Abstract

The relativistic “no pair” model of quantum electrodynamics uses the Dirac operator, $D(A)$ for the electron dynamics together with the usual self-energy of the quantized ultraviolet cutoff electromagnetic field $A$ — in the Coulomb gauge. There are no positrons because the electron wave functions are constrained to lie in the positive spectral subspace of some Dirac operator, $D$, but the model is defined for any number, $N$, of electrons, and hence describes a true many-body system. In addition to the electrons there are a number, $K$, of fixed nuclei with charges $\leq Z$. If the fields are not quantized but are classical, it was shown earlier that such a model is always unstable ($E = -\infty$) if one uses the customary $D(0)$ to define the electron space, but is stable ($E > -\text{const.}(N+K)$) if one uses $D(A)$ itself (provided the fine structure constant $\alpha$ and $Z$ are not too large). This result is extended to quantized fields here, and stability is proved for $\alpha = 1/137$ and $Z \leq 42$. This formulation of QED is somewhat unusual because it means that the electron Hilbert space is inextricably linked to the photon Fock space. But such a linkage appears to better describe the real world of photons and electrons.

1 Introduction

The theory of the ground state of matter interacting with Coulomb forces and with the magnetic field is not yet in a completely satisfactory state. Open problems remain, such as the inclusion of relativistic mechanics into the many-body formalism and the inclusion of the self-energy effects of the radiation field, especially the quantized radiation field.
One of the fundamental attributes of quantum mechanics is the existence of a Hamiltonian with a lowest, or ground state energy, and not merely the existence of a critical point of a Lagrangian. The ‘stability’ problem, which concerns us here, is to show that the ground state energy is bounded below by a constant times the total number of particles, \( N + K \), where \( N \) is the number of electrons and \( K \) is the number of nuclei – whose locations, in this model, are fixed, but chosen to minimize the energy. We do not discuss the existence of a normalizable ground state eigenfunction, as in \[8\], but only the lower boundedness of the Hamiltonian.

This problem has been resolved successfully in various models such as the usual nonrelativistic Schrödinger Hamiltonian with only electrostatic interactions. Further developments include extensions to relativistic kinetic energy \( \sqrt{p^2 + m^2} - m \) in place of the nonrelativistic \( p^2/2m \), and extensions to matter interacting with classical magnetic fields (including a spin-field interaction \( B \)), stabilized by the classical field energy
\[
\frac{1}{8\pi} \int B(x)^2 \, dx ,
\] (1)
and then the quantization of the \( B \) field. Many people participated in this development and we refer the reader to \[17\] and the references therein for an account up to 1997.

In this paper we take a further step by addressing the problem of relativistic matter, using the Dirac operator (without pair production, i.e., the “no-pair” model) interacting with the quantized radiation field having an ultraviolet cutoff \( \Lambda \). In \[17\] the corresponding problem was solved with a classical radiation field, in which the field energy is given by \((1)\), and we shall use some of the ideas of that paper here. The idea for such a model goes back to \[3\] and \[23\]. With a classical \( B \) field no ultraviolet cutoff is needed, but it is needed with a quantized field, for otherwise the field energy diverges.

Because of the ultraviolet cutoff our model, which in other respects is relativistic, is not truly relativistic at energies of the order of the cutoff. We have not, however, attempted to renormalize the theory and, if this can be done consistently, the resulting theory will be relativistic at all energies.

In \[4\] the problem of nonrelativistic electrons (with spin) interacting with the quantized ultraviolet cutoff field was solved by using results in \[16\] but using only the part of the field energy within a distance \( 1/\Lambda \) of the fixed nuclei. The constants and exponents in \[4\] were improved in \[7\]; in particular, the Hamiltonian is bounded below by \(-\Lambda K\). The relation of the classical field energy to the quantized field energy involves a commutator that, when integrated over the whole space \( \mathbb{R}^3 \) yields an infinite constant, even with an ultraviolet cutoff. This is the reason for considering only a local field energy, since only a local field energy yields a finite commutator, and we do the same here.

In Section \[2\] our model is defined and the main Theorem \[2.1\] is stated. With the fine structure constant \( \alpha = 1/137 \), stability holds for \( Z \leq 42 \). The main idea of the “no-pair” model is that
there are no positrons, and electronic wave functions are allowed to lie only in the positive spectral subspace of some Dirac operator $D$. While the Dirac operator $D(A)$, which is contained in the Hamiltonian and which defines the electron dynamics, always contains the magnetic vector potential $A(x)$, the operator $D$ that defines an electron could be $D(0)$, the free Dirac operator. Indeed, this is the conventional choice, but it is not gauge invariant and always leads to instability as first shown in [17] for classical fields and here for quantized fields.

The question of instability is complicated. There are two kinds (first and second) and two cases to consider (with and without Coulomb potentials). Instability of the first kind means that the ground state energy (bottom of the spectrum of the Hamiltonian) is $-\infty$. Instability of the second kind means that the energy is finite but is not bounded below by a constant times $N + K$. The occurrence of these instabilities may or may not depend on $\alpha$ and $Z$ and whether or not a cutoff $\Lambda$ is present.

The physical nature of the instability, if it occurs, is different in the two cases. When it occurs in the absence of Coulomb potentials (meaning that the $\alpha V_c$ term in (11) is omitted) it is due to the $\sqrt{\alpha} A(x)$ term in $D(A)$ blowing up. When it occurs because of the Coulomb potentials being present it is due to an electron falling into the Coulomb singularity of the nucleus. The various possibilities, all proved in this paper, are summarized in detail in the following two tables and discussed in detail in Appendix E. For the proofs of the instabilities listed here, we rely heavily on [17] and [9].

**Electrons defined by projection onto the positive subspace of $D(0)$, the free Dirac operator**

| Classical or quantized field without cutoff $\Lambda$ $\alpha > 0$ but arbitrarily small. | Classical or quantized field with cutoff $\Lambda$ $\alpha > 0$ but arbitrarily small. |
|---|---|
| **Without Coulomb potential $\alpha V_c$** | Instability of the first kind | Instability of the second kind |
| **With Coulomb potential $\alpha V_c$** | Instability of the first kind | Instability of the second kind |
Electrons defined by projection onto the positive subspace of $D(A)$, the Dirac operator with field

| Without Coulomb potential $\alpha V_c$ | Classical field with or without cutoff $\Lambda$ or quantized field with cutoff $\Lambda$ |
|----------------------------------------|-------------------------------------------------------------------------------------------|
| With Coulomb potential $\alpha V_c$   | The Hamiltonian is positive                                                                |
|                                        | Instability of the first kind when either $\alpha$ or $Z\alpha$ is too large             |
|                                        | Stability of the second kind when both $\alpha$ and $Z\alpha$ are small enough            |

The main point of this paper is the proof of the bottom row of the second table in the quantized case; the classical case was done in [17].

There are several ways in which one could hope to go further. One is that one should really prove stability for the binding energy, i.e., one should compute the energy difference between that of free particles and that of the interacting system. In a theory with quantized fields the self-energy, i.e., the energy of a free electron, is unknown and quite large. As we show in [13] and [14] the self-energy of a nonrelativistic particle with spin is bounded below by $+\Lambda$, and probably even $+\Lambda^{3/2}$. Moreover, for $N$ fermions (but not for bosons) this energy is proportional to $C'N\Lambda$ with $C' > 0$.

Another very important problem to consider is renormalization; our mass $m$ is the unrenormalized one. An answer to this problem also has to address the question of the meaning of mass in an ultraviolet cut-off model, since several definitions are possible. Is it the coefficient of $\beta$ in an effective Dirac operator that gives the renormalized dynamics, or is it the ground state energy of a “free” electron?

The results in this paper will be used in another paper of ours [15] to give upper bounds to the hydrogen atom binding energy (and hence to the mass renormalization using the first definition) in this relativistic no-pair model and in some non-relativistic models with quantized fields.

Finally, let us note that the inclusion of positrons into the model cannot change the fact that defining an electron by means of $D(0)$ will still cause the instabilities listed in the tables above. The reason is simply that the existence of positrons does not prevent one from considering states consisting purely of electrons, and these alone can cause the listed instabilities.

The use of $D(A)$ instead of $D(0)$ to define the electron requires a significant change in the Hilbert space structure of QED. It is no longer possible to separate the Hilbert space for the electron coordinates from the Hilbert space (Fock space) of the photons. The two are now linked in a manner that we describe in the next section.
2 Basic Definitions

We consider $N$ relativistic electrons in the field of $K$ nuclei, fixed at the positions $R_1, ..., R_K \in \mathbb{R}^3$. (In the real world the fixed nuclei approximation is a good one since the masses of the nuclei are so large compared to the electron’s mass.) We assume that their atomic numbers $Z_1, ..., Z_K$ are all less than some fixed number $Z > 0$. Since the energy is a concave function of each $Z_j$ separately, it suffices, for finding a lower bound, either to put $Z_j = 0$, i.e., to remove the $j$-th nucleus, or to put $Z_j = Z$ (see [5]). Thus, without loss of generality, we may assume that all the nuclear charges are equal to $Z$.

We use units in which $\hbar = 1$ and $c = 1$. $\alpha = e^2/\hbar c$ is the dimensionless “fine structure constant” (=1/137 in nature). The electric charge of the electron in these units is $e = \sqrt{\alpha}$.

We use the Coulomb, or radiation gauge so that the Coulomb potential is a function only of the coordinates of the $N$ electrons, $x_1, x_2, \ldots, x_N$ and equals $\alpha V_c$, where

$$V_c = -Z \sum_{i=1}^{N} \sum_{k=1}^{K} \frac{1}{|x_i - R_k|} + \sum_{1 \leq i < j \leq N} \frac{1}{|x_i - x_j|} + Z^2 \sum_{1 \leq k < l \leq K} \frac{1}{|R_k - R_l|}.$$  \hspace{1cm} (2)

In this gauge, it is the vector potential that is quantized. A careful discussion of the field and its quantization is given in Appendix A. The (ultraviolet cutoff) magnetic vector potential is defined by

$$A(x) = \frac{1}{2\pi} \sum_{\lambda=1}^{2} \int_{|k| \leq \Lambda} \frac{\varepsilon_{\lambda}(k)}{\sqrt{\omega(k)}} \left( a_{\lambda}(k)e^{ik\cdot x} + a_{\lambda}^*(k)e^{-ik\cdot x} \right) dk,$$  \hspace{1cm} (3)

where $\Lambda$ is the ultraviolet cutoff on the wave-numbers $|k|$. The operators $a_\lambda, a_\lambda^*$ satisfy the usual commutation relations

$$[a_{\lambda}(k), a_{\nu}^*(q)] = \delta(k - q)\delta_{\lambda,\nu} , \quad [a_{\lambda}(k), a_{\nu}(q)] = 0, \quad \text{etc}$$  \hspace{1cm} (4)

and the vectors $\varepsilon_{\lambda}(k)$ are the two possible orthonormal polarization vectors perpendicular to $k$ and to each other.

