Abstract

We consider leptogenesis in a minimal $S_3$ extension of the standard model with an additional $Z_2$ symmetry in the leptonic sector. It is found that the CP phase appearing in the neutrino mixing is the same as that for the CP asymmetries responsible for leptogenesis. Because of the discrete $S_3 \times Z_2$ flavor symmetries, the CP asymmetries are strongly suppressed. We therefore assume that the resonant enhancement of the CP asymmetries takes place to obtain a realistic size of baryon number asymmetry in the universe. Three degenerate right-handed neutrino masses of $O(10)$ TeV are theoretically expected in this model.

I. INTRODUCTION

The baryon asymmetry in the universe brings cosmology and particle physics together [1]. A theoretically attractive idea [2] to produce baryon asymmetry is to apply a nonperturbative conversion mechanism of lepton asymmetry to baryon asymmetry, which exists as the sphaleron process in the standard model (SM) [3, 4]. For this idea to work, a sufficient amount of $B - L$ has to be generated [5] at temperatures $T$ between 100 and $10^{12}$ GeV [6, 7]. With the experimental fact that the neutrinos are massive [8, 9, 10, 11], it is plausible to believe that they are Majorana particles and hence the lepton number conservation is violated. This situation is nicely realized in the see-saw mechanism [12], which, after spontaneous symmetry breaking of $SU(2)_L \times U(1)_Y$, generates the Majorana masses of the left-handed neutrinos in the presence of heavy right-handed neutrinos.

With the see-saw mechanism at hand, it becomes indeed possible to explain the observed ratio of baryons to photons $\eta_B = (6.2 - 6.9) \times 10^{-10}$ [13] by leptogenesis [14]-[55]. However, the introduction of the right-handed neutrinos into the SM introduces additional ambiguities in the Yukawa sector. Because of these ambiguities, the theoretical value of $\eta_B$ depends on many independent parameters, so that it would be very difficult to make quantitative tests of the different mechanisms involved to produce baryon asymmetry. The origin of these ambiguities in the Yukawa sector in the SM is the missing of a more strict theoretical guide to construct the Yukawa sector.

A natural guidance to constrain the Yukawa sector is a flavor symmetry. Although there are attractive continues symmetries, we would like to consider discrete symmetries, especially nonabelian discrete symmetries $^1$. However, experimental data require that within the framework of the SM any nonabelian flavor symmetry has to be hardly broken at low energy. If the Higgs sector of the SM is so extended that a certain set of Higgs fields belong to a nontrivial representation of a nonabelian flavor group, phenomenologically viable possibilities may arise $^2$. The smallest nonabelian discrete group is $S_3$. In this paper, we would like to consider a minimal $S_3$ invariant extension of the SM [66, 67], in which $S_3$ is not

1 Earlier papers on permutation symmetries are [56, 57, 58, 59, 60, 61, 62, 63] for instance. See [64] for a review.
2 Recent, phenomenologically viable models based on nonabelian discrete flavor symmetries $S_3, D_4, A_4, O_4,$ and $Q_6$ and also on a product of abelian discrete symmetries have been recently constructed in [65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78] and [79, 80, 81], respectively. See also [82]-[88].
hardly broken at low energy, and consequently, the Yukawa sector is much more constrained than in the SM. In Sect. II we define the model, while investigating the independent phases in the leptonic sector. We discuss neutrino mixing and CP phase in Sect. III, and express the average neutrino mass $<m_{ee}>$ appearing in neutrinoless double $\beta$ decay as a function of the independent phase $\phi_{\nu}$. Leptogenesis and baryon asymmetry are considered in Sect. IV, while Sect. V is devoted to summarizing our findings.

II. $S_3$ INVARIANT EXTENSION OF THE STANDARD MODEL

A. Leptonic sector

We assume that the three generations of quarks and leptons belong to the reducible representation of $S_3$ $3 = 1 + 2$. We also introduce an $S_3$ doublet Higgs fields, $H_i (i = 1, 2)$, as well as an $S_3$ singlet Higgs, $H_S$. The $S_3$ invariant Yukawa interactions in the leptonic sector is given by

\[
\mathcal{L}_Y = -y_1 \overline{L}_i H_S E_{iR} - y_3 \overline{L}_S H_S E_{SR} - y_2 f_{ijk} \overline{L}_i H_j E_{kR} - y_4 \overline{L}_S H_i E_{iR} - y_5 \overline{L}_i H_i E_{SR} - h_1 \overline{L}_i \epsilon H_S^* \nu_{iR} - h_3 \overline{L}_S \epsilon H_S^* \nu_{SR} - h_2 f_{ijk} \overline{L}_i \epsilon H_j^* \nu_{kR} - h_4 \overline{L}_S \epsilon H_i^* \nu_{SR} - h_5 \overline{L}_i \epsilon H_i^* \nu_{SR} - \frac{1}{2} M_1 \overline{\nu}_{iR} \nu_{iR} - \frac{1}{2} M_S \overline{\nu}_{SR} \nu_{SR} + h.c., \ i, j, k = 1, 2,
\]

where

\[
f_{121} = f_{211} = f_{112} = -f_{222} = 1, \ f_{111} = f_{221} = f_{122} = f_{212} = 0.
\]

Here $L, E_R, \nu_R$ and $H$ stand for left-handed charged lepton $SU(2)_L$ doublets, right-handed charged leptons, right-handed neutrinos and Higgs $SU(2)_L$ doublets, respectively. $\mathcal{L}_Y$ is the most general renormalizable form that is $S_3$ invariant. In an additional abelian discrete symmetry $Z_2$ has been introduced to achieve a further simplification of the leptonic sector. The $Z_2$ parity assignment is:

\[
+ \text{ for } H_i, L_S, L_i, E_{iR}, E_{SR}, \nu_{iR} \text{ and } - \text{ for } H_S, \nu_{SR}.
\]

\[^3\text{In }[66] \text{ it is incorrectly stated that there is no CP phase in the present model.}\]
This $Z_2$ forces the following Yukawa couplings to vanish\footnote{This symmetry is hardly broken in the quark sector. Therefore, there will be radiative corrections coming from that sector. However, they appear first at the two-loop level, and so, one may assume that they are small.}:

\[ y_1, y_3, h_1 \text{ and } h_5. \] \hfill (4)

