Abstract. In this paper, we present convex hull formulations for a mixed-integer, multilinear term/function (MIMF) that features products of multiple continuous and binary variables. We develop two equivalent convex relaxations of an MIMF and study their polyhedral properties in their corresponding higher-dimensional spaces. We numerically observe that the proposed formulations consistently perform better than state-of-the-art relaxation approaches.

Introduction

Last few decades has seen tremendous advances in developing efficient convex relaxations of multilinear functions to solve factorable, non-convex Mixed-Integer Nonlinear Programs (MINLPs) to global optimality [1]. State-of-the-art spatial B&B-based solvers, such as Baron and SCIP, heavily rely on the tightness of relaxations to efficiently converge to global optimality. Nevertheless, global optimization for large-scale MINLPs is still a challenge. Particularly, there has been scarce literature which focuses on developing relaxations for Mixed-Integer Multilinear Functions (MIMFs). Thus, the focus of this article is on developing tight, term-wise polyhedral relaxations for an MIMF.

MIMF is a multilinear function that features products of multiple continuous and binary variables. MINLPs with MIMFs appear in several important applications [9, 4, 2, 13]. A hierarchy of reformulation-based relaxations can be applied to generate an extended linear program, however without guarantees of capturing the convex hull in the mixed-integer space [15, 8]. There has been a line of work that utilizes perspective functions and disjunctive formulations to develop tight and tractable relaxations for convex MINLPs, involving on-off variables [3, 6, 7]. In this article, we leverage theses ideas and develop tractable polyhedral relaxations for nonconvex MIMFs. We now formally define MIMFs.

Notation

Boldface fonts denote vectors. Given two vectors $a$ and $b$, $a^T b$ denotes the dot product of the two vectors. $\mathbf{0}$ and $\mathbf{1}$ are used to denote vectors of zeros and ones, respectively. The operation $| \cdot |$ denotes the cardinality of a set. $\text{conv}(A)$ denotes the convex hull of set $A$ containing points in the Euclidean space.

Given this notation, an MIMF, $\varphi(x, z) : [\ell, u] \times \{0, 1\}^{|J|} \rightarrow \mathbb{R}$, is formally defined as

$$\varphi(x, z) = \prod_{i \in I} x_i \prod_{j \in J} z_j,$$

where $I$ and $J$ denote the index set for the vector of continuous and binary variables, respectively, and $[\ell, u] = \{x \in \mathbb{R}^{|I|} : \ell \leq x \leq u\}$. For ease of exposition, we also let $\varphi_x(x) = \prod_{i \in I} x_i$ and $\varphi_z(z) = \prod_{j \in J} z_j$. We then let $\mathcal{K}$, indexed by $k$, denote the set of $2^{|I|}$ extreme points of $x$ as defined by $[\ell, u]$. The notation $\xi_k$ is used to denote extreme point $k \in \mathcal{K}$. Given $\varphi(x, z) = \varphi_x(x) \cdot \varphi_z(z)$, the primary goal of this paper is...
to develop tight polyhedral relaxations of the graph of such a function, given by the set \( X = \{(x, z, \varphi) \in [\ell, u] \times [0, 1]^{|J|} \times \mathbb{R} : \varphi = \varphi(x, z)\} \).

**McCormick Relaxations:** In the special case of continuous bilinear function, \( \varphi_z(x) = x_1x_2 \), McCormick [10] developed a widely used tight relaxation. Given set \( X^B = \{(x_1, x_2, \varphi) \in [\ell_1, u_1] \times [\ell_2, u_2] \times \mathbb{R} : \varphi = x_1x_2\} \), the McCormick relaxation is given by

\[
\langle x_1, x_2, \varphi \rangle^MC := \text{conv}(X^B) = \left\{ (x_1, x_2, \varphi) \in [\ell_1, u_1] \times [\ell_2, u_2] \times \mathbb{R} : \begin{array}{l}
\varphi \geq u_2x_1 + x_1u_2 - u_1u_2, \\
\varphi \geq \ell_2x_1 + \ell_1x_2 - \ell_1\ell_2,
\end{array} \right\}. 
\]

(1)

It is known that Eq. (1) describes the convex hull of \( X^B \) (see [10]). For a multilinear function, \( \varphi_z(x) = \prod_{i \in J} x_i \), standard global optimization methods apply recursive McCormick relaxations sequentially on bilinear terms, which do not necessarily capture the convex hull of the graph of \( \varphi_z(x) \).