Our results hold for all finite $\Lambda$. The details of the cutoff in (3) are quite unimportant, except for the requirement that rotation symmetry in $k$-space is maintained. E.g., a Gaussian cutoff can be used instead of our sharp cutoff. We avoid unnecessary generalizations. The cutoff resides in the $A$-field, not in the field energy, $H_f$, sometimes called $d\Gamma(\omega)$, which is given by

$$H_f = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} \omega(k)a^*_{\lambda}(k)a_{\lambda}(k)dk$$  \hspace{1cm} (5)

The energy of a photon is $\omega(k)$ and the physical value of interest to us, which will be used in the rest of this paper, is

$$\omega(k) = |k|$$  \hspace{1cm} (6)
Again, generalizations are possible, but we omit them.

An important fact for our construction of the physical Hilbert space of our model is that $[A(x), A(y)] = [B(x), B(y)] = [A(x), B(y)] = 0$ for all $x, y$. Here, $B$ is the magnetic field given by

$$B(x) = \text{curl} A(x) = \frac{i}{2\pi} \sum_{\lambda=1}^{2} \int_{|k| \leq \Lambda} \frac{k \wedge \epsilon(k)}{\sqrt{\omega(k)}} \left( a_{\lambda}(k)e^{ik \cdot x} - a^{*}_{\lambda}(k)e^{-ik \cdot x} \right) dk .$$

(7)

The kinetic energy of an electron is defined in terms of a Dirac operator with the vector potential $A(x)$ (with $x$ being the electron’s coordinate)

$$D(A) := \alpha \cdot (-i \nabla + \sqrt{\alpha}A(x)) + m\beta ,$$

(8)

with $\alpha$ and $\beta$ given by the $2 \times 2$ Pauli matrices and $2 \times 2$ identity $I$ as

$$\alpha = \begin{pmatrix} 0 & \sigma \\ \sigma & 0 \end{pmatrix}, \quad \beta = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} .$$

Note that

$$D(A)^2 = \tilde{T}^{P}(A)(A) + m^2 ,$$

(9)

where $\tilde{T}^{P}(A) = \begin{pmatrix} T^{P}(A) & 0 \\ 0 & T^{P}(A) \end{pmatrix}$ and $T^{P}(A)$ is the Pauli operator on $L^{2}(\mathbb{R}^3; \mathbb{C}^2)$,

$$T^{P}(A) = \left[ \sigma \cdot (p + \sqrt{\alpha}A(x)) \right] = (p + \sqrt{\alpha}A(x))^2 + \sqrt{\alpha} \sigma \cdot B(x) .$$

(10)

As a step towards defining a physical Hamiltonian for our system of $N$ electrons and $K$ fixed nuclei, we first define a conventional, but fictitious Hamiltonian

$$H'_{N} = \sum_{i=1}^{N} D_{i}(A) + \alpha V_{c} + H_{f} .$$

(11)

This $H'_{N}$ acts on the usual Hilbert space $\mathcal{H}_{N} = \bigotimes^{N} L^{2}(\mathbb{R}^3; \mathbb{C}^4) \bigotimes \mathcal{F}$, where $\mathcal{F}$ is the Fock space for the $A$-field. A vector in $\mathcal{H}_{N}$ can be written

$$\Psi = \bigoplus_{j=0}^{\infty} \Phi_{j}(x_1, ..., x_N; \tau_1, ..., \tau_N; k_1, ..., k_j; \lambda_1, ..., \lambda_j) .$$

(12)

Here, the $\lambda_i$ take the two values 1, 2 and the the $\tau_i$ take the four values 1, 2, 3, 4. Each $\Phi_j$ is symmetric in the pairs of variables $k_i, \lambda_i$ and it is square integrable in $x, k$. The sum of these integrals (summed over $\lambda$’s, $\tau$’s, and $j$) is finite. The operators $a_{\lambda}(k)$ and their adjoints act, as usual, by

$$a_{\lambda}(k)\Psi = \bigoplus_{j=0}^{\infty} \sqrt{j + 1} \Phi_{j+1}(x_1, ..., x_N; \tau_1, ..., \tau_N; k_1, ..., k_j, k; \lambda_1, ..., \lambda_j, \lambda) .$$

(13)
As mentioned before, the physical Hilbert space is constructed using the positive spectral projections of the Dirac operators $D_i(A)$. By Lemma C.1 the $N$ Dirac operators commute in the strong sense that their spectral projections commute with each other. Thus, the Hilbert space $\mathcal{H}_N$ can be divided into $2^N$ subspaces according to the positive and negative spectral subspaces of each $D_i(A)$. (Note that as long as $m > 0$ there is no zero spectral subspace.) We denote by $P^+$ the orthogonal projection onto the positive spectral subspace for all the Dirac operators.

The space $P^+\mathcal{H}_N$ is invariant (up to unitary equivalence) by the natural action of the permutation group $S_N$ consisting of permutations of the electron labels. In accordance with the Pauli principle we choose the antisymmetric component of $P^+\mathcal{H}_N$, as the physical Hilbert space. Thus, our physical Hilbert space is given as

$$\mathcal{H}_N^{\text{phys}} = A P^+ \mathcal{H}_N$$

(14)

where $A$ is the projector onto the antisymmetric component.

Formally, i.e., without attention to domain questions, our physical Hamiltonian on $\mathcal{H}_N^{\text{phys}}$ is defined to be

$$H_N^{\text{phys}} = P^+ H_N' P^+.$$  

(15)

Since we are interested in this operator as a quadratic form, it suffices to specify a domain $Q_N$ which is dense in $\mathcal{H}_N^{\text{phys}}$ and on which the expectation values of the all the operators involved are finite. Since all the operators are symmetric, and since a stability estimate entails that the quadratic form is bounded below, its closure exists and defines a selfadjoint operator $H_N^{\text{phys}}$. Such a domain $Q_N$ is constructed in Appendix D. Note that by definition $Q_N$ consists of antisymmetric elements.

We note that each of the $N$ Dirac operators commute with $P^+$. For $\psi \in Q_N$ we have $D_i(A)\psi = P^+ D_i(A)\psi$. For the other two terms in (11) the role of the projector is not so trivial and that is why we have to write $P^+ H_N' P^+$.

This model has its origins in the work of Brown and Ravenhall [3] and Sucher [23]. The immediate antecedent is [17].

Let us note five things:

(i). It is not entirely easy to think about $\mathcal{H}_N^{\text{phys}}$ because the electronic $L^2$-spaces and the Fock space are now linked together. In our choice of positive energy states, the electrons have their own photon cloud. We chose to apply the projector $P^+$ first and then antisymmetrize. As explained in Appendix D we can, of course, do it the other way around and obtain the same Hilbert space, since $P^+$ commutes with permutations. We also show in Appendix D that $\mathcal{H}_N^{\text{phys}}$ is not trivial; in fact it is infinite dimensional.

(ii). Usually, in quantum electrodynamics, one defines $\mathcal{H}_N^{\text{phys}}$ by means of the positive spectral subspace of the free Dirac operator $D(0) = -i\alpha \cdot \nabla + m\beta$, instead of $D(A)$. This is easier to think
about but, as demonstrated in [17] with a classical $A$ field instead of a quantized field, the choice of $D(0)$ always leads to instability, as listed in the tables in Section 1 and discussed in detail in Appendix E.

(iii). Because of the restriction to the positive spectral subspace of $D(A)$, the Dirac operator is never negative. The only negative terms in $H_{N}^{\text{phys}}$ come from the Coulomb potential. It should also be noted that the choice of the free Dirac operator to define an electronic wave function is not a gauge covariant notion. The $D(A)$ choice is gauge covariant.

(iv) $H_{N}^{\text{phys}}$ depends on $\alpha$ and $m$.

(v) While energy, being one component of a four-vector, is not a relativistically invariant quantity, it is true, nevertheless, that positive and negative energies of $D(A)$ are relativistic concepts since they are invariant under Lorentz transformations that do not change the direction of time.

We thank J-M. Graf for this remark and we thank J. Yngvason for noting that for this to be true it is essential that the joint spectrum of energy and momentum of $D(A)$ lies in the light cone. We have not proved this, but it is plausibly true.

Our main result, to be proved in Section 2.1, is

2.1. THEOREM (Relativistic Quantum electrodynamic Stability). Assume that $Z$ and $\alpha$ are such that there is a solution $\kappa$ and $\varepsilon \geq 0$ to the three inequalities (52), (53) and (54). Then $H_{N}^{\text{phys}}$ in (15) is bounded below by

\[ H_{N}^{\text{phys}} \geq +\sqrt{\varepsilon} mN - \frac{18\Lambda}{\pi} KC^{3}_{2}, \]

where

\[ C^{4}_{2} = \frac{N}{K} \frac{6\sqrt{1-\varepsilon} + (\alpha/2)(\sqrt{2Z} + 2.3)^{2}}{27/2\pi}. \]

In particular, $Z \leq 42$ is allowed when $\alpha = 1/137$.

Actually, our proof of Theorem 2.1 utilizes the absolute value of the Dirac operator $|D(A)|$ on the Hilbert space $A\mathcal{H}_{N}$. If we recall the connection between $D(A)$ and the Pauli operator in (11) and (10), we can prove the following theorem as a byproduct of our proof of Theorem 2.1. Note $C^{2}$ in place of $C^{4}$ here.

2.2. THEOREM (Stability with the Pauli operator). Let $H_{N}^{\prime} = \sum_{i=1}^{N} \sqrt{T^{2}(A)} + m^{2} + \alpha V_{c} + H_{f}$ be a Hamiltonian on the space $A \otimes^{N} L^{2}(\mathbb{R}^{3}; C^{2}) \otimes \mathcal{F}$. Then stability of the second kind holds under the conditions stated in Theorem 2.1, and with the same lower bound (16).

3 Bounding the Coulomb Potential by a Localized Relativistic Kinetic Energy

The following Theorem 3.1 contains the main technical estimate needed in this paper, but it is independently interesting. It deals with a model of relativistic electrons interacting with quantized
fields, but without the spin-field interaction and without the field energy. While this model is different from the no-pair Hamiltonian (13), some of its properties will be useful later. We consider two such Hamiltonians: A usual one

\[ \kappa \sum_{i=1}^{N} |p_i + \sqrt{\alpha} A(x_i)| + V_c , \quad (18) \]

(with \( \kappa > 0 \)) and a related one with a localized kinetic energy described below in (24), (25). In this section \( A(x) \) is some given classical field, not necessarily divergence free. There is no \( \alpha \) in front of \( V \) in (18). The Hilbert space is \( \mathcal{A} \otimes \mathcal{N} L^2(\mathbb{R}^3; \mathbb{C}^q) \) for fermions with \( q \) ‘spin states’.