Let us next figure out the structure of CP phases. To this end, we introduce phases explicitly as follows:

\[ y_a \rightarrow e^{i p_a} y_a \ (a = 2, 4, 5), \ h_a \rightarrow e^{i p_a} h_a \ (a = 2, 4, 3) \] \hfill (5)

for the Yukawa couplings, where $y$’s and $h$’s on the right-hand side are assumed to be real and $-\pi/2 \leq p \leq \pi/2$, and similarly for the fields

\[ L_i \rightarrow e^{i p_L} L_i, \ L_S \rightarrow e^{i p_L} L_S, \ E_{iR} \rightarrow e^{i p_E} E_{iR}, \ E_{SR} \rightarrow e^{i p_E} E_{SR}, \]

\[ \nu_{iR} \rightarrow e^{i p} \nu_{iR}, \ \nu_{SR} \rightarrow e^{i p} \nu_{SR}. \] \hfill (6)

The phases of the right-handed neutrinos are used to absorb the phase of their Majorana masses $M_1$ and $M_S$. The phases of $y_2, y_4$ and $y_5$ can be rotated away if

\[ p_L = p_{y_2} + p_E, \ p_{LS} = p_{y_4} + p_E, \ p_{ES} = -p_{y_5} + p_{y_2} + p_E \] \hfill (7)

are satisfied. So, only one free phase is left, which we assume to be $p_L$. Then we cancel the phase of $h_2$ by $p_L$, which implies

\[ p_L = p_{h_2}. \] \hfill (8)

No further phase rotation is possible, so that $h_3$ and $h_4$ can be complex in general. (Since for the mass matrices one can rotate the left-handed neutrinos and left-handed charged leptons separately, one can eliminate one more phase so that the neutrino mass matrix has only one independent phase.) However, as we will see in the following discussions that only the phase difference $p_{h_3} - p_{h_4}$ enters into the mass matrix of the left-handed neutrinos and into the CP asymmetries responsible for leptogenesis.
B. Higgs sector

Before we come to discuss the double beta decay of the present model, we would like to briefly summarize the feature of the Higgs sector. The present model contains five neutral physical Higgs fields; two scalars and three pseudo scalars. Their couplings to the fermions are basically fixed \[66\], but the Yukawa sector does not satisfy the general conditions \[89, 90\] to suppress the tree level FCNCs. The only way to suppress the tree level FCNCs in the model is to make the Higgs particles sufficiently heavy \(\sim 10 \text{ TeV}\), which mediate the tree level FCNCs. So, it is important to study the Higgs potential. The \(S_3\) invariant Higgs potential \(V_H\) has been studied in \[56, 91\]. It has turned out that all the Higgs masses obtained from \(V_H\) are proportional to VEVs, so that unless one discards the triviality constraint, they can be at most of the order of several hundreds GeV. These values are too small to suppress FCNCs \[56, 62\].

One of the ways out of the problem is to break the \(S_3\) symmetry softly; as soft as possible to preserve the prediction from \(S_3 \times Z_2\) in the Yukawa sector. It has been observed that if the Higgs potential \(V_H\) respects \(S_3\) as well as \(Z_2\) invariance (\(Z_2\) is defined in (3)), it has an additional abelian discrete symmetry \(S'_2\)

\[H_1 \leftrightarrow H_2,\]

which is not a subgroup of the original \(S_3\). Therefore, we assume that the soft breaking mass term \(\hat{V}_{SB}\) also respects this discrete symmetry \(S'_2\), while breaking \(S_3 \times Z_2\) softly. The most general form is

\[\hat{V}_{SB} = -\mu_{SB1}^2 (H_1^\dagger H_2 + h.c) - \mu_{SB2}^2 [H_S^\dagger (H_1 + H_2) + h.c].\]

(10)

It has been shown in \[91\] that for the \(S_3 \times Z_2 \times S'_2\) invariant Higgs potential with \(10\), only \(S'_2\) invariant VEVs (under the assumption that \(< H_S > \neq 0\) and \(\mu_{SB1,2}\) are real)

\[< H_S > \neq 0, \quad < H_1 > = < H_2 > \neq 0.\]

(11)

can satisfy the condition that all the physical Higgs bosons, except one neutral physical Higgs boson, can become heavy \(\sim 10 \text{ TeV}\) without having a problem with triviality. We would like to emphasize that the \(S'_2\) invariant VEVs \(11\) are the most economic VEVs in the sense that the freedom of VEVs can be completely absorbed into the Yukawa couplings.
so that we can derive the most general form for the fermion mass matrices

\[ M = \begin{pmatrix} m_1 + m_2 & m_2 & m_5 \\ m_2 & m_1 - m_2 & m_5 \\ m_4 & m_4 & m_3 \end{pmatrix} \]  

(12)

without referring to the details of the Higgs potential.

To diagonalize the Higgs fields, we redefine the Higgs fields as

\[ H_\pm = \frac{1}{\sqrt{2}} (H_1 \pm H_2), \]

\[ H_L = \cos \gamma H_S + \sin \gamma H_+ , \quad H_H = - \sin \gamma H_S + \cos \gamma H_+ \]  

(13)

and

\[ H_- = \left( \begin{array}{c} h_- \\ \frac{1}{\sqrt{2}} (h_0^L + i\chi_-) \end{array} \right), \quad H_L = \left( \begin{array}{c} h_L \\ \frac{1}{\sqrt{2}} (v + h_0^L + i\chi_L) \end{array} \right), \]

\[ H_H = \left( \begin{array}{c} h_H \\ \frac{1}{\sqrt{2}} (h_0^H + i\chi_H) \end{array} \right), \]  

(14)

(15)

where

\[ v_+ = < h_0^L > , \quad v_S = < h_0^S >, \quad v = (v_+^2 + v_S^2)^{1/2} = 246 \text{ GeV}, \]

\[ \sin \gamma = v_+ / v, \quad \cos \gamma = v_S / v. \]  

(16)

As we see from (14), only \( H_L \) has VEV, and therefore, one can identify \( H_L \) as the SM Higgs doublet. In fact, \( h_L \) and \( \chi_L \) are the would-be Goldstone bosons. However, the neutral Higgs \( h_L^0 \) is not a mass eigenstate; it mixes with \( h_H^0 \). The mixing is of \( O(v^2/\mu_{SB}^2) \) which is at most \( \sim 10^{-3} \). It is possible to kill this mixing by fine tuning of the couplings in the Higgs potential. In the following we assume this. Under this assumption, all the Higgs fields defined in (14) and (15) are mass eigenstates. In Table 1, their masses are given under the assumption that \( \mu_{SB1}^2, \mu_{SB2}^2 >> v^2 \).
Higgs & mass \\
\hline
h_- & m_{h_-}^2 \simeq 2\mu_{SB1}^2 + \sqrt{2}\mu_{SB2}^2 \cot \gamma \\
h_0 & m_{h_0}^2 \simeq m_{h_-}^2 \\
\chi_- & m_{\chi_-}^2 \simeq m_{h_-}^2 \\
h_L & \text{Would-be Goldstone} \\
h_0^L & m_{h_0^L} = O(v^2) \\
\chi_L & \text{Would-be Goldstone} \\
h_H & m_{h_H}^2 \simeq 2\sqrt{2}\mu_{SB2}^2 / \sin 2\gamma \\
h_0^H & m_{h_0^H} \simeq m_{h_H}^2 \\
\chi_H & m_{\chi_H} \simeq m_{h_H}^2 \\
\hline
\end{tabular}

**TABLE I:** Mass of the Higgs particles. $m_{h_{-,H}}$ should be larger than $\sim 10$ TeV to sufficiently suppress the tree level FCNCs.

