-6 days. The mice were fed chow or a high-fat diet from the age of 3 weeks. Raw energy expenditure was calculated as (3.815 + 1.2323 x respiratory quotient (RQ) x oxygen consumption. RQ was calculated as the ratio of carbon dioxide production to oxygen consumption.

Tissue preparation
Mice were sacrificed via cervical dislocation under deep anesthesia with sodium pentobarbital (50 mg/kg body weight). Then, the brain was rapidly removed and the medial hypothalamus was dissected on ice based on the following boundaries: rostral, the optic chiasm; caudal, the mammillary bodies; 1 mm bilateral from the midline; and 1.5 mm dorsal of the ventral surface. This dissected tissue included the arcuate nucleus, ventromedial hypothalamic nucleus,
dorsomedial hypothalamic nucleus, paraventricular hypothalamic nucleus, anterior hypothalamic area, and the medial half of the lateral hypothalamic area.

**Quantitative RT-PCR**

Total RNA was isolated using the RNeasy Lipid Tissue Mini kit (Qiagen, Chatsworth, CA) and used for cDNA synthesis with oligo dT primers and a PrimeScript reverse transcriptase kit (TaKaRa). Real-time quantitative PCR reactions were performed with the ViiA7 Real-Time PCR System (Thermo Fisher) using SYBR GREEN PreMix Ex Taq (TaKaRa). The following PCR primers were used: Agrp forward, 5'-TCCCAGAGTTCCCAGGTCTA-3; Agrp reverse, 5'-GCCAAAGCTTCTGCCTTCTTCT-3; Avp forward, 5'-AGGATGCTCAACACTACGCTCTCT-3; Avp reverse, 5'-ACTGTCTCAGCTCCATGTCAAG-3; Crh forward, 5'-GAAAGGGAAAAGGCAAAAGA-3; Crh reverse, 5'-GGCTGGGCGCTCTCTTCTC-3; Gapdh forward, 5'-AGAACATCATCCCTGCATCA-3; Gapdh reverse, 5'-CACATTGGGGTAGGAACAC-3; Ghrhr forward, 5'-CTCTTTGTGATCCTCATCAC-3; Ghrhr reverse, 5'-AGTTCCTGTAGTGGTGTTGAA-3; Mc4r forward, 5'-GCCAGGTCAACTCAGAAGG-3; Mc4r reverse, 5'-ATGAAGCAGACGAGCTATGG-3; Mch forward, 5'-TGCTGACGACACAGGAAA-3; Mch reverse, 5'-GCAACATGGTGCAGACTCT-3; Npy forward, 5'-TACTCCGCTCTGCGACTA-3; Npy reverse, 5'-TCACCAGGAAGGTCTT-3; Orexin forward, 5'-GGGTATTTGGATAGTTC-3; Orexin reverse, 5'-CCCAGGAGAAGAACTACCT-3; Oxytocin forward, 5'-CTCCGAGAAGGCACTCAG-3; Pacap forward, 5'-CTATGGCATTATGGGTGCTAAGG-3; Pacap reverse, 5'-GACCTGAGAAGCTTCTTTAG-3; Pomc forward, 5'-ATAGTGGCTGCTGTCC-3; Pomc reverse, 5'-TTTTCAGTCGGGCTGTTT-3; Sim1 forward, 5'-CTCCCATCCACAGAATCCAC-3; Sim1 reverse, 5'-TGATAGTGGTCGCGGTA-3; Somatostatin forward, 5'-CTCTGCATCTAGCTGGCTT-3; Somatostatin reverse, 5'-AATGGTAGGTCGTTGCT-3; Trh forward, 5'-GAAGGTGCTGACTTCTGAC-3; Trh reverse, 5'-ATCTAAGGCAGCAACACGGT-3.

A relative quantification method was employed to quantify the expression of the target mRNAs by calculating the ratio between the amount of the target mRNA and a reference mRNA within the same sample, according to the manufacturer’s protocol. The reactions were performed in duplicate and the results were averaged. The average levels of the *glyceraldehyde-3-phosphate dehydrogenase (GAPDH)* mRNA were used for normalization.
Body weight gain of mice fed a high-fat diet in a cage equipped with a running wheel

Male and female wild-type and orexin neuron-ablated mice were randomly assigned to either chow or a high-fat diet (D12451; Research Diet) and housed in a cage equipped with or without a running wheel (ENF-044; Med Associates). Mice were group-housed after the ages of 6 weeks. Body weight was measured weekly from the ages of 4 weeks to 15 weeks.

Histological assessment of brown adipose tissue (BAT)

Mice were deeply anesthetized with isoflurane and transcardially perfused with phosphate-buffered saline (PBS) followed by 4% paraformaldehyde in PBS. The BAT was postfixed with 4% PFA at 4°C overnight. The fixed tissues were embedded in paraffin. The BAT was sectioned at a thickness of 8 μm and processed for hematoxylin-eosin staining. Images of the stained sections were acquired using LSM700 with Plan-Apochromat 20x/0.8 M27 (Zeiss). Images were converted to 8-bit grayscale and then thresholded with a size filter using ImageJ software (National Institutes of Health) to determine the lipid droplet area (See Figure S2). We delineated the cell borders of all adipocytes in each image (450 μm x 350 μm) with a dark pen and then counted the number of adipocytes. The adipocyte number was recalculated as the number per square millimeter. The histological assessment was performed by an investigator who was blinded to the animal information.

Immunoblotting

A rabbit monoclonal antibody against UCP1 (clone D9D6X, #14670, Cell Signaling Technologies) was used as a primary antibody. Mice were sacrificed via cervical dislocation under deep anesthesia with sodium pentobarbital (50 mg/kg body weight). Then, the BAT was rapidly removed, frozen in liquid nitrogen and stored at -80°C until use. The BAT was homogenized using a rotor-stator homogenizer (Polytron) in ice-cold lysis buffer (20 mM HEPES pH7.5, 100 mM NaCl, 10 mM Na4P2O7, 1.5% Triton-X100, 15 mM NaF, 1X PhosSTOP (Roche), 5 mM EDTA, 1X Protease Inhibitor (Roche)), and then centrifuged at 13,000g at 4 °C. The supernatants were separated by SDS-PAGE and transferred on PVDF membrane. Blots were subsequently washed in PBS plus 0.1 % Tween-20 (PBS-T) and incubated overnight at -4°C with primary antibody (1:1000) in PBS-T with 5% bovine serum albumin. The blot was then washed and incubated with horseradish peroxidase-conjugated, donkey anti-rabbit IgG (Jackson ImmunoReserarch; 1:5,000 dilution in 5% skim milk and PBS-T). After washed, the blot was
The chemiluminescence signaling was detected using FUSION Solo 6S.EDGE (Vilber-Lourmat).

Statistics
Sample sizes were determined using R software based on averages and standard deviations that were obtained from small-scale experiments or from our previous data (Funato et al., 2009). No method of randomization was used in any of the experiments. The experimenters were blinded to genotypes and treatment assignments. Statistical analyses were performed using SPSS Statistics 22 software (IBM). We first performed a two-way ANOVA using diet and genotype as the two independent variables to assess the significance of differences in most parameters, such as body weights and leptin levels. When a significant interaction between diet and genotype was found, we performed an ANOVA on the results from each diet group followed by Tukey’s test. When the two-way ANOVA detected significant effect of the genotype, we further performed a Tukey’s test of the genotype. We performed two-tailed Students T-test with Bonferroni correction to compare parameters from mice of the same genotype between regular chow and a high-fat diet. $P < 0.05$ was considered statistically significant. All data are presented as mean ± SEM.
