Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
First report of post-transplant autoimmune hepatitis recurrence following SARS-CoV-2 mRNA vaccination

ABSTRACT
Whilst vaccination for the SARS-CoV-2 virus has been successful in reducing the severity and burden of the COVID-19 pandemic, there have been recent reports of mRNA vaccines triggering autoimmune hepatitis in the native liver. There have been no descriptions thus far of recurrent ‘autoimmune hepatitis’ following liver transplantation in the context of SARS-CoV-2 vaccination. We describe a patient transplanted for autoimmune hepatitis who was stable for many years until they had immune-mediated flares coinciding with Pfizer-BioNTech mRNA vaccination. Intravenous steroid treatment was required to suppress histologically evident interface hepatitis. We firmly believe that mRNA vaccination was responsible for this ‘recurrence’ and that clinicians should be vigilant for this reaction in patients transplanted for autoimmune hepatitis.

Dear Editor

Whilst vaccination for the SARS-CoV-2 virus has been successful in reducing the severity and burden of the COVID-19 pandemic, there have been recent reports of mRNA vaccines triggering autoimmune hepatitis in the native liver [1]. There have been no descriptions thus far of recurrent ‘autoimmune hepatitis’ following liver transplantation in the context of SARS-CoV-2 vaccination. We describe a patient transplanted for autoimmune hepatitis who subsequently had immune-mediated flares coinciding with Pfizer-BioNTech mRNA vaccination.

A 32 year old woman of European origin underwent elective orthotopic liver transplantation for autoimmune hepatitis in 2014 with a donor following brainstem death. She was being maintained on conventional immunosuppression in the form of tacrolimus (Prograf 4 mg mane, 3 mg nocte), azathioprine 50 mg daily and prednisolone 5 mg daily. In addition, she was prescribed aspirin 75 mg daily, vitamin D supplementation and atenolol 50 mg daily for hypertension. From 2015 onwards her ALT remained broadly in the normal range apart from recurrent mild rise in ALT to 62 U/L following which the azathioprine dose was reduced to 10 mg daily at that visit with subsequent higher dose oral prednisolone (20 mg daily). Her liver biochemistry normalised and her ALT was 30 U/L on 15 mg prednisolone at subsequent outpatient review end of January 2022. The prednisolone dose was reduced to 10 mg daily at that visit with subsequent mild rise in ALT to 62 U/L following which the azathioprine dose was increased to 75 mg daily and the ALT was seen to normalise again (Fig. 2). On further questioning, the patient reported having her third Pfizer-BioNTech vaccine on 20 November 2021, approximately 3 weeks before her initial ALT rise. Retrospectively, she was noted to have had an ALT spike of 85 U/L on 20 May 2021 having had her second Pfizer-BioNTech vaccination on 24 April 2021. Her initial Pfizer-BioNTech...
vaccine was on 30 January 2021 and she received a recent ‘booster’ dose of Pfizer-BioNTech vaccine on 5 March 2022.

In summary, we report hitherto undescribed post-transplant ‘recurrent autoimmune’ hepatitis associated temporally with mRNA vaccination for the SARS-CoV-2 virus. It is suggested that mRNA vaccines can result in molecular mimicry leading to autoimmune phenomena, via upregulation of specific immunological pathways [2]. The lack of alternative explanation as well as the ALT spike observed after her second vaccination are supportive. ALT values are lacking during the aftermath of her first dose so it is unknown whether any ALT flare occurred then. The lack of ALT rise after her fourth dose may be explained by additional immunosuppression and lower dose volume of a ‘booster’ rather than full vaccine. We suggest that transplant clinicians monitor for the possibility of ALT flares in ‘primed’ liver transplant recipients after SARS-CoV-2 mRNA vaccination; early recognition and prompt intervention may reduce morbidity from this potential side-effect.

Fig. 1. A) x100 hematoxylin and eosin stain showing portal inflammatory infiltrate composed predominantly of lymphocytes, also with plasma cells and rare eosinophils. There is interface activity with focal rosetting and emperipolesis. There is also adjacent lobular inflammation with scattered acidophilic bodies. Portal vein endothelialitis is mild and focal. B) x200 hematoxylin and eosin stain showing terminal hepatic vein lymphohistiocytic inflammation with a rare acidophilic body but little endothelialitis.

Fig. 2. Graph showing ALT course over 2021 into 2022. The arrows (red) show the time points for each administration of Pfizer-BioNTech SARS-CoV-2 vaccine. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
