Self-administered Phyto-acupressure for sleep disorders: a pilot study

Abstract

Objectives: To determine whether sleep quality in patients with sleep disorders is improved by Phyto-acupressure.

Design: YLO SOM is a prospective, observational 28 days pilot study with pre- and post-procedural measures and a self-recorded diary. Sleep onset latency, wake-up quality, early starts, awakenings and overall sleep quality were measured by numerical analogue scales.

Setting/location: The procedure was carried out across a large metropolitan area.

Subjects: A total of 25 patients (mean age 37 years) with sleep disorders without severe comorbidities took part.

Procedures: A home-based phyto-acupressure procedure, three times a day for 28 days was carried out.

Outcome measures: efficacy, safety, acceptability, compliance with home program, before, at the end, and during the trial (diary).

Findings: All patients followed the protocol correctly. No adverse effects were reported; therefore the skin tolerance of the device was very good. The use enabled a significant increase in overall sleep (+73% at the fourth week) and wake-up quality (+102% at W4). Issues with getting to sleep, the occurrence of night-time waking, early morning waking, as well as restless sleep were also vastly improved.

Conclusions: The results of this observational pilot study suggest that Phyto-acupressure is an effective and safe procedure for adult patients with sleep disorders that merit thorough evaluation through a randomized controlled trial.

Keywords: acupressure, Phyto-acupressure, self-administered acupressure, sleep disorders, traditional Chinese medicine, patient satisfaction, complementary medicine, integrative medicine, herbal medicine

Background

Twenty to thirty percent of the French population suffer with a sleep disorder. There are numerous disadvantages to existing drug-based solutions: dependence, difficulty waking up and poor quality of alertness during the day. YLO SOM is a Phyto-acupressure product to be used externally, specifically for sleep disorders. YLO SOM is available in the form of an acupressure pen containing an active plant concentrate (Angelica sinensis, Albizia julibrissin, Paeonia Albiflora, Eleutherococcus Senticosus). The aim of this study is to evaluate efficacy for sleep disorders, skin tolerance, as well as comfort of use of YLO SOM.

Materials and methods

The subjects

This is an open-label, intra-individual pilot study on 25 volunteer subjects (mean age of 37 years), presenting with common sleep disorders with no comorbidities for at least four months. Of the subjects included, 96% presented with night-time waking, 84% presented with early morning waking and restless sleep, and lastly 80% had difficulties falling sleep (sleep onset latency). The subjects did not receive any other sleep disorder treatment, and did not have any addictions, to either alcohol or drugs for example. The patients had to carefully follow the initial instructions given by the advising doctor.

Study design

The duration of the study was 28 days. The subjects needed to use YLO SOM three times per day. There are three steps to YLO SOM application: location of specific acupressure points, based on the sleep disorder; application of the active plant concentrate to these points with a roll-on applicator; activation of these points with acupressure using the stainless-steel tip of the pen. Location of the points could be carried out using the paper leaflet or via the smartphone app. The active plant concentrate contained root extracts of Angelica Sinensis, Paeonia Albitiflora, Eleutherococcus Senticosus and Albizia Julibrissin flower extract. Three different types of questionnaires were completed: the REC questionnaire, completed on the day of inclusion; the DD questionnaire, completed each day and the ACC questionnaire, completed at the end of the study. The study was conducted according to the following design (Figure 1).

Evaluation of tolerance

On D0, an evaluation of the condition of the skin was carried out by a doctor. On D28, a double evaluation of tolerance by the doctor and by the volunteers was performed. Any sign observed by the investigator or reported by the subjects was considered to be a potential adverse effect. This adverse effect needed to be attributable to the product.
Figure 1 Study design regarding the tolerance, efficacy and comfort of use of Ylo SOM.

Evaluation of efficacy on sleep quality, wake-up quality and sleep disorder symptoms

The subjects evaluated various parameters: sleep quality, wake-up quality, difficulties in falling asleep, night-time waking, early morning waking and restless sleep using a numerical scale from 1 (very poor or no improvement) to 10 (excellent or very strong improvement). This evaluation was made at the time of recruitment on D0 using the REC questionnaire, then daily for 28 days using the DD questionnaire for overall sleep quality and overall waking quality. The results were compiled on a weekly basis: W1, W2, W3 and W4. The results show the mean score obtained on D0, W1, W2, W3 and W4 for overall sleep quality and overall wake-up quality and the mean score obtained on D1 (improvement seen following the first use of Ylo SOM), W1, W2, W3 and W4 for difficulties in falling asleep, night-time waking, early morning waking and restless sleep.

Changes in emotional state of the patients

Sleep quality may have an impact on emotional state and to a wider extent on quality of life. The subjects evaluated the following eight emotional states on D0 (REC questionnaire) and again on D28 (ACC questionnaire) using a numerical scale from 1 (not at all) to 10 (very high): stress, nervousness, anxiety, sadness, fatigue, enthusiasm, relaxation and calmness. The mean score was calculated for all subjects on D0 and D28.