### III. NEUTRINO MIXING AND NEUTRINOLESS DOUBLE $\beta$ DECAY

The fermion masses are generated from the $S'_2$ invariant VEVs [16]. Because of the $Z_2$ symmetry [3], the mass matrix for the charged leptons becomes

\[ M_e = \begin{pmatrix} m_2 & m_2 & m_5 \\ m_2 & -m_2 & m_5 \\ m_4 & m_4 & 0 \end{pmatrix}, \tag{17} \]

where

\[ m_2 = vy_2 \sin \gamma / \sqrt{2}, m_4 = vy_4 \sin \gamma / \sqrt{2}, m_5 = vy_5 \sin \gamma / \sqrt{2}. \tag{18} \]

As discussed previously, the phase of all the nonvanishing Yukawa couplings $y_2, y_4$ and $y_5$ can be rotated away. So, all the mass parameters appearing in (17) are real. Diagonalization of the mass matrices is straightforward. The mass eigen values are approximately given by

\[ m_e^2 = \frac{(m_4m_5)^2}{(m_2)^2 + (m_5)^2} + O((m_4)^4), \tag{19} \]

\[ m_\mu^2 = 2(m_2)^2 + (m_4)^2 + O((m_4)^4), \tag{20} \]

\[ m_\tau^2 = 2[ (m_2)^2 + (m_5)^2 ] + \frac{(m_4m_2)^2}{(m_2)^2 + (m_5)^2} + O((m_4)^4). \tag{21} \]
Concrete values are given as $m_4/m_5 \simeq 0.00041$ and $m_2/m_5 \simeq 0.0596$ and $m_5 \simeq 1254$ MeV to obtain $m_e = 0.51$ MeV, $m_\mu = 105.7$ MeV and $m_\tau = 1777$ MeV. The diagonalizing unitary matrices (i.e., $U^T_{eL}M_eU_{eR}$) assume a simple form in the $m_e \to 0$ limit, which is equivalent to the $m_4 \to 0$ limit. $U_{eL}$ in this limit is

$$U^0_{eL} = \begin{pmatrix} 0 & -1/\sqrt{2} & 1/\sqrt{2} \\ 0 & 1/\sqrt{2} & 1/\sqrt{2} \\ 1 & 0 & 0 \end{pmatrix}. \tag{22}$$

We shall consider this limit later on.

Similarly, the Dirac neutrino mass matrix is given by

$$M_D = \begin{pmatrix} m_{D2} & m_{D2} & 0 \\ m_{D2} & -m_{D2} & 0 \\ m_{D4} & m_{D4} & m_{D3} \end{pmatrix}. \tag{23}$$

where

$$m_{D2} = v h_2 \sin \gamma / \sqrt{2}, m_{D4} = v h_4 e^{i p_{h4}} \sin \gamma / \sqrt{2},$$

$$m_{D3} = v \cos \gamma h_3 e^{i p_{h3}}. \tag{24}$$

For the mass matrices one can rotate the left-handed charged leptons and the left-handed neutrinos separately. So, we rotate $\nu_{SL}$ to absorb the phase of $m_{D4}$, and we rewrite $M_D$ as

$$M_D = \begin{pmatrix} m_{D2} & m_{D2} & 0 \\ m_{D2} & -m_{D2} & 0 \\ m_{D4} & m_{D4} & m_{D3} \exp i \varphi_3 \end{pmatrix}, \tag{25}$$

where

$$\varphi_3 = p_{h4} - p_{h3} \left(-\pi/2 \leq \varphi_3 \leq \pi/2\right), \tag{26}$$

and the Dirac mass parameters $m_D$’s in (25) are all real numbers.

The Majorana masses for $\nu_L$ can be obtained from the see-saw mechanism, and the corresponding mass matrix is given by $M_\nu = M_D \tilde{M}^{-1} (M_D)^T$, where $\tilde{M} = \text{diag}(M_1, M_1, M_S)$. We have assumed that the phases of the right-handed neutrinos are used to rotate away the phase of $M_1$ and $M_S$. So, we may assume that they are real positive numbers. To express
in a simple form we rescale the Dirac neutrino masses according to

\[ m_{D2} \rightarrow \rho_2 = m_{D2}/\sqrt{M_1}, \quad m_{D4} \rightarrow \rho_4 = m_{D4}/\sqrt{M_1}, \]

\[ m_{D3} \rightarrow \rho_3 = m_{D3}/\sqrt{M_S}. \]  

(27)

Thanks to the \( Z_2 \) symmetry (3), the mass matrix \( M_\nu \) takes a simple form

\[
M_\nu = M_D \bar{M}^{-1} (M_D)^T
\]

\[
= \begin{pmatrix}
2(\rho_2)^2 & 2\rho_2\rho_4 & 0 \\
0 & 2(\rho_2)^2 & 0 \\
2\rho_2\rho_4 & 0 & 2(\rho_4)^2 + (\rho_3)^2 \exp i2\varphi_3
\end{pmatrix}.
\]  

(28)

The \( \rho \)'s in (28) are real numbers. One can convince oneself that \( M_\nu \) can be diagonalized as

\[
U_\nu^T M_\nu U_\nu = \begin{pmatrix}
m_{\nu_1}e^{i\phi_1 - i\phi_\nu} & 0 & 0 \\
0 & m_{\nu_2}e^{i\phi_2 + i\phi_\nu} & 0 \\
0 & 0 & m_{\nu_3}
\end{pmatrix},
\]  

(29)

where

\[
U_\nu = \begin{pmatrix}
-s_{12} & c_{12}e^{i\phi_\nu} & 0 \\
0 & 0 & 1 \\
c_{12}e^{-i\phi_\nu} & s_{12} & 0
\end{pmatrix},
\]  

(30)

\[ m_{\nu_3} \sin \phi_\nu = m_{\nu_2} \sin \phi_2 = m_{\nu_1} \sin \phi_1, \quad 2\varphi_3 = \phi_1 + \phi_2 \]  

(31)

\[ m_{\nu_3} = 2\rho_2, \quad \frac{m_{\nu_1}m_{\nu_2}}{m_{\nu_3}} = \rho_3^2, \]  