With the \( K \) nuclei positioned at distinct points \( R_j \in \mathbb{R}^3 \), for \( j = 1, \ldots, K \), we define the corresponding Voronoi cells by

\[ \Gamma_j = \{ x \in \mathbb{R}^3 : |x - R_j| < |x - R_i|, i = 1, \ldots, K, i \neq j \} . \quad (19) \]

These Voronoi cells are open convex sets. We choose some \( L > 0 \) and define the balls \( B_j \subset \mathbb{R}^3 \) by

\[ B_j = \{ x : |x - R_j| \leq 3L \} , \quad (20) \]

and denote by \( \mathcal{B} \) the union of these \( K \) balls and by \( \chi_{\mathcal{B}} \) the characteristic function of \( \mathcal{B} \). Similarly, we define smaller balls, \( \mathcal{S}_j = \{ x : |x - R_j| \leq 2L \} \), and define \( \chi_{\mathcal{S}} \) to be the characteristic function of the union of these \( K \) smaller balls. Choose some function \( g \in W^{1,1}(\mathbb{R}^3) \) with support in \( \{ x : |x| \leq 1 \} \), with \( g \geq 0 \) and with \( \int g = 1 \). Define \( g_L(x) = L^{-3} g(x/L) \). Clearly \( \int g_L = 1 \) and \( g_L \) has support in \( \{ x : |x| \leq L \} \). With \( \ast \) denoting convolution, set

\[ \phi_1(x) = g_L \ast \chi_{\mathcal{S}}(x) . \quad (21) \]

This function \( \phi_1 \) is nonnegative and everywhere bounded by 1. We also define \( \phi_2 = 1 - \phi_1 \) and set

\[ F = \phi_1 / \sqrt{\phi_1^2 + \phi_2^2} , \quad G = \phi_2 / \sqrt{\phi_1^2 + \phi_2^2} . \quad (22) \]

Note that \( \phi_1^2 + \phi_2^2 \geq 1/2 \) and \( F(x) = 1 \) if \( |x - R_j| < L \) for some \( j \). Note also that \( F \) and \( \phi_1 \) are supported in \( \mathcal{B} \), i.e., \( \chi_{\mathcal{B}} \phi_1 = \phi_1 \) and \( \chi_{\mathcal{B}} F = F \).

We find that

\[ |\nabla F|^2 + |\nabla G|^2 \leq 4|\nabla \phi_1|^2 \leq \frac{4}{L^2} \left( \int_{\mathbb{R}^3} |\nabla g(x)| dx \right)^2 . \quad (23) \]

and hence \( |\nabla F|, |\nabla G| \leq 2|\nabla \phi_1| \).

The function \( g \) that minimizes the integral in (23) is \( g(x) = 3/4\pi \) for \( |x| \leq 1 \) and zero otherwise. (Although this \( g \) is not in \( W^{1,1}(\mathbb{R}^3) \) it is a limit of \( W^{1,1}(\mathbb{R}^3) \) functions.) Then the integral equals 3 and \( |\nabla F|^2 + |\nabla G|^2 \leq 36L^{-2} \).

The localized kinetic energy operator \( Q(A) \) is given by

\[ Q(A) = F(x) |p + \sqrt{\alpha} A(x)| F(x) = F(x) \sqrt{(p + \sqrt{\alpha} A(x))^2} F(x) . \quad (24) \]
This operator is well defined as a quadratic form since the function $F$ is smooth, and hence defines a self-adjoint operator via the Friedrichs extension.

The related relativistic Hamiltonian, with localized kinetic energy, is now defined by

$$H_N^\text{loc} := \kappa \sum_{i=1}^{N} Q_i(A) + V_c,$$

and has the following bound which, it is to be noted, does not depend on the details of $g(x)$.

### 3.1. THEOREM (Bound on Coulomb energy).

For any vector field $A(x)$ and for $N$ fermions with $q$ spin states,

$$\kappa \sum_{i=1}^{N} Q_i(A) + V_c \geq -\frac{N}{2L} \max\{(\sqrt{2Z} + 1)^2, 2Z + \frac{110}{21}\} \geq -\frac{N}{2L} (\sqrt{2Z} + 2.3)^2,$$

provided $\kappa \geq \max\{q/0.031, \pi Z\}$.

**Proof.** It was proved in [19] (eqns. (2.4-2.6) with $\lambda = 10/11$) that the Coulomb potential $V_c$ is bounded below by a single-particle potential plus a constant, namely, for $x_i, R_j \in \mathbb{R}^3$,

$$V_c \geq -\sum_{i=1}^{N} W(x_i) + \frac{Z^2}{8} \sum_{j=1}^{K} \frac{1}{D_j},$$

where $2D_j = \min_{i \neq j}\{|x_i - x_j|\}$ and, for $x \in \Gamma_j$,

$$W(x) = \frac{(\sqrt{Z} + 1/\sqrt{2})^2}{|x - R_j|} \text{ for } |x - R_j| \geq \frac{10D_j}{11},$$

$$= \frac{Z}{|x - R_j|} + \frac{121}{42D_j} \text{ for } |x - R_j| < \frac{10D_j}{11}.$$ (27)

This estimate reduces our problem to finding a lower bound to

$$\kappa \sum_{i=1}^{N} Q_i(A) - \sum_{i=1}^{N} F(x_i)^2 W(x_i) - \sum_{i=1}^{N} (1 - F(x_i)^2) W(x_i) + \frac{Z^2}{8} \sum_{j=1}^{K} \frac{1}{D_j}.$$ (29)

Since $F(x) = 1$ if $|x - R_j| < L$ for some $j$, the third term in (29) is bounded below by

$$-\frac{N}{2L} \max\{(\sqrt{2Z} + 1)^2, 2Z + \frac{110}{21}\}.$$ (30)

Estimating the first and second terms using the Pauli exclusion principle amounts to filling the lowest possible energy levels with $q$ electrons each, and this energy is bounded below by $q$ times the sum of the negative eigenvalues of the operator

$$F(x)(|p + \sqrt{\alpha A(x)}| - W(x))F(x).$$ (31)

According to the generalized min-max principle [12] Corollary 12.2, and the fact that $\|F\psi\| \leq \|\psi\|$, this is bounded below by $q$ times the sum of the negative eigenvalues of the operator $|(p +
\[ \sqrt{\alpha A(x)} - W(x) \]. However, Theorem 1 of [19], shows that this sum is not less than \(-Z^2/8\sum_{j=1}^{K} 1/D_j\) under the stated condition on \(k\).

(Note: We refer here to Theorem 1 of [19] because, as noted in [17], the proof of that theorem holds for \(|p + \sqrt{\alpha A(x)}|\in place of \(|p|\). While Theorem 1 of [19] is stated in terms of \(V_c\), the proof in [19] actually replaces \(V_c\) by its lower bound (27).)

4 Proof of Theorem 2.1

We employ a strategy similar to that in [17].

As a first step we use Theorem 3.1 with a suitable choice of \(L\) to control the Coulomb potential.

The operators appearing in Theorem 3.1 do not involve spin, but the number of spin states, \(q\), is important for determining the relevant value of \(\kappa\). The correct choice is \(q = 2\), not \(q = 4\), as explained in [17] page 42 and appendix B. The point is the following. The one-body density matrix \(\Gamma(x,\sigma;x',\sigma')\) coming from an antisymmetric \(N\) particle wave function \(\Psi\) defines a reduced one body density matrix

\[ \gamma(x,x') = \sum_{\sigma=1}^{4} \Gamma(x,\sigma;x',\sigma) . \quad (32) \]

This reduced density matrix, in general, satisfies \(0 \leq \text{Tr} \gamma \equiv \int \gamma(x,x)dx \leq 4\). If, however, \(\Psi\) is in the range of \(P^+\), then \(0 \leq \text{Tr} \gamma \leq 2\), as shown in [17]. In the proof of Theorem 3.1, the only relevant information about \(\Psi\) enters via the reduced single particle matrix \(\gamma\). Thus, we require only \(\kappa \geq \max\{64.5, \pi Z\}\).

In the definition of \(F\) we set \(L = C_2/\Lambda\) where \(C_2 > 0\) is some constant to be conveniently chosen later. We then have (recalling (8), (10), and \(P^+D_i(A)P^+ = P^+|D_i(A)|P^+\))

\[ P^+ \left[ \sum_{i=1}^{N} D_i(A) + aV_c \right] P^+ \geq P^+ \sum_{i=1}^{N} \left[ \sqrt{T_i^P(A) + m^2 - \kappa \alpha Q_i(A)} \right] P^+ - \alpha N \frac{\Lambda}{2C_2} (\sqrt{2Z + 2.3})^2 P^+ . \quad (33) \]

(Here, \(Q(A)\) really denotes the \(4 \times 4\) operator \(Q(A) \otimes I_4\) where \(I_4\) is the identity in spin-space.)

Consider the operator

\[ H_2 := P^+ \sum_{i=1}^{N} \left[ \sqrt{T_i^P(A) + m^2 - \delta m - \kappa \alpha Q_i(A) + C_3 \Lambda} \right] P^+ , \quad (34) \]

where the numbers \(0 \leq \delta \leq 1\) and \(C_3 > 0\) will be chosen later.

