Abstract
The Sanfilippo syndrome is an autosomal recessive mucopolysaccharidosis. Homocysteine and B₁₂ status have not been described in this syndrome. A 21-year-old bedridden male with the Sanfilippo syndrome was hospitalized. He was in poor nutritional status according to laboratory and somatometric findings, he had an enlarged liver, moderate aortic valve insufficiency and was under antiepileptic, antipsychotic and anti-cholinergic therapy. The patient had moderate hyperhomocysteinemia (16.9 μmol/L) with co-existing high levels of serum B₁₂ (1,765...
Increased Homocysteine and B₁₂ in a Case with Sanfilippo Syndrome

Detopoulou et al.: Increased Homocysteine and B₁₂ in a Case with Sanfilippo Syndrome

Introduction

The Sanfilippo syndrome is an autosomal recessive mucopolysaccharidosis caused by deficiency in an enzyme responsible for the lysosomal degradation of the glycosaminoglycan heparan sulfate [1]. As a result, heparan sulfate accumulates in various organs and tissues [1]. Although heterogeneity exists, the most common manifestations of the syndrome include developmental delay, aggressive behavior, neurological symptoms, seizures, etc. [1]. To our knowledge, there is no other report of disturbed homocysteine metabolism in the Sanfilippo syndrome.

Case Presentation

A 21-year-old bedridden male with mucopolysaccharidosis type III, also known as Sanfilippo syndrome (subtype B), was hospitalized to place a gastrostomy feeding tube due to frequent aspirations and inability to be adequately fed per os.

The patient was not able to communicate with the doctors but the co-operation with his family was satisfactory. He was under anti-epileptic, antipsychotic and anti-cholinergic treatment. From the patient’s history, it was shown that he had a respiratory infection 3 months ago treated with antibiotics. Moreover, he had increased liver size, borderline enlarged spleen, dolichocolon, and bowel wall thickening, which may imply malabsorption. From the ultrasonography, an aortic valve insufficiency was demonstrated as well as heart wall thickening. The patient was on metronidazole benzoate and ceftriaxone sodium trisesquihydrate treatment due to respiratory infection.

His body weight was 43 kg and his knee height was 51 cm, corresponding to 146 cm height based on the following equation: 64.19 – (0.04 × age) + (2.02 × knee height). His body mass index was 20.1 kg/m² and his mid-arm circumference was 25 cm (<5th percentile).

According to the dietary recall for a typical weekday, the patient’s dietary intake was as follows: energy: 1,490 kcal; protein: 68 g; carbohydrate: 143 g; total fat: 72.6 g; calcium: 1,400 mg; potassium: 2,101 mg; sodium: 1,073 mg; copper: 452 mg; iron: 6.8 mg; magnesium: 188 mg; phosphorus: 1,130 mg; zinc: 6.3 mg; vitamin A: 1,269 RAE; vitamin B₆: 1.4 mg; vitamin B₁₂: 4.5 μg; vitamin C: 26 mg; vitamin D: 9.6 μg; vitamin E: 9.2 mg; folate: 238 μg; thiamin: 1.1 mg; riboflavin: 2.2 mg (analysis with the Food Tracker program

pg/mL). In addition, cystathionine, methionine sulfoxide and certain amino acids were measured. It was hypothesized that a “functional” deficiency of vitamin B₁₂ may be due to problematic transcobalamin-vitamin B₁₂ complex dissociation. Moreover, the patient’s cardiovascular background and/or medical treatment may explain the observed hyperhomocysteinemia. B₁₂ and homocysteine status should be assessed in Sanfilippo patients. This report suggests that checking vitamin B₁₂ and homocysteine status may be useful in the Sanfilippo syndrome.
https://www.supertracker.usda.gov/foodtracker.aspx). The patient had suboptimal intake of energy, dietary fiber, potassium, copper, iron, magnesium, zinc, vitamins C, D, E and folate. However, the week preceding hospitalization, the patient had an even more reduced food and liquid intake.

The patient’s laboratory values upon admission are presented in Table 1. The patient was in poor nutritional status as evidenced by his low mid-arm circumference, low leukocyte count (1.2 ×10⁹/L), hematocrit (32.5%) and hemoglobin (11.0 g/dL). He also had low albumin levels which may be affected by inflammation [2].