(32)

\[ \tan \phi_\nu = \frac{\rho_3^2 \sin 2\varphi_3}{2(\rho_2^2 + \rho_4^2) + \rho_3^2 \cos 2\varphi_3}, \]  

(33)

and \( c_{12} = \cos \theta_{12} \) and \( s_{12} = \sin \theta_{12} \). We also find that

\[ \tan^2 \theta_{12} = \frac{(m_{\nu_2}^2 - m_{\nu_3}^2 \sin^2 \phi_\nu)^{1/2} - m_{\nu_3} \cos \phi_\nu}{(m_{\nu_3}^2 - m_{\nu_2}^2 \sin^2 \phi_\nu)^{1/2} + m_{\nu_3} \cos \phi_\nu}, \]  

(34)

from which we find

\[ \frac{m_{\nu_2}^2}{\Delta m_{23}^2} = \frac{(1 + 2t_{12}^2 + t_{12}^4 - rt_{12}^4)^2}{4t_{12}(1 + t_{12}^2)(1 + t_{12}^2 - rt_{12}^4) \cos^2 \phi_\nu} - \tan^2 \phi_\nu \]  

(35)

\[ \simeq \frac{1}{\sin^2 2\theta_{12} \cos^2 \phi_\nu} - \tan^2 \phi_\nu \text{ for } |r| < < 1, \]  

(36)
where \( t_{12} = \tan \theta_{12}, r = \Delta m^2_{21}/\Delta m^2_{23} \). It can also be shown that only an inverted mass spectrum

\[
m_{\nu_3} < m_{\nu_1}, m_{\nu_2}
\]

(37)
is consistent with the experimental constraint \( |\Delta m^2_{21}| < |\Delta m^2_{23}| \) in the present model. Note that Eq. (32) is satisfied for

\[
2\varphi_3 = \phi_1 + \phi_2 \sim \pm \pi
\]

(38)
and NOT for \( \phi_1 \sim \phi_2 \). That is, if \( 2\varphi_3 \sim (+)\pi \), then \( \cos \phi_1 < (>)0 \) and \( \cos \phi_2 > (>)0 \). Now the product \( U^\dagger_{eL} P U_{\nu} \) defines a neutrino mixing matrix \( V_{\text{MNS}} \), where

\[
P = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & e^{i\phi_4}
\end{pmatrix}.
\]

For our purpose it is sufficient to use the approximate unitary matrix \( U^0_{eL} \) given in (22) which is obtained in the limit that the electron mass is zero. We denote the approximate neutrino mixing matrix by \( V^0_{\text{MNS}} \) obtained from \( U^0_{eL} \) and \( U_{\nu} \). The product \( U^0_{eL} P U_{\nu} \) can be brought by an appropriate phase transformation to a popular form

\[
V_{\text{MNS}} \simeq V^0_{\text{MNS}} = \begin{pmatrix}
c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\
-s_{12}c_{23} - c_{12}s_{23}s_{13} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & c_{23}c_{13} \\
s_{12}s_{23} - c_{12}c_{23}s_{13} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}s_{13}
\end{pmatrix}
\]

\[
\times \begin{pmatrix}
1 & 0 & 0 \\
0 & e^{i\alpha} & 0 \\
0 & 0 & e^{i\beta}
\end{pmatrix},
\]

(39)
with

\[
s_{13} = 0, \quad t_{23} = \frac{s_{23}}{c_{23}} = 1,
\]

\[
sin 2\alpha = \sin(\phi_1 - \phi_2)
\]

\[
= \pm \frac{m_{\nu_3}}{m_{\nu_1}m_{\nu_2}} \left( \sqrt{m_{\nu_2}^2 - m_{\nu_3}^2 \sin^2 \phi_\nu} + \sqrt{m_{\nu_1}^2 - m_{\nu_3}^2 \sin^2 \phi_\nu} \right)
\]

\( \simeq \pm 2 \sin \phi_\nu (m_{\nu_1}/m_{\nu_2}) \sqrt{1 - (m_{\nu_3}/m_{\nu_2})^2 \sin^2 \phi_\nu}, \)

\[
sin 2\beta = \sin(\phi_1 - \phi_\nu)
\]

\[
= \pm \frac{\sin \phi_\nu}{m_{\nu_1}} \left( m_{\nu_3} \sqrt{1 - \sin^2 \phi_\nu} + \sqrt{m_{\nu_1}^2 - m_{\nu_3}^2 \sin^2 \phi_\nu} \right)
\]

(42)
for $2\varphi_2 \sim \pm \pi$, where $\phi_1, \phi_2$ and $\phi_\nu$ are defined in (32)\footnote{5}.

The effective Majorana mass $\langle m_{ee} \rangle$ in neutrinoless double $\beta$ decay is given by

$$\langle m_{ee} \rangle = |\sum_{i=1}^{3} m_{\nu_i} V_{ei}^2| \simeq |m_{\nu_1} c_{12}^2 + m_{\nu_2} s_{12}^2 \exp 2i\alpha|,\tag{43}$$

where $\phi_\nu$ and $\alpha$ are given in (32) and (41), respectively. In Fig. 1 we plot $\langle m_{ee} \rangle$ as a function of $\sin \phi_\nu$ for $\sin^2 \theta_{12} = 0.3, \Delta m_{21}^2 = 6.9 \times 10^{-5}$ eV$^2$ and $\Delta m_{23}^2 = 1.4, 2.3, 3.0 \times 10^{-3}$ eV$^2$\footnote{6}. As we can see from Fig. 1, the effective Majorana mass stays at about its minimal value $\langle m_{ee} \rangle_{\text{min}}$ for a wide range of $\sin \phi_\nu$. Since $\langle m_{ee} \rangle_{\text{min}}$ is approximately equal to $\sqrt{\Delta m_{23}^2 / \sin 2\theta_{12}} = (0.034 - 0.069)$ eV, it is consistent with recent experiments\footnote{13, 94} and is within an accessible range of future experiments\footnote{95}.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig1.png}
\caption{The effective Majorana mass $\langle m_{ee} \rangle$ as a function of $\sin \phi_\nu$ with $\sin^2 \theta_{12} = 0.3$ and $\Delta m_{21}^2 = 6.9 \times 10^{-5}$ eV$^2$. The dashed, solid and dot-dashed lines stand for $\Delta m_{23}^2 = 1.4, 2.3$ and $3.0 \times 10^{-3}$ eV$^2$, respectively. The $\Delta m_{21}^2$ dependence is very small.}
\end{figure}