If we denote by \(\Xi^+\) the projection onto the positive spectral subspace of \(D(A)\) acting on \(L^2(\mathbb{R}^3;C^4) \otimes \mathcal{F}\), then \(H_2\) is bounded below by

\[ \text{Tr}_4[\Xi^+ S \Xi^+]^- , \quad (35) \]
where $\text{Tr}_n$ with $n = 1, 2, 4$ denotes the trace on $L^2(\mathbb{R}^3; \mathbb{C}^n)$. The operator $S$ is
\[
S := \sqrt{T^P(A) + m^2 - \delta m - \kappa \alpha Q(A) + C_3 \Lambda}.
\]
(36)
It has the form
\[
S = \begin{pmatrix} Y & 0 \\ 0 & Y \end{pmatrix}.
\]
(37)
Here, the entry $Y$ is a $2 \times 2$ matrix valued operator and $[X]_-$ denotes the negative part of a self-adjoint operator $X$ (and which is nonnegative by definition). The projection $\Xi^+$ is not explicitly given, but observing, as in [17], that the projection $\Xi^-$ onto the negative energy states is related to $\Xi^+$ by
\[
\Xi^- = U^{-1} \Xi^+ U = -U \Xi^+ U,
\]
(38)
where $U$ is the matrix
\[
U = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},
\]
(39)
we see that the operators $\Xi^+ S \Xi^+$ and $\Xi^- S \Xi^-$ have the same spectrum. Thus,
\[
\text{Tr}_4[\Xi^+ S \Xi^+]_- \leq \frac{1}{2} \text{Tr}_4[S]_- = \text{Tr}_2 \left[ \sqrt{T^P(A) + m^2 - \delta m - \kappa \alpha Q(A) + C_3 \Lambda} \right]_-. \]
(40)
Therefore, the infimum of the spectrum of $H_2$ over states that satisfy the Pauli exclusion principle (with 4 spin states) is bounded below by
\[
-\text{Tr}_2 \left[ \sqrt{T^P(A) + m^2 - \delta m - \kappa \alpha Q(A) + C_3 \Lambda} \right]_-.
\]
(41)
The BKS inequality [2] (see also [17]) states that for positive operators $A$ and $B$, $\text{Tr}_2[A - B]_- \leq \text{Tr}_2[A^2 - B^2]_-^{1/2}$. Note that $\sqrt{T^P(A) + m^2 - \delta m} \geq 0$ and, therefore,
\[
H_2 \geq -\text{Tr}_2 \left[ \left( \sqrt{T^P(A) + m^2 - \delta m} + C_3 \Lambda \right)^2 - \kappa^2 \alpha^2 Q(A)^2 \right]_-^{1/2},
\]
(42)
which is greater than
\[
-\text{Tr}_2 \left[ \left( \sqrt{T^P(A) + m^2 - \delta m} \right)^2 + C_3^2 \Lambda^2 - \kappa^2 \alpha^2 Q(A)^2 \right]_-^{1/2}.
\]
(43)
(Here, and in the following, we use the fact that $\text{Tr}[X]_-^{1/2}$ is monotone decreasing in $X$.)
Next, we expand $(\cdots)^2$ in (43) and use the arithmetic-geometric mean inequality to bound (43) from below by
\[
-\text{Tr}_2 \left[ (T^P(A) + m^2)(1 - \varepsilon) + (1 - 1/\varepsilon)m^2 \delta^2 + C_3^2 \Lambda^2 - \kappa^2 \alpha^2 Q(A)^2 \right]_-^{1/2}.
\]
(44)
We choose \( \delta \) so that the mass disappears, i.e., \( \delta^2 = \varepsilon \).

The next step is to localize the Pauli term \( T^P(A) \). A standard calculation shows that (with \( F, G \) as in Section 3)

\[
T^P(A) = F T^P(A) F + G T^P(A) G - |\nabla F|^2 - |\nabla G|^2 \geq F T^P(A) F - |\nabla F|^2 - |\nabla G|^2 .
\]  

(45)

We insert the right side of (45) into (44) and, recalling (23), choose \( \sqrt{-} \) values of \( \sigma \) from below is to replace of \( \tilde{\chi} \) inequality \([18]\) we obtain the bound

\[
\sum_i \sqrt{e_i} \leq \frac{(1 - \varepsilon)^2 \ell \alpha}{(1 - \varepsilon - \kappa^2 \alpha^2)^{3/2}} \int_B B(x)^2 dx ,
\]

(50)

Finally, we note that since \( \kappa \) is over \( \text{L}^2(\mathbb{R}^3; C^2) \) and not \( \text{L}^2(\mathbb{R}^3) \). As shown in [20], however, the intuition that each negative eigenvalue of \( \tilde{h} \) should be counted only once is correct. Thus, \( \text{Tr}_2[h]_{1/2} \leq \text{Tr}_1[\tilde{h}]_{1/2} \). By the Lieb-Thirring inequality [18] we obtain the bound

\[
\text{Tr}_2[F Y F]^{1/2} = \text{Tr}_2[F Y^{1/2} Y^{1/2} F]^{1/2} = \text{Tr}_2(Y^{1/2} F Y^{1/2} F^{1/2})^{1/2}
\]

(48)

since, quite generally, \( X^* X \) and \( XX^* \) have the same spectrum (up to zero eigenvalues, which are not counted here). Finally, we note that since \( F^2 \leq 1 \), \( Y^{1/2} F Y^{1/2} \leq Y \), and hence \( \text{Tr}_2[F Y F]^{1/2} = \text{Tr}_2(Y^{1/2} F Y^{1/2} F^{1/2})^{1/2} \leq \text{Tr}_2 Y^{1/2} \). Thus, it remains to find an upper bound to \( [h]_{1/2} \) where

\[
h = (1 - \varepsilon - \kappa^2 \alpha^2)(p + \sqrt{\alpha} A(x))^2 + (1 - \varepsilon)\sqrt{\alpha} \chi_{B \sigma} \cdot B(x) .
\]

(49)
with $\ell = 0.060$ \cite{20}.

It is to be emphasized that (50) is an *operator* inequality. That is, the operator in (34), which is part of $H_N^{\text{phys}}$, satisfies

$$H_2 \geq -\frac{(1 - \varepsilon)^2 \ell \alpha}{(1 - \varepsilon - \kappa^2 \alpha^2)^{3/2}} \int_B B(x)^2 \, dx.$$  \hspace{1cm} (51)

The right side of (51) can be controlled by the field energy through inequality (79) — provided $1/8\pi$ is not less than the constant in (50), (51).

### 4.1 Evaluation of Constants

We are now ready to list the conditions on the constants $C_2$ and $\varepsilon$ that have been introduced and to use these to verify the results of Theorem 2.1.

\[
\kappa \geq \max\{64.5, \pi Z\} \hspace{1cm} (52)
\]

Conditions:

\[
(k\alpha)^2 < 1 - \varepsilon \leq 1 \hspace{1cm} (53)
\]

\[
\frac{(1 - \varepsilon)^2 \alpha}{(1 - \varepsilon - \kappa^2 \alpha^2)^{3/2}} \leq \frac{1}{8\pi(0.060)} \hspace{1cm} (54)
\]

The first comes from Theorem 3.1 with $q = 2$. The second is the condition that the kinetic energy term in $H_2$ is positive. The third is the requirement that the field energy $H_f$ dominates the sum of the negative eigenvalues in (50).

Assuming these conditions are satisfied the total energy is then bounded below by the sum of the following four terms (recalling (40) and $\delta^2 = \varepsilon$):

\[
+\sqrt{\varepsilon} \, m N \hspace{1cm} (55)
\]

\[
-\frac{6\sqrt{1 - \varepsilon}}{C_2} \Lambda N \hspace{1cm} (56)
\]

Energy Lower Bounds:

\[
-\frac{\alpha \Lambda}{2C_2} \left(\sqrt{2Z} + 2.3\right)^2 N \hspace{1cm} (57)
\]

\[
-\frac{\Lambda^4}{8\pi^2} \int_B 1 \geq -\frac{4\pi}{3} \frac{\Lambda}{8\pi^2} (3C_2)^3 K = -\frac{9}{2\pi} \Lambda C_2^3 K \hspace{1cm} (58)
\]

The first comes from the $-\delta m$ term in (34). Similarly, the second comes from the $+C_3\Lambda$ term in (34). The third term is the last term in (33) which, in turn, comes from Theorem 3.1. The fourth term is the additive constant in (79) with $w(y) = \chi_B(y)$. The volume of $B$ is bounded by the number of nuclei times the volume of one ball of radius $3L$ around each nucleus.

Obviously we choose

\[
C_2^4 = \frac{N \, 6\sqrt{1 - \varepsilon} + (\alpha/2)(\sqrt{2Z} + 2.3)^2}{\frac{27}{2\pi}}. \hspace{1cm} (59)
\]
The sum of the terms \((\text{55} - \text{58})\) then become our lower bound for the energy
\[
\frac{E}{N} \geq + \sqrt{\varepsilon} m - \frac{18A K}{\pi N} C_2^3 ,
\]
which satisfies stability of the second kind.

To find the largest possible \(Z\) for which stability holds we take \(\alpha = 1/137\) and make the choice \(\varepsilon = 0\). We then find, from (\text{54}), that \(\kappa \alpha \leq 0.97\). Setting \(\kappa = \pi Z\) we find stability up to \(Z = 42\).

The choice \(\varepsilon = 0\) makes the energy in (\text{60}) negative. Recall that if \(Z = 0\) then \(E/N = m\). To make contact with physics we would like the energy to be positive, i.e., only a little less than \(Nm\). To fix ideas, let us consider the case \(\pi Z \leq 64.5\) and \(\alpha = 1/137\). Then \(\kappa = 64.5\), \(\kappa \alpha = 0.471\) and \((\kappa \alpha)^2 = 0.222\). From (\text{54}), we require that (with \(x = 1 - \varepsilon \geq 0\))
\[
x^2 \leq 90.9(x - 0.222)^{3/2},
\]
which means that we can take \(1 - \varepsilon = .229\) or \(\varepsilon = 0.771\).

Now let us consider the case of hydrogen, \(Z = 1\) and \(N = K\) (neutrality). From (\text{59}) we find that \(C_2 = 0.908\). Then (\text{60}) becomes
\[
\frac{E}{N} = 0.866m - 4.29A .
\]
If \(A\) is less than one fifth of the electron’s self-energy, the total energy of arbitrarily many hydrogen atoms is positive. This bound could be significantly improved by more careful attention to our various inequalities.

### A Appendix: A Note About Units

The choice of units in electrodynamics is always confusing, especially when interactions with charged particles are involved.

The interaction of the magnetic vector potential with a charged particle is \(eA(x)\). In cgs units the classical field energy is
\[
H_j^\text{classical} = \frac{1}{8\pi} \int_{\mathbb{R}^3} \left\{ B(x)^2 + E(x)^2 \right\} dx .
\]
With \(B(x) = \text{curl}A(x)\), we use the Coulomb (or radiation gauge) so that \(\text{div}A(x) = 0\) and \(\text{div}E(x) = 0\).