Evaluation of comfort, ease of use and convenience

At the end of the study, the subjects recorded their level of satisfaction with regards to the comfort, ease of use and convenience of Ylo SOM.

Statistical analyses

Statistical analyses were carried out using IBM SPSS Statistic 22 software and the Wilcoxon test. Statistical significance was defined as *p<0.05, **p<0.01 and *** if p<0.001.

Results

Evaluation of the efficacy for sleep quality, wake-up quality and alertness

A significant increase in sleep quality of +27% after one week, +62% after 2 weeks and +73% after 4 weeks was observed, as well as for wake-up quality, with +52% at one week, +88% after 2 weeks and +102% after 4 weeks. Improvement in sleep and wake-up quality increased the longer Ylo SOM was used (Figure 2). Sleep quality and wake-up quality are improved after using Ylo SOM.

Evaluation of the efficacy on sleep disorder symptoms

A significant improvement in all symptoms was observed. This improvement gradually increased, the more the product is used (Figure 3). After two weeks’ use, 100% of subjects felt there was an improvement.
improvement; for 20.8% this was from the third day, for 33%, from the first week and for 46%, from the second week.

**Evaluation of tolerance**

No adverse effects were reported, and therefore the skin tolerance of Ylo SOM was very good.

**Evaluation of comfort, ease of use and convenience**

Of the subjects included, 95.6% found Ylo SOM pleasant or very pleasant to use. Regarding ease of use, 83% of subjects found the protocol easy to understand and 87.5% found the duration of application acceptable. Locating the acupressure points was easy for 67% and moderately easy for 29%.

**Discussion**

Acupressure is commonly used in some cultures and countries to manage symptoms. This technique is non-invasive and has proven to be a useful solution for a wide variety of symptomatic patients. We are reporting on a device that combines acupressure and the cutaneous application of plant extracts to acupressure points. There are some studies reporting a similar procedure. Phyto-acupressure or the application of a herbal preparation on acupressure points is first mentioned in the Wu Shi Er Bing Fang, “recipes for 52 ailments” and is still very popular in China, especially in the prevention and treatment of allergic rhinitis.

We are reporting on an uncontrolled pilot study of phyto-acupressure in patients with insomnia. The acupressure points used for this trial are listed in Appendix 1. Shenmen (HT7), the most widely used acupressure point in existing treatment protocols for sleep disorders, was used in all our protocols. Additional acupressure points were selected according to the predominant sleep disorder presented.

Plants were selected based on their use in traditional Chinese medicine. The topical application of medicinal plant-based preparations to acupressure points currently uses a paste or cataplasm to treat different diseases in a wide range of Chinese clinical departments. The most common indications are for asthma, cough, abdominal pain, facial paralysis and constipation in internal medicine departments, for cough, asthma and diarrhea in pediatrics departments, for lumbar-sciatic pain in surgical departments, for rhino-sinusitis in ENT departments and for dysmenorrhea in gynecology departments. The main plants used in Ylo SOM were selected for their properties and their affinity with the meridians.

The Ylo SOM device decreases early morning waking, nighttime waking, sleep onset latency and self-perceived sleep quality. High compliance toward acupressure was observed. No localised side effects at the acupressure points, general side effects or negative feelings were reported during the four weeks of everyday use.

The biomedical model for acupressure is not yet fully established. It is thought that the mechanism of action involves direct stimulation of the interstitial fluid and connective tissue, functional peripheral and central nervous system changes, plus changes in the circulation of cytokines and neurotransmitters. The effects of acupressure on sleep quality may be attributed to the activation of the parasympathetic nervous system, an increase in autonomous response and a reduction in psychological stress. A reduction in stress was also observed in our study.

The extent of the effect is disproportionally high compared with the usual placebo effect observed in controlled trials. Other factors that may be deemed to be relevant include the information provided and discussed prior to inclusion, the use of a smart phone app during the trial and self-administration of treatment. These methodological bias may have affected the evaluation of the intrinsic efficacy of the device, however the overall assessment of the procedure represents true-life conditions and the actual effect on patient satisfaction. This trial provides several indications suggesting that this device has a potential to improve self-perceived sleep quality without any adverse effects. The procedure is easy to learn, non-invasive, and can be self-administered. Future controlled studies are required to investigate the inherent efficacy of the device and to monitor the effectiveness in minority populations with insomnia: children, pregnant women, chronic renal failure patients, residents in long-term care facilities.

Conclusion

The results of this observational pilot study suggest that Phyto-acupressure is an effective and safe procedure for adult patients with sleep disorders that merit thorough evaluation through a randomized controlled trial.

Acknowledgments

None.