\footnote{5}{For a nonvanishing electron mass, we have $s_{13} \simeq m_e / \sqrt{2} m_\mu \simeq 0.0034$ and $\delta = p_{h_4} - \phi_\nu$. Unfortunately, this value of $s_{13}$ is too small to be measured\footnote{92}.}
Noticing that (32), (38) and (41), one obtains 6 (for $2\varphi_3 \sim -\pi$)

$$\sin 2\varphi_3 = -\frac{m_{\nu_3}}{m_{\nu_1}} \sin \phi_\nu \left[ 1 - \left( \frac{m_{\nu_3}}{m_{\nu_2}} \sin \phi_\nu \right)^2 \right]^{1/2} + \frac{m_{\nu_2}}{m_{\nu_1}} \sin \phi_\nu \left[ 1 - \left( \frac{m_{\nu_3}}{m_{\nu_1}} \sin \phi_\nu \right)^2 \right]^{1/2}$$

$$\simeq -\frac{m_{\nu_3}}{2m_{\nu_2}} \frac{\Delta m_{21}^2 \sin \phi_\nu}{1 - \left( m_{\nu_3}/m_{\nu_2} \right)^2 \sin^2 \phi_\nu}^{1/2},$$

(44)

where $\Delta m_{21}^2/m_{\nu_2}^2 << 1$ is assumed. As one sees from (35), (37), (38), (41) and (42) that once $\theta_{12}, \Delta m_{21}^2$ and $\Delta m_{23}^2$ are given, the only free parameter is $\phi_\nu$. Numerically one finds

$$\sin 2\varphi_3 \simeq -(0.0034 - 0.013) \sin \phi_\nu,$$

(45)

where we have used: $\sin^2 \theta_{12} = 0.3, 1.4$ eV$^2 \lesssim \Delta m_{21}^2 \times 10^5 \lesssim 3.0$ eV$^2$ and $6.1$ eV$^2 \lesssim \Delta m_{23}^2 \times 10^3 \lesssim 8.4$ eV$^2$. Therefore, CP asymmetry being proportional to $\sin 2\varphi_3$ is very small in the present model, even if the CP phase appearing in neutrinoless double $\beta$ decays is large 7.

FIG. 2: $\sin 2\varphi_3$ versus $\sin \phi_\nu$ with $\sin^2 \theta_{12} = 0.3$ in the case of $2\varphi_3 \sim +\pi$. The case of $2\varphi_3 \sim -\pi$ is the same except for the sign of $\sin 2\varphi_3$. The dot-dashed, solid and dashed lines stand for $(\Delta m_{23}^2 \times 10^3, \Delta m_{21}^2 \times 10^5) = (3.0, 6.1), (2.3, 6.9)$ and $(1.4, 8.4)$ eV$^2$, respectively.

6 As we will see in the next section, the ratio of baryons to photons $\eta_B$ is proportional to $-\sin 2\varphi_3$.

7 Models in which the CP phases in the neutrino mixing matrix are closely related to those for leptogenesis have been considered, for instance, in [42]-[45].
IV. LEPTOGENESIS

A. CP phase

Before we start to compute CP asymmetries, we first would like to consider the mixing of the charged leptons in the limit that the mass of the electron vanishes. That is, we approximate the unitary matrix which defines the mass eigenstates of the charged leptons by $U^0_{eL}$ (22). We next rewrite the Yukawa interactions (1) in terms of the mass eigenstates for the Higgses (14)-(15) and the charged leptons. The relevant part for leptogenesis becomes

$$L_h = -h_{iJ}^* \overline{L}_I e^* \nu_{JR} - h_{iJ}^H \overline{L}_I \epsilon H^*_{iJ} \nu_{JR} - h_{iJ}^L \overline{L}_I \epsilon H^*_{L} \nu_{JR}$$

with

$$\hat{L} = U^0_{eL} L = \left( \begin{array}{c} \nu_{eL} \\ \nu_{\mu L} \\ \nu_{\tau L} \end{array} \right),$$

where

$$h_{iJ}^H = \left( \begin{array}{ccc} \cos \gamma h_{4} e^{ip_{h_{4}}} / \sqrt{2} & \cos \gamma h_{4} e^{ip_{h_{4}}} / \sqrt{2} & -\sin \gamma h_{3} e^{ip_{h_{3}}} \\ 0 & -\cos \gamma h_{2} & 0 \\ \cos \gamma h_{2} & 0 & 0 \end{array} \right),$$

$$h_{iJ}^L = \left( \begin{array}{ccc} \sin \gamma h_{4} e^{ip_{h_{4}}} / \sqrt{2} & \sin \gamma h_{4} e^{ip_{h_{4}}} / \sqrt{2} & \cos \gamma h_{3} e^{ip_{h_{3}}} \\ 0 & -\sin \gamma h_{2} & 0 \\ \sin \gamma h_{2} & 0 & 0 \end{array} \right),$$

$$h_{iJ}^- = \left( \begin{array}{ccc} h_{4} e^{ip_{h_{4}}} / \sqrt{2} & -h_{4} e^{ip_{h_{4}}} / \sqrt{2} & 0 \\ h_{2} & 0 & 0 \\ 0 & h_{2} & 0 \end{array} \right),$$

where $\gamma$ is defined in (16).

There are two types of diagrams that contribute to CP asymmetries, vertex diagrams and self-energy diagrams. Nonvanishing CP asymmetries are proportional to the imaginary part of $(h_{KJ}^* h_{KJ}^*)^2$. In the present case, there are three Higgs fields, and one finds that if one neglects the mass difference of the Higgs bosons, the vertex correction is proportional to the imaginary part of

$$\sum_{J,K,M} \sum_{A,B=H,L} (h_{JH}^A h_{JK}^B) (h_{MI}^A h_{MK}^B).$$
while the self-energy correction is proportional to the imaginary part of

$$
\sum_{J,K,M} \sum_{A,B=H,L} (h_{JK}^A h_{JK}^{A*})(h_{MI}^B h_{MK}^{B*}).
$$

(52)

Since \( h_{11} \) and \( h_{12} \) have the same phase, only the case \( I = 1, 2, K = 3 \) or \( I = 3, K = 1, 2 \) yields nonvanishing CP asymmetries. Therefore, the matrix \( h_{IJ}^\dagger \) cannot contribute to CP asymmetries. Moreover, since \( h_{i3}^{H,L} = 0 \) (\( i = 2, 3 \)), both the vertex and self-energy contributions become proportional to the imaginary part of

$$
\sum_{A,B=H,L} (h_{1i}^A h_{13}^{A*})(h_{1i}^B h_{13}^{B*}), i = 1, 2.
$$

(53)

However, from (48) and (49) we obtain

$$
h_{1i}^H h_{13}^{H*} + h_{1i}^L h_{13}^{L*} = 0,
$$

(54)

implying that CP asymmetries vanish, if the mass differences of the Higgs bosons are neglected. That is, CP asymmetries, generated in one-loop with \( H_L \) and \( H_H \) exchanges, cancel with each other. In the presence of the soft \( S_3 \times Z_2 \) breaking mass terms (10), the mass of \( H_H \) can be considerably different from that of \( H_L \), as we can see from Table 1. Consequently, there will be nonvanishing CP asymmetries in a realistic case, in which \( H_+ \) and \( H_H \) are made heavy by the soft \( S_3 \times Z_2 \) breaking terms to suppress the tree level FCNCs.