In the special case of multilinear function, \( \varphi_z(x) = \prod_{i \in J} x_i \), it’s exact linear reformulation is given by

\[
\left\{ (\tilde{z}, \tilde{\varphi}) \in [0, 1]^{\sum_{i \in J} 1} : \tilde{\varphi} = \varphi_z(x) \right\}.
\]

(2)

**λ-Formulation:** The strongest relaxation of the set \( X_z = \{(x, \varphi) \in [\ell, u] \times \mathbb{R} : \varphi = \varphi(x)\} \) based on the extreme-point characterization. More formally, [14] shows that conv(\( X_z \)) is defined by

\[
\text{conv}(X_z) = \text{Proj}_{\varphi_z} \left( (\varphi_x(x), \varphi^d) \right),
\]

(3)

\[
\langle \varphi_x(x), \varphi^d \rangle^d = \left\{ (x, \varphi, \lambda) \in [\ell, u] \times \mathbb{R} \times \Delta_{|K|} : x = \sum_{i \in K} \lambda_i \xi_i, \varphi = \sum_{i \in K} \lambda_i \varphi(x_i) \right\}
\]

(4)

\( \Delta_{|K|} \) is a \(|K|\)-dimensional 0-1 simplex. This formulation can also be applied to an MIMF (\( \varphi(x, z) \)) with \( 2^{|J|+|K|} \) extreme points. However, the major drawback of using this formulation for MIMF is that \(|J| \) grows exponentially with the number terms in the MIMF. Thus, it would be useful to derive more compact relaxations. In summary, the literature on tractable formulations for an MIMF, \( \varphi(x, z) \), is scarce, thus motivating the study in this article.

**Disjunctive formulation \( \tilde{X}^d \)**

We now present \( \tilde{X}^d \), a relaxation of \( X \) based on an extreme-point characterization that has at most \( O(2^{|J|}) \) \( \lambda \) variables. This relaxation is obtained as a disjunctive union of sets \( X^0 \) and \( X^1 \), where

\[
X^0 = \left\{ (x, \varphi, \lambda, z, \tilde{\varphi}) \in [\ell, u] \times \mathbb{R} \times [0, 1]^{\sum_{i \in K} 1} : \begin{array}{l}
\varphi = 0, \\
\tilde{\varphi} = 0, \\
z \leq |J| - 1, \\
\lambda = 0
\end{array} \right\}
\]

(5)

\[
X^1 = \left\{ (x, \varphi, \lambda, z, \tilde{\varphi}) \in \langle \varphi_x(x), \varphi^d \rangle^d \times [0, 1]^{\sum_{i \in K} 1} : z = 1, \tilde{\varphi} = 1 \right\}
\]

(6)

We now define the set \( \tilde{X} \) and show that \( \tilde{X} \) is a formulation for conv(\( X^0 \cup X^1 \)).
Let us now present the proof. Given that 

\[ \zeta \cdot 1 \leq z, \quad \zeta \geq 1^T z - |\mathcal{F}| + 1, \]

the inequalities of Eq. (9) are then derived through linear algebra on Eqs. (10) and (11). Similarly, it is easy to verify that the above point \( p^* \) is the projection of \( \tilde{F} \) onto the space of original variables. We conjecture that the projection of \( \tilde{X} \) onto the space of original variables is indeed \( \text{conv}(X) \), but this remains an open question.