We define \(a_\lambda(k)\) and its complex-conjugate (classically) or adjoint (quantum-mechanically), \(a_\lambda^*(k)\), in terms of the Fourier transform of (the real fields) \(A(x)\) and \(E(x)\) as follows.
\[
A(x) = \frac{\sqrt{\hbar c}}{2\pi} \sum_{\lambda=1}^{2} \int_{\mathbb{R}^3} \frac{\varepsilon_\lambda(k)}{|k|} \left( a_\lambda(k)e^{ik\cdot x} + a_\lambda^*(k)e^{-ik\cdot x} \right) dk \]
\[
E(x) = \frac{i\sqrt{\hbar c}}{2\pi} \sum_{\lambda=1}^{2} \int_{\mathbb{R}^3} \sqrt{|k|} \varepsilon_\lambda(k) \left( a_\lambda(k)e^{ik\cdot x} - a_\lambda^*(k)e^{-ik\cdot x} \right) dk ,
\]
in terms of which

\[ B(x) = \frac{i\sqrt{\hbar/c}}{2\pi} \sum_{\lambda=1}^{2} \int_{\mathbb{R}^3} \frac{k \wedge \varepsilon_{\lambda}(k)}{\sqrt{|k|}} \left( a_{\lambda}(k)e^{ik \cdot x} - a_{\lambda}^*(k)e^{-ik \cdot x} \right) dk . \]  

(66)

The parameter \( \sqrt{\hbar/c}/2\pi \) in (64–66) were chosen purely for convenience later on. The two unit vectors here, \( \varepsilon_{\lambda}(k), \lambda = 1, 2, \) are perpendicular to each other and to \( k \) (which guarantees that \( \text{div} A = 0 \)). They cannot be defined on the whole of \( \mathbb{R}^3 \) as smooth functions of \( k \) (although they can be so defined with the use of ‘charts’), but that will be of no concern to us.

Thus, when (64 – 66) are substituted in (63) we obtain (using Parseval’s theorem and \( \int \exp(ik \cdot x)dx = (2\pi)^3 \delta(k) \) and \( |k|^2 \varepsilon_{\lambda}(k) \cdot \varepsilon_{\lambda}(-k) = -(k \wedge \varepsilon_{\lambda}(k)) \cdot (k \wedge \varepsilon_{\lambda}(-k)) \))

\[ H_f^{\text{classical}} = \frac{1}{2} \hbar c \sum_{\lambda=1}^{2} \int_{\mathbb{R}^3} |k| \left\{ a_{\lambda}^*(k)a_{\lambda}(k) + a_{\lambda}(k)a_{\lambda}^*(k) \right\} dk \]  

(67)

(Although \( a_{\lambda}^*(k)a_{\lambda}(k) = a_{\lambda}(k)a_{\lambda}^*(k) \) for functions, this will not be so when \( a_{\lambda}(k) \) is an operator. The form in (67) is that obtained after the substitution just mentioned.)

To complete the picture, we quantize the fields by making the \( a_{\lambda}(k) \) into operators with the following commutation relations.

\[ [a_{\lambda}(k), a_{\lambda}^*(k')] = \delta_{\lambda, \lambda'} \delta(k - k') \quad \text{and} \quad [a_{\lambda}(k), a_{\lambda'}(k')] = 0 . \]  

(68)

The quantized field energy is obtained from (67, 68) and is given by the Hamiltonian operator

\[ H_f = \hbar c \sum_{\lambda=1}^{2} \int_{\mathbb{R}^3} |k|a_{\lambda}^*(k)a_{\lambda}(k)dk . \]  

(69)

It agrees with (67) up to an additive ‘infinite constant’.

In the rest of this paper we omit \( hc \) since we use units in which \( h = c = 1 \).

B Appendix: Field Energy Bound

In this appendix we prove (79) which relates the localized classical field energy to the quantized field energy. A proof was given in [4]. The small generalization given here is a slightly modified version of that in [13, 14].

Consider a collection of operators (field modes), parametrized by \( y \in \mathbb{R}^3 \), and by \( j \) in some set of integers \( (j \in \{1, 2, 3\} \) in our case of interest) given, formally, by

\[ L_j(y) = \sum_{\lambda=1}^{2} \int_{|k|<\Lambda} \sqrt{|k|} \tilde{\nu}_{\lambda,j}(k)e^{ik \cdot y}a_{\lambda}(k)dk , \]  

(70)
where \( \hat{v}_{\lambda,j} \) is the Fourier transform of some arbitrary complex function \( v_{\lambda,j}(x) \). Our convention for the Fourier transform of a general function \( g(x) \) is

\[
\hat{g}(k) = (2\pi)^{-3/2} \int_{\mathbb{R}^3} g(x) e^{+ik \cdot x} dx \quad \text{and} \quad g(x) = (2\pi)^{-3/2} \int_{\mathbb{R}^3} \hat{g}(k) e^{-ik \cdot x} dk .
\] (71)

The following lemma is elementary. It involves \( v_{\lambda,j}(x) \) and a summable function \( w(x) \), with a norm defined by

\[
\|w\|_v := \sup_{f_\lambda(x)} \frac{\sum_j \int_{\mathbb{R}^3} |\sum \lambda f_\lambda * v_{\lambda,j}(x)|^2 |w(x)| dx}{\sum \lambda \int_{\mathbb{R}^3} |f_\lambda(x)|^2 dx} ,
\] (72)

where * is convolution.

**B.1. LEMMA (Lower bound on field energy).** Assume that \( \|w\|_v \leq 1 \). Then

\[
H_f \geq \sum_j \int_{\mathbb{R}^3} w(y)L_j^*(y)L_j(y)dy .
\] (73)

Moreover, if \( w(y) \geq 0 \), for all \( y \) then

\[
H_f \geq \frac{1}{4} \sum_j \pm \int_{\mathbb{R}^3} w(y)(L_j(y) \pm L_j^*(y))^2 dy - \frac{1}{2} \sum \lambda \sum_{\lambda'} \int_{|k| < \Lambda} |k| |\hat{\omega}_{\lambda,j}(k)|^2 dk \int_{\mathbb{R}^3} w(y)dy ,
\] (74)

for any choice of + or - for each \( j \). (Note that \(-(L - L^*)^2 \geq 0\).)

**Proof.** The difference of the two sides in (73) is a quadratic form of the type

\[
\sum_{\lambda,\lambda'} \int a_{\lambda}(k)Q(k, \lambda : k', \lambda') a_{\lambda'}(k') dkdk'.
\]

In order to establish (73) it is necessary and sufficient to prove that the matrix \( Q(k, \lambda : k', \lambda') \) is positive semidefinite. This is the condition that

\[
\sum_{\lambda=1}^{2} \int_{|k| < \Lambda} |\hat{f}_\lambda(k)|^2 dk \geq (2\pi)^{3/2} \sum_j \sum_{\lambda=1}^{2} \int_{|k|,|k'| < \Lambda} \hat{f}_\lambda(k) \hat{\omega}_{\lambda,j}(k) \hat{f}_\lambda(k') \hat{\omega}_{\lambda,j}(k') \hat{w}(k' - k) dkdk'
\] (75)

for all \( L^2 \) functions \( \hat{f}_\lambda(k) \). Condition (73) is just the condition that \( \|w\|_v \leq 1 \), since \( \hat{f} * \hat{v}(k) = (2\pi)^{3/2} \hat{f}(k) \hat{v}(k) \).

To obtain (74) from (73) we use the three facts that \( w(x) \geq 0 \), that

\[
L_j^*(y)L_j(y) = L_j(y)L_j^*(y) - \sum_{\lambda=1}^{2} \int_{|k| < \Lambda} |k||\hat{\omega}_{\lambda,j}(k)|^2 dk ,
\] (76)

and that, quite generally for operators,

\[
\pm (LL + L^*L^*) \leq L^*L + LL^* .
\] (77)
The following examples are important. First, we define the ultraviolet cutoff fields $A^\Lambda$, $B^\Lambda$, $E^\Lambda$ as in \cite{54,62} except that the $k$ integration is over $|k| \leq \Lambda$ instead of $\mathbb{R}^3$. E.g.,

$$B^\Lambda(x) = \frac{i}{2\pi} \sum_{\lambda=1}^{2} \int_{|k| \leq \Lambda} k \wedge \varepsilon_\lambda(k) \sqrt{|k|} \left( a_\lambda(k)e^{ik \cdot x} - a_\lambda^*(k)e^{-ik \cdot x} \right) dk ,$$

(78)

recalling that $\hbar = c = 1$.

This notation, $A^\Lambda$, $B^\Lambda$, $E^\Lambda$, with the superscript $\Lambda$, will be used in this appendix only.

For the first two examples we define $\hat{v}_{\lambda,j}(k) = ((k \wedge \varepsilon_\lambda(k))_j / (2\pi)^{3/2}|k|$, so that $i(L_j(x) - L_j^*(x)) = B^\Lambda_j(x) / \sqrt{2\pi}$ for $j = 1, 2, 3$.

**Example 1:** Assume that $0 \leq w(y) \leq 1$ for all $y$. Then Lemma [1.1] implies

$$H_f \geq \frac{1}{8\pi} \int_{\mathbb{R}^3} B^\Lambda(x)^2 w(x) dx - \frac{\Lambda^4}{8\pi^2} \int_{\mathbb{R}^3} w(y) dy .$$

(79)

To verify the norm condition (73) we note first that in view of (72) it suffices to assume that $w(y) \equiv 1$. Then, $\hat{w}(k) = (2\pi)^{3/2}\delta(k)$. On the right side of (73) we may use the equality

$$\sum_j \hat{v}_{\lambda,j}(k) \hat{v}_{\lambda',j}(k) = (2\pi)^{-3}\delta_{\lambda,\lambda'}$$

(because $((k \wedge \varepsilon_\lambda(k))/|k|)_j$ are the three components of two orthonormal vectors). Thus, (73) is not only satisfied, it is also an identity with this choice of $\hat{w}$. Finally, (74) is exactly (71) since $\int_{|k| \leq \Lambda} |k| dk = \pi \Lambda^4$.

**Example 2:** Take $w(y) = C\delta(x - y)$, with $x$ some fixed point in $\mathbb{R}^3$ and where $C > 0$ is some constant. Then $\hat{w}(k) = C(2\pi)^{-3/2}\exp(ik \cdot x)$ and $|\hat{w}(k)| = C(2\pi)^{-3/2}$. We take $\hat{v}_{\lambda,j}(k)$ as in Example 1. The right side of condition (72) equals $C\sum_j |\int_{|k| \leq \Lambda} \sum_{\Lambda} \hat{f}_\lambda(k) \hat{v}_{\lambda,j}(k) \exp(ik \cdot x) dk|^2$, and a simple variational argument then says that we should choose $\hat{f}_\lambda(k) = \exp(-ik \cdot x)\hat{v}_\lambda(k) \cdot V$, where $V$ is some fixed vector. By spherical symmetry we can take $\hat{f}_\lambda(k) = \hat{v}_{\lambda,1}(k)$, and (72) becomes

$$1 \geq C \int_{|k| \leq \Lambda} \sum_{\Lambda} |\hat{v}_{\lambda,1}(k)|^2 dk = C \frac{2}{3} \cdot \frac{1}{(2\pi)^3} \cdot \frac{4\pi}{3} \Lambda^3 .$$

(80)

With $C = 9\pi^2 \Lambda^{-3}$, and with

$$\sum_{\Lambda} \sum_j \int_{|k| \leq \Lambda} |k| |\hat{v}_{\lambda,j}(k)|^2 dk \int_{\mathbb{R}^3} w(y) dy = 2 \cdot (2\pi)^{-3} \cdot (4\pi/4) \Lambda^4 C,$$

(74) becomes $H_f \geq \frac{1}{4} \cdot C \cdot (2\pi)^{-1} B^\Lambda(x)^2 - (1/8)\pi^{-2} \cdot \Lambda^4 \cdot C$, or

$$H_f \geq \frac{9\pi}{8} \Lambda^{-3} B^\Lambda(x)^2 - \frac{9}{8} \Lambda$$

(81)

This can also be used \cite{13, 14} with $x$ being the electron coordinate (which is an operator, to be sure, but is one that commutes with the field operators).
Example 3: If we replace \((k \wedge \varepsilon_\lambda(k))_j / |k|\) in \(v_{\lambda,j}(k)\) by \((\varepsilon_\lambda(k))_j\) then everything goes through as before and we obtain (79) and (81) with \(E^\Lambda(x)^2\) in place of \(B^\Lambda(x)^2\).