After so many discussions about the \( S_3 \) limit, we find that

$$
\text{Im} \left[ h_{1i}^{H,L} h_{1J}^{H,L*} \right] \sim (h_3 h_4)^2 \sin 2(p_{h_3} - p_{h_4})(h_3 h_4)^2 = - (h_3 h_4)^2 \sin 2\varphi_3
$$

(55)

with \( I = 1, 2, J = 3 \) or \( I = 3, J = 1, 2 \),

where \( \varphi_3 \) is given in (26), which is the only phase left over in the neutrino mass matrix. Therefore, the CP phase appearing in the neutrino mixing is the same as that for CP asymmetries.

**B. CP asymmetries and Baryon number asymmetry**

We first calculate the total decay width of the right-handed neutrinos. The relevant parts of the Yukawa interactions for this purpose are given in (46)-(50). For the \( S_3 \) singlet
right-handed neutrino $\nu_{SR}$ one finds

$$
\Gamma_{ST} = \Gamma_S[l + H_L] + \Gamma_S[l + H_H] + \Gamma_S[l^c + H_H] + \Gamma_S[l^c + H_H^*] \\
= \frac{1}{8\pi} h_3^2 M_S \left[ \cos^2 \gamma + \sin^2 \gamma \left[ (1 - \frac{m_{h_H}^2}{M_S^2})^2 \theta(M_S - m_{h_H}) \right] \right] \tag{56}
$$

$$
\rightarrow \frac{1}{8\pi} h_3^2 M_S \quad \text{as} \quad m_{h_H}/M_S \rightarrow 0,
$$

$$
\rightarrow \frac{1}{8\pi} h_3^2 M_S \cos^2 \gamma = \frac{1}{8\pi} \left( \frac{m_{\nu_1} m_{\nu_2}}{m_{\nu_3}} \right) \left( \frac{M_S}{v^2} \right)^2 \quad \text{as} \quad m_{h_H}/M_S \rightarrow 1,
$$

where the first term result from the decay into the SM Higgs $H_L$, and the second term comes from the decay into $H_H$ with mass $m_{h_H}$. The last equality follows from (24), (25), (27) and (32). Similarly, one finds the total decay width of $\nu_{1R}$ and $\nu_{2R}$

$$
\Gamma_{1T} = \Gamma_{2T} \\
= \frac{1}{8\pi} \left( \frac{1}{2} h_4^2 + h_2^2 \right) M_1 \left[ \sin^2 \gamma + \cos^2 \gamma \left[ (1 - \frac{m_{h_H}^2}{M_1^2})^2 \theta(M_1 - m_{h_H}) \right] \right] \\
+ \left[ (1 - \frac{m_{h_H}^2}{M_1^2})^2 \theta(M_1 - m_{h_H}) \right] \tag{57}
$$

$$
\rightarrow \frac{1}{4\pi} \left( \frac{1}{2} h_4^2 + h_2^2 \right) M_1 \quad \text{as} \quad m_{h_H}/M_1, m_{h_-}/M_1 \rightarrow 0,
$$

$$
\rightarrow \frac{1}{8\pi} \left( \frac{1}{2} h_4^2 + h_2^2 \right) M_1 \sin^2 \gamma = \frac{1}{8\pi} (m_{\nu_3} + \rho_4^2) \left( \frac{M_1}{v} \right)^2 \quad \text{as} \quad m_{h_H}/M_1, m_{h_-}/M_1 \rightarrow 1,
$$

where $M_1 = M_2$ is assumed.

Because of (145), i.e. $|\sin \varphi_3| \lesssim 0.013$, one needs an enhancement to obtain a realistic value of baryon asymmetry. A nice way is the resonant enhancement [17, 18, 22], which we consider below 8. Since in this case the self-energy contributions to CP asymmetries dominate, we consider only them and neglect the contributions coming from the vertex diagrams. In the $S_3$ symmetric limit, $M_1$ is equal to $M_2$. This relation is modified to $M_1 = M_2 + O(m_{\nu})$ because of spontaneous symmetry breaking of $S_3$. So, there is a natural degeneracy of $\nu_{1R}$ and $\nu_{2R}$. However, there is no resonant enhancement between $\nu_{1R}$ and $\nu_{2R}$, because $\text{Im} h_{41}^{H,L} (h_{12}^{H,L})^* = 0$ as we can see from (18) and (19). Therefore, we may neglect this small correction, and we have to assume that $M_1 = M_2 \simeq M_S$. Introducing the notation

$$
\Delta M^2/M_S^2 = 1 - \frac{M_1^2}{M_S^2} = 1 - x \sim 0, \tag{58}
$$

8 See, for instance, [46]-[54] for recent models with resonant enhancement of leptogenesis. See also [55].
we find that
\[
\Delta \Gamma_S = \Gamma_S[l + H_L] + \Gamma_S[l + H_H] - \Gamma_S[l^c + H_L^c] - \Gamma_S[l^c + H_H^c] \\
= \frac{1}{64\pi^2}(h_4h_3)^2(\sin^2 \gamma \cos^2 \gamma) \sin 2\varphi_3 [1 - (1 - y_H)^2 \theta (1 - y_H)]^2 M_1 \frac{1}{1 - x},
\]
and \(\Delta \Gamma_1 \simeq \Delta \Gamma_S / 2\) for \(M_S \simeq M_1\). We have assumed that
\[
\Gamma_{ST,1T}/M_S << |\Delta M^2/M_S^2|,
\]
to use the approximate formula (59). From these calculations we obtain the CP asymmetries
\[
\epsilon_S = \frac{\Delta \Gamma_S}{\Gamma_{ST}} = \frac{1}{8\pi} h_4^2 \sin 2\varphi_3 \frac{[1 - (1 - y_H)^2 \theta (1 - y_H)]^2}{\sin^2 \gamma + (1 - y_H)^2 \theta (1 - y_H)/\cos^2 \gamma} \frac{\sqrt{x}}{1 - x},
\]
\[
\epsilon_1 = \epsilon_2 \simeq \frac{1}{2} \frac{\Gamma_{ST}}{\Gamma_{1T}} \epsilon_S,
\]
where
\[
y_H = \frac{m_{h_H}^2}{M_S^2},
\]
From (61) various limits may be obtained:
\[
\epsilon_S \to 0 \text{ as } y_H \to 0
\]
\[
\to \frac{1}{8\pi} h_4^2 \sin 2\varphi_3 \sin^2 \gamma \frac{\sqrt{x}}{1 - x} = \frac{1}{4\pi} \left( \frac{\rho_3^2 M_S^2}{\rho^2} \right) \sin 2\varphi_3 \frac{\sqrt{x}}{1 - x} \text{ as } y_H \to 1,
\]
where we have used (24), (25) and (27).