**Disjunctive formulation \( \tilde{X}^{rmc} \)**

We now present \( \tilde{X}^{rmc} \), a relaxation of set \( X \) based on recursive McCormick relaxations on bilinear functions, typically employed in state-of-the-art global solvers. Let

\[ \psi(x, z) = \left( x_{1,1} x_{2,1} \ldots x_{|\mathcal{F}|,1} \right) \prod_{j \in \mathcal{J}} x_j \]

\[ \tilde{X} = \begin{cases} (x, \varphi, \lambda, z, \tilde{z}) \in [\ell, u] \times [0, 1]^{X_i + |\mathcal{J}| + 1}: \\
\quad \tilde{z} \cdot 1 \leq z, \quad \tilde{z} \geq 1^T z - |\mathcal{J}| + 1, \\
\quad 1^T \lambda = \varphi, \quad \varphi = \sum_{k \in K} \lambda_k \varphi_k(\xi_k), \\
\quad \sum_{k \in K} \lambda_k \xi_k + (1 - \tilde{z}) \leq x \leq \sum_{k \in K} \lambda_k \xi_k + u(1 - \tilde{z}) \end{cases} \]
By applying recursive McCormick relaxations, \( \tilde{\varphi}(x) \) can be replaced by a lifted variable \( \tilde{\varphi} \), thus reducing (12) to \( \varphi(x, z) = \tilde{\varphi} \cdot x_{\mathcal{J}} \prod_{j \in \mathcal{I}} z_j \). These recursive relaxations do not necessarily capture the convex hull of the MIMF in the extended space. However, observing the special structure of \( \tilde{\varphi} \cdot x_{\mathcal{J}} \prod_{j \in \mathcal{I}} z_j \), which is bilinear in continuous variables and multilinear in binary variables, we now characterize the convex hull of \( \varphi(x, z) = x_{1,2} \prod_{j \in \mathcal{I}} z_j \), in the extended space of McCormick-based constraints. The formulation is obtained as a disjunctive union of the sets \( Z^0 \) and \( Z^1 \), given by:

\[
Z^0 = \left\{ (x, \tilde{\varphi}, \tilde{x}_z, z, \tilde{z}) \in \mathbb{R}^3 \times [0, 1]^{\mathcal{J}+1} : \begin{array}{c}
\tilde{\varphi} = 0, \quad \tilde{x}_z = 0, \\
1^T \tilde{z} \leq |\mathcal{J}| - 1, \\
\tilde{z} = 0
\end{array} \right\}
\]

\[
Z^1 = \left\{ (x, \tilde{\varphi}, \tilde{x}_z, z, \tilde{z}) \in (x, \tilde{\varphi})^{MC} \times \mathbb{R}^2 \times [0, 1]^{\mathcal{J}+1} : \begin{array}{c}
z = 1, \\
\tilde{z} = 1, \\
\tilde{x}_z = x
\end{array} \right\}
\]

We now define the set \( Z \) as follows:

\[
Z = \left\{ (x, \tilde{\varphi}, \tilde{x}_z, z, \tilde{z}) \in [\ell, u] \times \mathbb{R}^3 \times [0, 1]^{\mathcal{J}+1} : \begin{array}{c}
z \leq 1, \\
\tilde{z} \leq 1, \\
\tilde{z} \leq \tilde{x}_z, \\
\tilde{z} \leq \ell \cdot \tilde{\varphi} + u \cdot \tilde{z} - u \cdot \tilde{x}_z - u \cdot \tilde{z} - u \cdot \ell \cdot \tilde{z}, \\
\tilde{z} \cdot \ell \leq \tilde{x}_z \leq \ell \cdot z - u - (1 - \tilde{z}) \cdot \ell
\end{array} \right\}
\]

**Theorem 0.2.** \( \text{conv}(Z^0 \cup Z^1) = \overline{Z} \).

**Proof.** The proof of this theorem is very similar to that of Theorem 0.1. \( \square \)

A special case of this function, i.e., \( \varphi = x_{1,2}z \), has been dealt with in [2], where the authors derive a convex hull formulation in the space of original variables only when the variables \( (x_1, x_2) \) are forced to zero values when the binary variable \( z \) is assigned a zero value.