Example 4: We now take \(\hat{v}_{\lambda,j}(k) = (\varepsilon_\lambda(k))_j (2\pi)^{-3/2} / |k|\), so that \((L_j(x) + L_j^*(x)) = A_j^\Lambda(x) / \sqrt{2\pi}\) for \(j = 1, 2, 3\). The analysis proceeds as in Example 2, except that the normalization condition \((80)\) becomes

\[
1 \geq C \int_{|k| \leq \Lambda} |v_{\lambda,1}(k)|^2 dk = C \frac{2}{3} \cdot \frac{1}{(2\pi)^3} \cdot 4\pi \Lambda \]

which leads to \(C = 3\pi^2 \Lambda^{-1}\). We also have

\[
\sum_\lambda \sum_j \int_{|k| \leq \Lambda} |k| |\hat{v}_{\lambda,j}(k)|^2 dk \int_{\mathbb{R}^3} w(y) dy = 2 \cdot (2\pi)^{-3} \cdot (4\pi/2) \Lambda^2 C ,
\]

so that (84) becomes

\[
H_f \geq \frac{3\pi}{8} \Lambda^{-1} A^\Lambda(x)^2 - \frac{3}{4} \Lambda \]

C Appendix: Spectral properties of the Dirac operators

In this appendix we sketch a proof of the fact that the operators \(D_i(A)\) commute in the sense that all their spectral projections commute. First we start with some remarks concerning the self-adjointness of

\[
D_i(A) = \alpha_i \cdot (-i \nabla_i + \sqrt{\alpha} A(x_i)) + m\beta .
\]

The subscript after \(\alpha\) is a reminder that the matrix acts on the spinor associated with the \(i\)-th particle. It is not easy to characterize the domain for this operator, but it is certainly defined and symmetric on \(\mathcal{H}_N^0 := C^\infty_c(\mathbb{R}^3) \otimes F_{\text{finite}}\), where \(F_{\text{finite}}\) denotes the vectors in Fock space with finitely many photons. This is a dense subset of \(\mathcal{H}_N\). We shall show that \(D_i(A)\) is essentially self-adjoint on \(\mathcal{H}_N^0\). To prove this we resort to a version of Nelson’s commutator theorem given in \(\text{[22]}, \text{Theorem X.37.}\)

Define the operator

\[
\nu = 1 + \sum_{i=1}^{N} (-\Delta_i + m^2) + \Lambda H_f + \Lambda^2 ,
\]

Observe that \(\sum_{i=1}^{N} (-\Delta_i + m^2)\) acts as a multiplication operator on Fourier space and \(H_f\) acts on the \(n\) photon component \(\Phi_{\text{n}}(x_1, \ldots, x_N; \tau_1, \ldots, \tau_N; k_1, \ldots, k_n, \lambda_1, \ldots, \lambda_n)\) by multiplication with \(\sum_{i=1}^{n} \omega(k_i)\). The domain \(\mathcal{H}_N^0\) is a domain of essential self-adjointness for \(\nu\). Certainly, \(\nu \geq 1\) as an operator.
We shall show that there exists a constant $c$ such that for all $\Psi \in \mathcal{H}^0_N$,

$$\|D_i(A)\Psi\| \leq c\|\nu\Psi\|.$$  
(85)

Certainly,

$$\|D_i(A)\Psi\| \leq (\Psi, (-\Delta_i + m^2)\Psi)^{1/2} + (\Psi, A(x_i)^2\Psi)^{1/2}$$  
(86)

and by Example 4 in Appendix B,

$$A(x)^2 \leq \frac{8}{3\pi} \Lambda H_f + \frac{2}{\pi} \Lambda^2.$$  
(87)

The estimate

$$\|D_i(A)\Psi\| \leq c\|\nu\Psi\|$$  
(88)

follows easily from this.

Next, we show that there exists a constant $d$ such that for all $\Psi \in \mathcal{H}^0_N$,

$$\|D_i(A)\Psi\| \leq (\nu\Psi, D_i(A)\Psi) - (D_i(A)\Psi, \nu\Psi) \leq d\|\nu^{1/2}\Psi\|^2.$$  
(89)

Since $-i\alpha \cdot \nabla_i + m\beta$ commutes with $\nu$ when applied to vectors in $\mathcal{H}^0_N$, the above estimate reduces to

$$\|D_i(A)\Psi\| \leq d\|\nu^{1/2}\Psi\|^2,$$  
(90)

where we have dropped the fine structure constant. Since $\nu$ as well as $A(x)$ preserve $\mathcal{H}^0_N$ and are symmetric, we can rewrite the above inequality as

$$\|D_i(A)\Psi\| \leq d\|\nu^{1/2}\Psi\|^2.$$  
(91)

The commutator is the sum of

$$[\alpha \cdot A(x), -\Delta] = i \sum_{i=1}^3 \alpha \cdot (\partial_j A(x) \partial_j + \partial_j \partial_j A(x)) =: X,$$  
(92)

and the operator

$$-i\Lambda \alpha \cdot E(x_i) = [\alpha \cdot A(x_i), \Lambda H_f],$$  
(93)

where $E(x)$ is the electric field. By Schwarz’s inequality,

$$\|D_i(A)\Psi\| \leq (\Psi, (\nabla A)^2\Psi) + (\Psi, -\Delta\Psi),$$  
(94)

and

$$\Lambda \|D_i(A)\Psi\| \leq \Lambda (\|\Psi\|^2 + (\Psi, E(x)^2\Psi)).$$  
(95)
By Example 3 in Appendix B, it follows that as quadratic forms

\[ E(x)^2 \leq \frac{8}{9\pi} \Lambda^3 H_f + \frac{1}{2} \Lambda^4 \]  

(96)

\[ (\nabla A)(x)^2 \leq \frac{8}{9\pi} \Lambda^3 H_f + \frac{1}{2} \Lambda^4 . \]  

(97)

The last inequality does not appear in Appendix B exactly as stated, but it can be derived in precisely the same fashion as the one for the magnetic field displayed there. The estimates (94)-(97) yield (provided \(\Lambda \geq 1\))

\[ |(D_i(A)\Psi, \nu\Psi) - (\nu\Psi, D_i(A)\Psi)| \leq C (\Psi, (\Lambda^3 H_f + \Lambda^4)\Psi) \]  

(98)

\[ \leq C \Lambda^2 (\Psi, \nu\Psi), \]  

(100)

for some constant \(C\), which is the desired estimate.

Thus, the operator \(D_i(A)\) is essentially self-adjoint on \(H_0^N\). This operator, being a sum of two self-adjoint operators, \(U_i := -i\alpha_i \cdot \nabla_i + m\beta\) and \(V_i := \alpha_i \cdot \sqrt{x} A(x_i)\), is naturally defined on \(D(U_i) \cap D(V_i)\) and is symmetric there. Since, \(H_0^N \subset D(U_i) \cap D(V_i)\) we also know that \(D_i(A)\) is essentially self-adjoint on \(D(U_i) \cap D(V_i)\). Thus, by Theorem VIII.31 in [21] the Trotter product formula is valid, i.e.

\[ e^{itD_i(A)} = s - \lim_{m \to \infty} T_i(t/m)^m, \]  

(101)

where

\[ T_i(t/m) := e^{i(t/m)U_i} e^{i(t/m)V_i} . \]  

(102)

Certainly, the operator \(e^{itU_i}\) commutes with \(e^{isU_j}\) and \(e^{isV_j}\), and likewise \(e^{itV_i}\) commutes with \(e^{isU_j}\) and \(e^{isV_j}\) for all \(j \neq i\), and hence \(T_i(t/m)^m\) commutes with \(T_j(s/n)^n\) for all \(s, t, m,\) and \(n\).

We shall use this to show the following

**C.1. LEMMA.** For any two real numbers \(s\) and \(t\) the unitary groups \(e^{itD_i(A)}\) and \(e^{isD_j(A)}\) commute. Moreover, this implies that the spectral projections associated with \(D_i(A)\) and \(D_j(A)\) commute.

**Proof.** For \(\Psi \in H_N\)

\[ \|e^{itD_i(A)}e^{isD_j(A)}\Psi - e^{isD_j(A)}e^{itD_i(A)}\Psi\| \]  

(103)

\[ = \lim_{m \to \infty} \|T_i(t/m)^m e^{isD_j(A)}\Psi - e^{isD_j(A)}T_i(t/m)^m\Psi\| \]  

(104)

\[ = \lim_{m \to \infty} \lim_{n \to \infty} \|T_i(t/m)^m T_j(s/n)^n \Psi - T_j(s/n)^n T_i(t/m)^m\Psi\| = 0 . \]  

(105)

The statement about the spectral projections follows from Theorem VIII.13 in [21].
D Appendix: Projections and symmetries

The difficulty in defining the physical space \( \mathcal{H}_N^{\text{phys}} \) comes from the fact that the projection onto the positive energy subspace acts also on the Fock space. This is in contrast to \([17]\) where no such problem arises. There the action of the permutation group obviously commuted with the projection onto the positive energy subspace. In our more general setting the commutation is still true but an explanation is needed, which we try to give with a minimal amount of formality.