To be definite we assume \(y_H, y_- = m_{h^2}/M_S^2 \sim 1\) in the following discussions. Then only
the SM Higgs \(H_L\) contributes to CP asymmetries, and the phase \(\phi_v\) (or \(\varphi_3\)), \(\sin^2 \gamma\) (defined in \(\phi_v\)) and the effective mass
\[
M_{\text{eff}} = \frac{M_1}{1 - x} = \frac{M_S^2 M_1}{M_S^2 - M_1^2} \simeq \frac{M_S^3}{M_S^2 - M_1^2}
\]
are the only independent parameters. The lepton and baryon asymmetries \(Y_L = n_L/s\) and
\(Y_B = n_B/s\) \((n_L, n_B\) are the lepton and baryon number density, and \(s\) is the entropy density) are given by
\[
Y_L \simeq \kappa_S \epsilon_S / g^* + 2\kappa_1 \epsilon_1 / g^* \text{ with } g^* \simeq 120,
\]
\[
Y_B = \frac{\omega}{\omega - 1} Y_L,
\]
\[
\omega = \frac{8N_F + 4N_H}{22N_F + 13N_H} \simeq 0.34 \text{ for } N_F = 3, N_H = 3,
\]
where $k_{S(1)}$ is the dilution factor for the CP asymmetry $\epsilon_{S(1)}$, and $g^*$ is the effective number of degrees of freedom at the temperature $T = M_S \simeq M_1 = M_2$. We have taken into account all the degrees of freedom in $g^*$ including three right-handed neutrinos and three Higgs doublets. The dilution factors can be approximately written as \[ \kappa_S \simeq \frac{0.3}{K_S \ln K_S^{3/5}}, \quad \kappa_1 \simeq \frac{0.3}{K_1 \ln K_1^{3/5}}, \] (70)

where

\[
K_S = \frac{\Gamma_{ST}/H_{ST}}{\frac{h_3^2}{16\pi} \frac{M_{PL}}{1.66\sqrt{g^*} M_S}} = \frac{\rho_3^2}{8\pi v^2} \frac{M_{PL}}{1.66\sqrt{g^*}} \simeq 4.4 \times 10^2 \frac{(m_{\nu_1}/1 \text{ eV})(m_{\nu_2}/1 \text{ eV})}{(m_{\nu_3}/1 \text{ eV})}, \quad (71)
\]

\[
K_1 = \frac{\rho_4^2 + m_{\nu_3}}{8\pi v^2} \frac{M_{PL}}{1.66\sqrt{g^*}} \simeq 4.4 \times 10^2 (\rho_4^2 + m_{\nu_3})/1 \text{ eV}, \quad (72)
\]

where $\rho$’s are given in \ref{27}, and \ref{32} is used. [The approximate formula \ref{70} is applicable for $10 \lesssim K_{S,1} \lesssim 10^6$.] Note that using \ref{32} and \ref{33}, we can express $\rho_4^2$ in terms of the neutrino masses, $\phi_\nu$ and $\varphi_3$, and we find that the $\sin \gamma$ dependence in $\kappa_S$ and $\kappa_1$ cancels so that the lepton asymmetry and hence the baryon asymmetry $Y_B$ does not depend on $\sin \gamma$.

FIG. 3: $\eta_B$ versus $\sin \phi_\nu$. The dot-dashed, solid and dotted lines correspond to $M_{\text{eff}} = M_1/(1-x) = 4.0, 1.0, 0.7 \times 10^{13}$ GeV. We have assumed that $m_{h_H}, m_{h_-} \simeq M_S$ and used $\sin^2 \theta_{12} = 0.3, \Delta m^2_{23} = 2.3 \times 10^{-3}$ eV$^2$, $\Delta m^2_{21} = 6.9 \times 10^{-5}$ eV$^2$. The experimental value of $\eta_B \times 10^{10}$ is about 6.5 \ref{13}.
Finally, the ratio of the baryon number density to the photon density $\eta_B$ is given by

$$\eta_B \simeq 7.04Y_B \simeq -3.0 \times 10^{-2}(\kappa_S \epsilon_S + 2\kappa_1 \epsilon_1).$$

(74)

In Fig. 3 $\eta_B$ as a function of $\sin \phi_\nu$ is plotted for three different values of $M_{\text{eff}} = M_1/(1-x) = 4.0, 1.0, 0.7 \times 10^{13}$ GeV. As we see from Fig. 3, $\eta_B$ becomes maximal about $\sin \phi_\nu \simeq 0.75$. To obtain a realistic value of $n_B(\simeq 6.5 \times 10^{-10})$, the effective mass $|M_{\text{eff}}| = M_1/(1-x)$ should be of $0(10^{13})$ GeV, which means that $|1-x|$ has to be very small if $M_1$ is much smaller than $10^{13}$ GeV. We have to fine tune $M_S$ so that $|1-x| = |1-M^2_1/M^2_S| \simeq 10^{-9}$ for $M_S = 10$ TeV, for instance.

Let us at last discuss how fine this fine tuning is. A fine tuning is unnatural, if radiative corrections are larger than the fine tuning. One-loop radiative correction to the the right-handed neutrino masses may be estimated to be $\delta M \sim M h^2/16\pi^2$, where $h$ stands for the generic Yukawa couplings in (1), and $M$ for $M_1$ and $M_S$. So, the fine tuning of $(1-x)$ will be natural if

$$|1-x| = |1-M^2_1/M^2_S| > \delta M/M \sim h^2/16\pi^2.$$  

(75)

This condition, however, is weaker than the condition, $|M^2_S - M^2_1| >> M_S \Gamma_{ST}$ and $M_1 \Gamma_{1T}$, for the approximate formula (61) for one-loop self-energy diagram to be applicable [22]. The later condition is equivalent to

$$|1-x| >> \frac{1}{8\pi}(h^2_2 \sin^2 \gamma, h^2_2 \sin^2 \gamma, h^2_3 \cos^2 \gamma),$$

(76)

as we can see from (56) and (57). Therefore, if this condition is satisfied, the naturalness condition is automatically satisfied. The value of $h$ can be estimated from (24), (25), (27) and (32):

$$\frac{1}{8\pi}h^2_2 \sin^2 \gamma = \frac{1}{8\pi} \left(\frac{m_{\nu_3}}{v}\right) \left(\frac{M_1}{v}\right) \lesssim 10^{-13} \frac{M_1}{v},$$