**Initial Results and Conclusions**

All formulations were solved on a laptop with an Intel(R) i7, 2.60GHz processor and 16GB of memory using Gurobi 7.5.2 with default options. As shown in (16), we consider an MINLP with a sum of 2k-linear MIMFs such that the feasible set is non-empty and admits non-trivial solutions.

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} (c_i x_i + d_i z_i) \\
\text{subject to} & \quad \sum_{i=1}^{n} \left| \prod_{j=i}^{i+k-1} x_{i,j} \right| \geq D, \\
& \quad x \in \{\ell, u\}, \\
& \quad z \in [0, 1]^n
\end{align*}
\]

In (16), \( c_i, d_i \) and \( \ell \) are independently assigned pseudorandom values on an open interval between 0 and 1, and \( u = 10 \ell \). For example, at \( k = 4 \) and \( n = 5 \), the constraint in (16) will be \( x_1 x_2 x_3 x_4 z_1 z_2 z_3 z_4 \geq D \). Applying \( \tilde{\varphi}^4 \) on (16) implies that every MIMF is replaced by a lifted variable.
say $\tilde{\varphi}_i$, such that $\sum_i \tilde{\varphi}_i \geq D$ and $\tilde{\varphi}$ admits the constraints from $\tilde{\mathcal{A}}^4$ in (7), thus creating a lower-bounding MILP for (16). For this MILP, we define

$$\text{LP gap} = \frac{\text{OPT} - \text{LB}}{\text{OPT}} \times 100,$$

where, $\text{OPT}$ and $\text{LB}$ correspond to MILP’s optimal and continuous relaxation objective values.

**TABLE 1.** $\tilde{\mathcal{A}}^4$ and $\tilde{\mathcal{A}}^{rmc}$ applied on (16) for $k = 4$ and $D = 0.7n$. Bold font represents best run times.

Table 1 shows the performance comparisons of formulations, $\tilde{\mathcal{A}}^4$ and $\tilde{\mathcal{A}}^{rmc}$ on double-quadrilinear functions. Clearly, $\tilde{\mathcal{A}}^4$ overall performs the best in terms of runtimes, both for MILPs and their LP relaxations. Though $\tilde{\mathcal{A}}^4$ does not necessarily capture the convex hull of an arbitrary sum of MIMFs, the LP gaps are very tight and indeed produce close-to integral solutions (gaps < 0.001%) on large instances, thus speeding up the convergence of MILPs. Another interesting observation is that $\tilde{\mathcal{A}}^{rmc}$, with recursive McCormick relaxations clearly loses on capturing the convex hull of individual MIMFs, thus producing weaker lower bounds to the original MINLP in (16). However, for $k = 2$ (double-bilinear) in (16), we observed that both $\tilde{\mathcal{A}}^4$ and $\tilde{\mathcal{A}}^{rmc}$ produced identical lower bounds, validating the bilinear convex hull result in (15). Further, for $k = 4$, though the number of extreme points grow up to “16” per MIMF, the numerical performance of $\tilde{\mathcal{A}}^4$ is still superior to $\tilde{\mathcal{A}}^{rmc}$, which closely represents state-of-the-art relaxation approaches applied in the literature.

**Summary** In this paper, we considered MIMFs and developed new convex relaxations based on the convex hull of the disjunctive union of these two sets of variables in an extended space. While this paper has made strides in tightening relaxations of MIMFs, there remain a number of important future directions including the characterization of the convex hull of an MIMF in the space of its original variables.

**Acknowledgements** The work was funded by the Center for Nonlinear Studies (CNLS) at LANL and the LANL’s directed research and development project “POD: A Polyhedral Outer-approximation, Dynamic-discretization optimization solver”. It was carried out under the auspices of the NNSA of the U.S. DOE at LANL under Contract No. DE-AC52-06NA25396.