First, consider the one particle space \( \mathcal{H}_1 = L^2(\mathbb{R}^3; \mathbb{C}^4)^\otimes \mathcal{F} \). The Dirac operator, as shown in Appendix C, is a self-adjoint operator on \( \mathcal{H}_1 \) and we denote its projections onto the positive and negative energy subspace by \( P^+ \) and \( P^- \). Note that \( P^+ + P^- \) is the identity. As explained in Section 4, the two projections are unitarily equivalent via

\[
P^- = U^* P^+ U = -UP^+ U
\]  

where, as in (39),

\[
U = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.
\]

The projection onto the positive energy subspace associated with the Dirac operator \( D_i(A) \) is defined in the following fashion. Consider the vector \( \Psi \) as in (12) and fix \( N-1 \) \( x \)'s and \( \tau \)'s, namely all those except \( x_i \) and \( \tau_i \). For almost every such choice (with respect to Lebesgue measure) the vector \( \Psi \) defines a vector in \( \mathcal{H}_1 \). We know how the \( P^\pm \) act on such a vector and the extension to \( \mathcal{H}_N \) we denote by \( P_i^\pm \Psi \). It was shown in Appendix C that these spectral projectors commute with each other.

Other interesting operators on \( \mathcal{H}_N \) are the permutations. A permutation \( \text{Per}_{1,2} \), for example, just exchanges the electron labels 1 and 2. From what has been explained above we have the formula

\[
\text{Per}_{1,2} P_1^\pm = P_2^\pm \text{Per}_{1,2}.
\]  

An immediate consequence is that \( P^\pm := \Pi_{i=1}^N P_i^\pm \) commutes with permutations.

From this it follows that (14) can be rewritten as

\[
\mathcal{H}_N^{\text{phys}} := \mathcal{A} P^+ \mathcal{H}_N = P^+ \mathcal{A} \mathcal{H}_N.
\]

We now address the question whether \( \mathcal{H}_N^{\text{phys}} \) is trivial or not. Denote by \( \mathcal{K} \) the subspace of \( \mathcal{H}_N \) which consists of antisymmetric vectors \( \Psi \) with the property that \( U_j \Psi = i \Psi \) for \( j = 1, \ldots, N \). The operators \( U_j \) are defined in (39). Certainly each \( U_j \) has eigenvalues \( i \) and \( -i \). The space \( \mathcal{K} \) is certainly infinite dimensional. It contains, e.g., determinantal vectors in \( L^2(\mathbb{R}^3; \mathbb{C}^4) \) tensor the photon vacuum.
D.1. LEMMA (\(H_{\text{phys}}^N\) is large). The space \(H_{\text{phys}}^N\) is infinite dimensional.

Proof. We shall show that \(2^{N/2}P^+\) is an isometry from \(K\) into \(H_{\text{phys}}^N\). Let \(I\) be a subset of the integers \(\{1, \ldots, N\}\) and let \(J\) be its complement. Let

\[ P_I = \prod_{i \in I} P_i^- \prod_{j \in J} P_j^+ \]  

(110)

Note that \(\sum P_I = \text{identity}\). Note also that

\[ P_I = \langle - \rangle^{|I|} U_I \prod_{i \in I} P_i^+ U_I \prod_{j \in J} P_j^+ \]  

(111)

which implies that \(\|P_I\Psi\| = \|P^+ \Psi\|\). This shows in particular that

\[ \|P^+ \Psi\|^2 = 2^{-N} \|\Psi\|^2, \]  

(112)

which proves the isometry. \(\square\)

Since we always consider the symmetric operator \(H_{\text{phys}}^N\) in the sense of quadratic forms, it is necessary to construct a domain, \(Q_N\) that is dense in \(H_{\text{phys}}^N\) and on which every term in \(H_{\text{phys}}^N\) has a finite expectation value. Once it is shown that the quadratic form associated with \(H_{\text{phys}}^N\) is bounded below, it is closable and its closure defines a self-adjoint operator, the Friedrich’s extension of \(H_{\text{phys}}^N\).

We first start with a technical lemma that will allow us to approximate vectors in \(H_{\text{phys}}^N\).

D.2. LEMMA. For any \(\hat{f}\) with

\[ C_f := \int_{-\infty}^{\infty} |f(t)| (1 + |t|) dt < \infty \]  

(113)

and

\[ f(D(A)) = \int e^{-itD(A)} \hat{f}(t) dt \]  

(114)

we have that

\[ \|\sqrt{1 + H_f f(D(A))} \Psi\| \leq \max\{\sqrt{1 + 9\Lambda/8}, \sqrt{8/9\pi \Lambda^{3/2}}\} C_f \|\sqrt{1 + H_f} \Psi\|, \]  

(115)

for all \(\Psi \in H_1\).

Proof. We shall assume that \(\Psi\) is normalized. Since

\[ \|\sqrt{1 + H_f f(D(A))} \Psi\| \leq \int |\hat{f}(t)| \|\sqrt{1 + H_f e^{-itD(A)} } \Psi\| dt, \]  

(116)

it suffices to prove the estimate

\[ K(t) := \|\sqrt{1 + H_f e^{-itD(A)} } \Psi\| \leq C(1 + |t|) \|\sqrt{1 + H_f} \Psi\|. \]  

(117)
A simple calculation yields
\[
\frac{d}{dt} K^2(t) = \left( e^{-itD(A)} \Psi, i[H_f, D(A)] e^{-itD(A)} \Psi \right) = - \left( e^{-itD(A)} \Psi, \alpha \cdot E(x) e^{-itD(A)} \Psi \right). \tag{118}
\]
Here \( E(x) \) is the electric field
\[
E(x) = \frac{i}{2\pi} \sum_{i=1}^{2} \int_{|k| \leq \Lambda} dk \varepsilon(k) \sqrt{\omega(k)} \left( e^{ik \cdot x} a_{\lambda}(k) - e^{-ik \cdot x} a_{\lambda}(k) \right). \tag{119}
\]
By Schwarz’s inequality
\[
\frac{d}{dt} K^2(t) \leq \left( e^{-itD(A)} \Psi, E(x)^2 e^{-itD(A)} \Psi \right)^{1/2}. \tag{120}
\]
By Example 3 in Section B
\[
E(x)^2 \leq \frac{8}{9\pi} \Lambda^3 H_f + \frac{1}{\pi} \Lambda^4 \tag{121}
\]
and hence \( K^2(t) \) satisfies the differential inequality
\[
\frac{d}{dt} K^2(t) \leq \left( AK^2(t) + B \right)^{1/2}, \tag{122}
\]
where \( A = \frac{8}{9\pi} \Lambda^3 \) and \( B = \frac{1}{\pi} \Lambda^4 \). This can be readily solved (using \( K(t) \geq 1 \)) to yield the estimate
\[
K(t) \leq (1 + B/A)^{1/2} K(0) + \sqrt{At}. \tag{123}
\]
Thus
\[
\| \sqrt{1 + H_f e^{-itD(A)}} \Psi \| \leq C(1 + |t|) \| \sqrt{1 + H_f} \Psi \|, \tag{124}
\]
where \( C \) is the maximum of \( (1 + B/A)^{1/2} \) and \( \sqrt{A} \).

Next we consider a sequence of functions \( f_n \in C_0^\infty((0, \infty)) \) everywhere less or equal to 1, such that \( f_n \) is identically equals to 1 on the interval \([1/n, n]\). Clearly, as \( n \to \infty \), \( \Pi_{i=1}^N f_n(D_i(A)) \to P^+ \) strongly in \( \mathcal{H}_N \) and hence \( \mathcal{A} \Pi_{i=1}^N f_n(D_i(A)) \to AP^+ \) strongly in \( \mathcal{H}_N \). We denote the range of \( \mathcal{A} \Pi_{i=1}^N f_n(D_i(A)) \) restricted to the subspace of \( \mathcal{H}_N \) consisting of states with \textit{finite field energy expectation} by \( Q_N^n \). Finally we define the domain \( Q_N = \bigcup_{n=1}^\infty Q_N^n \). Together with Lemma D.2 we have the following Corollary.

\textbf{D.3. COROLLARY.} The domain \( Q_N \) is dense in \( \mathcal{H}_N^{\text{phys}} \). Moreover for any vector \( \Psi \in Q_N \) the field energy \( H_f \) has finite expectation value.

\textit{Proof.} Simply note that the functions \( f_n \) have a rapidly decaying Fourier transform for each \( n \). Therefore, by Lemma D.2 the field energy has a finite expectation value for any vector \( \Psi \in Q_N^n \). Note, as before, the antisymmetrization operator \( \mathcal{A} \) commutes with \( \Pi_{i=1}^N f_n(D_i(A)) \). Thus, the field energy has finite expectation value for any \( \Psi \in Q_N \). The density of \( Q_N \) in \( \mathcal{H}_N^{\text{phys}} \) was shown before. \[\square\]
Now we are ready to state the main lemma of this section.

**D.4. LEMMA.** For every $\Psi \in \mathcal{Q}_N$, the Dirac operators $D_i(A)$, the Coulomb potential $V_c$ and the field energy $H_f$ have finite expectation values. Thus, $H_{\text{phys}}^N$ is defined as a quadratic form on $\mathcal{Q}_N$ which is dense in $H_{\text{phys}}^N$.

**Proof.** The operators $D_i(A)^2$ have finite expectation values on $\mathcal{Q}_N$. They are of the form $\hat{T}^P(A) = [(p + \sqrt{\alpha}A(x)) + \sqrt{\alpha} \sigma \cdot B(x)] \otimes I_2$ where $I_2$ is the $2 \times 2$ identity. By (81) the magnetic field is bounded by the field energy and hence has finite expectation value on the domain $\mathcal{Q}_N$. Thus, $(p_i + \sqrt{\alpha}A(x_i))^2 \otimes I_2$ also has finite expectation value on $\mathcal{Q}_N$ for $i = 1, \ldots, N$, and hence the Coulomb potential $V_c$, which is relatively bounded with respect to $\sum_{i=1}^N (p_i + \sqrt{\alpha}A(x_i))^2$ has finite expectation values on $\mathcal{Q}_N$. \qed

### E Appendix: Various forms of instability

In the introduction we talked about the need of using the positive spectral subspace of the Dirac operator $D(A)$, which includes the magnetic vector potential; this led to all sorts of complications in the analysis leading to our main stability Theorem 2.1. In this section we show that various models in which an electron is defined, instead, by the positive spectral subspace of the free Dirac operator $D(0)$ are unstable. In the case of a classical magnetic field such an analysis was carried out in [17] and greatly simplified in [9]. Also, in [9] the stability analysis was carried out for a quantized radiation field without a cutoff. In what follows, we rely mostly on the work in [9]. We also show that the $D(A)$ choice is unstable if $Z\alpha$ or $\alpha$ is too large — as expected.

All the results about stability and instability are summarized in the two tables in Section 1. We remind the reader that instability of the first kind means that the Hamiltonian is unbounded below, while instability of the second kind means that it is bounded below but not by a constant times $N + K$.