(77)

$$\frac{1}{8\pi}h^2_1 \sin^2 \gamma = \frac{1}{16\pi} \left(\frac{m_{\nu_1} m_{\nu_2}}{m_{\nu_3} v} \tan \phi_\nu + \frac{m_{\nu_1} m_{\nu_2}}{m_{\nu_3} v} \cos 2\varphi_3 - \frac{m_{\nu_3}}{v}\right) \left(\frac{M_1}{v}\right)$$

$$\lesssim 10^{-13} \frac{M_1}{v},$$

(78)

$$\frac{1}{8\pi}h^2_3 \cos^2 \gamma = \frac{1}{8\pi} \left(\frac{m_{\nu_1} m_{\nu_2}}{m_{\nu_3} v}\right) \left(\frac{M_S}{v}\right) \lesssim 10^{-13} \frac{M_S}{v}.$$

(79)

The last inequality is obtained as follows. First we use the fact that in the present model an inverted hierarchy is predicted, and the experimental bound [13] $m_\nu \lesssim 0.2$ eV. The ratio
$|\sin 2\varphi_3/\tan \phi_\nu|$ is less than 0.013 because of (45). Further from (36) we find

$$m_{\nu_2}^2 \lesssim \frac{\Delta m_{23}^2}{\sin^2 2\theta_{12}}, \quad (80)$$

which gives

$$\frac{m_{\nu_2}^2}{m_{\nu_4}^2} = \left(1 - \frac{\Delta m_{23}^2}{m_{\nu_2}^2}\right)^{-1} \lesssim (1 - \sin^2 2\theta_{12})^{-1} = \cos^{-2} 2\theta_{12} \lesssim (4.6)^2. \quad (81)$$

Therefore, the condition (76) becomes

$$|1 - x| >> 10^{-13} \frac{M_1}{v}. \quad (82)$$

In terms of the effective mass $M_{\text{eff}}$ one finally finds

$$|M_{\text{eff}}| = \frac{M_1}{|1 - x|} \ll 10^{13} v \simeq 10^{15} \text{ GeV}. \quad (83)$$

Therefore, the criterion on the validity of the approximate formula (61) does not depend on the mass of the right-handed neutrinos. We recall that if (83) is satisfied, the naturalness condition (75) is automatically satisfied. For $M_S = 10$ TeV, for instance, we obtain $|1 - x| >> 4 \times 10^{-13}$ which implies that the fine tuning of $|1 - x| \simeq 10^{-9}$ to obtain $M_{\text{eff}} \simeq 10^{13}$ GeV is not only unnatural, but also the use of the approximate formula (61) is justified. The main reason of the independence of the right-handed neutrinos masses, $M_1$ and $M_S$, is the see-saw mechanism; the smaller $M_1$ and $M_S$ are, the finer fine tuning of $(1 - x)$ is allowed because of (76).

As we can see from (64), the CP asymmetries in the present model vanish if the Higgs masses are much smaller than the right-handed neutrinos masses. On one hand, the heavier the Higgs masses are, the finer fine tuning is needed in the Higgs sector. The constraints coming from FCNCs, on the other hand, require them to be larger than $O(10)$ TeV [56, 62]. Therefore, if we would like to explain the observed baryon asymmetry from leptogenesis within the framework of the present model, it is theoretically desirable to have right-handed neutrinos masses less than, say, $O(100)$ TeV.

V. CONCLUSION

In this paper we considered a minimal $S_3$ extension of the SM and investigated the possibility to explain the observed baryon asymmetry in the universe through leptogenesis
2. Below we would like to summarize our findings.

1. As in \([66, 67]\), we assumed an additional discrete symmetry \(E_3\) to increase the predictive power in the leptonic sector. The leptonic sector of the Yukawa interactions contains two independent phases \(p_{h_4}\) and \(p_{h_3}\). We found that in the limit that the electron mass vanishes, only the combination \(2\phi_3 = 2(p_{h_3} - p_{h_4})\) enters into the neutrino mixing matrix \(V_{MNS}\) as well as into the CP asymmetries \(\epsilon\)'s responsible for leptogenesis. (In this limit, \(V_{e3}\) vanishes.) However, because of \(E_3\), we obtained \(\delta_{CP} = |\sin 2\phi_3| \lesssim 0.013\).

2. It turned out that in the \(S_3\) symmetric limit, the CP asymmetries vanish. Therefore, within the framework of the minimal extension, one has to break \(S_3\) explicitly. To keep the predictivity in the Yukawa sector, we broke it softly. We note that the same soft masses were introduced in \([91]\) to make the heavy Higgses heavy \(\gtrsim O(10)\) TeV in order to suppress sufficiently the tree level FCNCs.

3. Because of \(|\sin 2\phi_3| \lesssim 0.013\), an enhancement is needed. A nice way is the resonant enhancement \([17, 18, 22]\), which requires all the right-handed neutrino masses are degenerate. \([M_1 = M_2, \text{up to very small corrections, is ensured by } S_3\text{ symmetry even if it is softly broken}]\)

4. We also found that the CP asymmetries vanish if the right-handed neutrino masses are much larger than the heavy Higgs masses. Therefore, to obtain a realistic size for baryon asymmetry, we have to assume that the right-handed neutrino masses are bounded from above. The heavy Higgs masses dictate the upper bound.

5. At last, we investigated the question of how fine the fine tuning needed for the degeneracy of the neutrino masses is. We found that if the criterion \(83\) on the validity of the approximate formula \(61\) is satisfied, the naturalness condition \(75\) is automatically satisfied. It turned out that the criterion \(83\) does not depend on the mass of the right-handed neutrinos.

As Fig. 3 presents, it is possible in the present model to explain the observed baryon asymmetry in the universe by leptogenesis. The basic parameters are: the right-handed neutrino masses, the heavy Higgs masses and the CP phase. Since the resonant enhancement
of CP asymmetries is assumed, and consequently, the degeneracy among the right-handed neutrino masses has to be very precise, it will be very difficult to experimentally determine the right-handed neutrino masses from a precise measurement of baryon asymmetry alone, even if the CP phase is precisely known. Experimentally, this is not a nice feature, but the model predicts (if the observed baryon asymmetry should be explained by leptogenesis) that there will be three extremely degenerate right-handed neutrinos whose masses are comparable with or less than the heavy Higgs masses. On one hand, the smaller the heavy Higgs masses are, the more natural is the fine tuning in the Higgs sector. The masses of the heavy Higgses, on the other hand, are $\gtrsim O(10)$ TeV to sufficiently suppress the tree level FCNCs. Therefore, we may theoretically expect right-handed neutrino masses of $O(10)$ TeV in the present model.