#### E.1 Instability without Coulomb potential (free Dirac operator)

Already the free problem, i.e., without Coulomb interactions, shows signs of instability. The Hamiltonian is given by

$$H_N^q = \sum_{j=1}^N D_j(A) + H_f.$$  \hspace{1cm} \text{(125)}

If the field is classical $H_f$ has to be replaced by $(1/8\pi) \int_{\mathbb{R}^3} |B(x)|^2 dx$ as in (1).

We consider first the case where the magnetic vector potential is classical. In particular the Hilbert space $H_{\text{free}}^N$ is the antisymmetric tensor product of $N$ copies of $P^+L^2(\mathbb{R}^3; \mathbb{C}^4)$, i.e., the part of $L^2(\mathbb{R}^3; \mathbb{C}^4)$ that is in the positive spectral subspace of the free Dirac operator. Note that there
is no Fock space in this case. In [9] Theorems 1 and 3 the authors construct, for any $N$, a trial Slater determinant $\psi$ in $H^\text{free}_N$, and a classical field $A$ so that the energy is bounded above by

$$
\left(\psi, H^\text{classical}_N \psi\right) =: \mathcal{E}(\psi, A) \leq aN^{4/3} - \alpha bN^2,
$$

where $a$ and $b$ are constants independent of $N$. The scaling

$$
\psi \to \psi_\mu, \quad \text{and} \quad A \to A^\mu
$$

where

$$
\psi_\mu(x_1, \ldots, x_N; \tau_1, \ldots, \tau_N) = \mu^{3N/2} \psi(\mu x_1, \ldots, \mu x_N; \tau_1, \ldots, \tau_N)
$$

and

$$
A^\mu(x) = \mu A(\mu x)
$$

can be used to get the upper bound

$$
\mathcal{E}(\psi_\mu, A^\mu) \leq \mu \left( AN^{1/3} - \alpha BN^2 \right).
$$

Thus, by choosing $N > a\alpha^{-3/2}/b$, the ground state energy is negative and can be driven to $-\infty$ by letting $\mu \to \infty$, i.e., stability of the first kind is violated.

Using coherent states, it was shown in [9] that this same result extends to the problem with a quantized magnetic vector potential without ultraviolet cutoff.

If $A(x)$ carries an ultraviolet cutoff the $\mu$ scaling argument cannot be applied. The energy, however, is not bounded below by const. $\times N$, as we see from (126), and hence stability of the second kind is also violated — and this no matter how small $\alpha$ may be and whether the magnetic vector potential is quantized or not. The reader might wonder how to construct an $A(x)$ that satisfies the conditions in [9] and, at the same time has an ultraviolet cut off $\Lambda$. Remark 1 on page 1782 of [9] explains that almost any cutoff $A(x)$ will suffice for the purpose.

Notice, that when we use the positive spectral subspace of $D(A)$ instead, the stability of the problem without Coulomb potential is completely trivial, since the Hamiltonian is positive, by definition.

### E.2 Instability with Coulomb potential (free Dirac operator)

Adding the Coulomb potential complicates the analysis owing to the repulsion between the electrons which is present even if there are no nuclei. To some extent this positive energy is balanced by the electron-nuclei attraction if sufficiently many nuclei with sufficiently strong charges are present. It is shown in [17] that if

$$
\sum_{j=1}^{K} Z_j \geq (\text{const.})\alpha^{-3/2} \quad \text{and} \quad \sum_{j=1}^{K} Z_j^2 \geq 2,
$$

where
then the positions of the nuclei can be chosen such that the total Coulomb energy is negative. Thus, if in addition, \( N\alpha^{3/2} \) is sufficiently large, stability of the first kind does not hold for classical magnetic vector potentials as well as for a quantized magnetic vector potential (without ultraviolet cutoff) — no matter how small \( \alpha \) may be.

The situation is more complicated when the field carries an ultraviolet cutoff. The main reason is that the field variable is no longer an active participant for driving the energy towards minus infinity, but it is an active participant in destroying stability of the second kind. We have

**E.1. LEMMA.** Let \( \alpha > 0 \) and assume that (131) holds. Then the system using the projection onto the positive subspace of the free Dirac operator \( D(0) \) is unstable of the second kind, even with an ultraviolet cutoff.

Proof. The lemma follows immediately from (130) and (131) together with the observation in [9] on how to use coherent states to carry these results over to the quantized field case.

**Lemma E.1** is the main reason that the restriction to the positive spectral subspace of \( D(0) \) is inadequate for a model of matter interacting with radiation.

The main result of this paper is the stability of the second kind for the system where the positive subspace of the Dirac operator \( D(A) \) is used. This result holds provided that \( \max_j Z_j \alpha \) and \( \alpha \) is sufficiently small. Our final Lemma E.2 shows that that the two conditions \( \max_j Z_j \alpha \) small and \( \alpha \) small are in fact necessary. It suffices to show this for the case of one electron interacting with \( K \) nuclei, each having charge \( Z \). We have to assume that the electron mass is strictly positive, but we suspect that this assumption is technical and not needed.

**E.2. LEMMA.** Assume that \( Z\alpha > 4/\pi \) and \( m > 0 \). Then the one-electron Hamiltonian

\[
H_1^{\text{phys}} = P^+ \left( D(A) - Z\alpha \sum_{j=1}^{K} \frac{1}{|x - R_j|} + Z^2\alpha \sum_{i<j} \frac{1}{|R_i - R_j|} + H_f \right) P^+ \tag{132}
\]

is unbounded below. Moreover, there is a number \( \alpha_c \) such that for any fixed \( \alpha > \alpha_c \) and any fixed \( Z > 0 \), there exists \( K \) sufficiently large so that this Hamiltonian is unbounded below.

For the classical instead of the quantized \( A \) field see [8, 10, 1, 24, 25].

Proof. The idea is to reduce this problem to the relativistic one without spin and without radiation field. Set \( D_+ = P^+ D(A) \) and \( D_- = -P^- D(A) \), so that \( D(A) = D_+ - D_- \) and \( |D(A)| = D_+ + D_- \). As a trial function we pick \( \psi = g \otimes |0\rangle \), where \( g \) is a spinor that satisfies \( Ug = ig \), recalling the definition of \( U \) from Appendix D (106, 107), and where \( |0\rangle \) is the photon vacuum. A straightforward calculation (which repeatedly uses Schwarz’s inequality and the facts that \( P^- = U P^+ U = -U P^+ U \), and hence \( P^- \psi = -iUP^+\psi \)) shows that

\[
(\psi, H_1^{\text{phys}} \psi) = \left( P^+ \psi, \left[ D_+ - Z\alpha \sum_{j=1}^{K} \frac{1}{|x - R_j|} + Z^2\alpha \sum_{i<j} \frac{1}{|R_i - R_j|} + H_f \right] P^+ \psi \right)
\]
Using the operator monotonicity of the square root it follows that
and from (81) we have that

\[ a \leq \sqrt{b} \leq \sqrt{c} \]

The lemma will be proved by showing that the first term in the last expression can be made as negative as we like while the field energy term is uniformly bounded. Note, as in (9) that

\[ \psi, P^+ H_f P^+ \psi \]

follows easily from Schwarz’s inequality, for any \( D \)

\[ \psi, P^+ H_f P^+ \psi \]

Thus, recalling that \( \psi = g \otimes |0\rangle \)

\[ (\psi, D(A)\psi) \leq \left( g, \sqrt{(1 + \varepsilon)p^2 + \varepsilon \Lambda^2} \right) \]
For any fixed \( \varepsilon, \Lambda \) and \( m \) the terms \( Y_\varepsilon \Lambda^2 + m^2 \) can be scaled away, and this leads to the quadratic form

\[
\left( g, \left[ \sqrt{(1+\varepsilon)p^2} - \frac{Z\alpha}{2} \sum_{j=1}^{K} \frac{1}{|x-R_j|} + Z^2 \alpha \sum_{i<j} \frac{1}{|R_i-R_j|} \right] g \right), \tag{139}
\]

which has been analyzed in detail. Kato [11] showed that instability of the first kind occurs if \( Z\alpha/2\sqrt{1+\varepsilon} > 2/\pi \) which yields our first stated condition for instability. Later on, it was shown in [3] that there exists \( \alpha_c \) so that for \( \alpha > \alpha_c \) and for any \( Z > 0 \) there exists \( K \) so that an instability of the first kind occurs. See also [19], Theorem 3.

Next we address the field energy term and it is here where the assumption about the positive mass comes in. The projection \( P^+ \) can be written as \( P^+ = (1/2)(I + D(A)/|D(A)|) \) and, since \( \psi \) is proportional to the vacuum,

\[
(\psi, P^+ H_f P^+ \psi) = \frac{1}{4} \left( \psi, \frac{D(A)}{|D(A)|} H_f \frac{D(A)}{|D(A)|} \psi \right) = \sum_{\lambda} \int \omega(k) \left\| \left[ a_\lambda(k), \frac{D(A)}{|D(A)|} \right] \psi \right\|^2 dk.
\]

With the help of the expression

\[
\frac{D(A)}{|D(A)|} = \frac{1}{\pi} \int_0^\infty \frac{D(A)}{t + D(A)^2} \frac{1}{\sqrt{t}} \, dt, \tag{140}
\]

and the fact that \((t + D(A)^2)^{-1} = \frac{1}{2}(D(A) - i\sqrt{t})^{-1} + \frac{1}{2}(D(A) + i\sqrt{t})^{-1}, \) the commutator in the last expression of (E.22) can be written as

\[
\left[ a_\lambda(k), \frac{D(A)}{|D(A)|} \right] = - \frac{1}{2\pi} \int_0^\infty \frac{1}{D(A) - i\sqrt{t}} \left[ a_\lambda(k), D(A) \right] \frac{1}{D(A) - i\sqrt{t}} \frac{1}{\sqrt{t}} \, dt
\]

and

\[
\left[ a_\lambda(k), D(A) \right] = \frac{\varepsilon_\lambda(k)}{\sqrt{\omega(k)}} e^{-ik \cdot x} \chi_\lambda(k)
\]

where \( \chi_\lambda(k) \) denotes the characteristic function of the ball in \( k \) space that has radius \( \Lambda \) and is centered at the origin. Hence,

\[
\left\| \left[ a_\lambda(k), \frac{D(A)}{|D(A)|} \right] \psi \right\| \leq \frac{1}{\sqrt{\omega(k)}} \frac{1}{\pi} \int_0^\infty \frac{1}{m^2 + t} \frac{1}{\sqrt{t}} \, dt \| \psi \| \| \chi_\lambda(k) \| = \frac{1}{\sqrt{\omega(k)m}} \| \psi \| \| \chi_\lambda(k) \|, \tag{142}
\]

and the estimate

\[
(\psi, P^+ H_f P^+ \psi) \leq \frac{4\pi \Lambda^3}{3m^2} \| \psi \|^2 \tag{143}
\]

follows.