The patient had moderate homocysteinemia (16.9 μmol/L) with co-existing high levels of serum B₁₂ (1,765 pg/mL) and normal levels of choline and betaine (shown in Table 2 and Fig. 1). He had high levels of cystathionine, which is produced from homocysteine through transulfuration and high levels of methionine sulfoxide, which is a metabolite of methionine deriving from homocysteine methylation (shown in Fig. 1). Several amino acids were abnormal, i.e., glycine, serine, arginine, threonine and tryptophan.

It is to be noted that the patient has recently been contacted by phone. He is in good health and now is 26 years old. All procedures were in accordance with ethical standards of human experimentation and the mother of the patient gave informed consent for this study. The CARE guidelines for case reports were followed (online suppl. Table 1; for all online suppl. material, see www.karger.com/doi/10.1159/000512215).

Discussion/Conclusion

Homocysteine is synthesized from methionine via demethylation. Then, it is either remethylated to methionine or trans-sulfurated to cysteine [3]. Several nutrients are implicated in these processes such as folate, vitamin B₆, vitamin B₁₂, methionine, choline and betaine [3], most of which were measured in the present work. Increased intake of the aforementioned nutrients has been connected to lower circulating homocysteine [3]. However, in this case increased levels of vitamin B₁₂ co-existed with moderate hyperhomocysteinemia, and increased cystathionine and methionine sulfoxide.

Increased levels of B₁₂ may be documented in several pathological conditions such as liver diseases, cancer, renal insufficiency or excess intake [4]. In the present case, liver enzymes were only borderline elevated with the exception of γ-GT, renal function was normal, while no neoplasm or supplemental use of B₁₂ was reported. Thus, it was hypothesized that the patient has a “functional” deficiency of B₁₂, which may be related to increased homocysteine [4]. Briefly, vitamin B₁₂ circulates as a complex with transcobalamin, which enters the cells by endocytosis and then it is dissociated from transcobalamin in lysosomes [5]. On the grounds of a lysosomal storage disease, such as the Sanfilippo syndrome, we hypothesize that the dissociation of transcobalamin-vitamin B₁₂ complex and “functional deficiency” with low amounts of intracellular bioavailable B₁₂. Moreover, increased levels of serine and threonine have been observed in B₁₂ deficient mice [6], a phenotype also present in this case. An increased degradation of tryptophan to kynurenine has been related to increased homocysteine levels, which
is in line with our findings [7]. Moreover, the route of betaine utilization for homocysteine remethylation [3] seems activated, since its metabolites dimethylglycine, glycine and serine are increased.

Another explanation of the observed hyperhomocysteinemia may lay in the cardiac problems of the patient (cardiac valve disease). Indeed, narrowing of coronary artery luminal and glycosaminoglycan deposition as well as cardiac valve diseases have been observed in patients with Sanfilippo syndrome [8] and homocysteine increases in atherosclerosis [3].

Another point that deserves attention is the role of heparan sulfate, which is elevated in patients with the Sanfilippo syndrome [1]. Homocysteine has been shown to down-regulate heparan sulfate synthesis in vitro [9], but it is unknown how increased heparan sulfate may affect homocysteine and related metabolites. Moreover, heparan sulfate may bind to arginine containing molecules [10], which may explain the observed increased levels of arginine. Last but not least, medical treatment may influence both homocysteine and B_{12} levels [11].

The strength of the present work is the in-depth analysis of several metabolites implicated in homocysteine metabolism. Limitations of the present work lay on its nature; it is a case report and the observed results cannot be generalized.

In summary, we reported a case study of moderate hyperhomocysteinemia with co-existing high levels of serum B_{12} and other micronutrient alterations. A “functional” deficiency of B_{12} was hypothesized, while the patient’s cardiovascular background and/or medical treatment may also explain hyperhomocysteinemia. B_{12} and homocysteine status assessment may be plausible in Sanfilippo patients. This case report serves at sensitizing clinicians in assessing vitamin B_{12} and homocysteine status in Sanfilippo patients.

Acknowledgements

The authors would like to thank Prof. Smaragdi Antonopoulou and Ms. Agathi Ntzouvani for their help in blood transfer and analysis.

Statement of Ethics

The study was conducted ethically in accordance with the World Medical Association Declaration of Helsinki. Written informed consent was obtained from the patient’s mother for publication of this case report.

Conflicts of Interest Statement

The authors have no conflicts of interest to declare.

| Asparagine (μmol/L)                         | 15.7    | 20–130                 |
| Serine (μmol/L)                             | 298     | 95–125                 |
| Glutamine (μmol/L)                          | 523     | 390–700                |
| Glutamic acid (μmol/L)                      | 51      | 20–140                 |
| Phenylalanine (μmol/L)                      | 79      | 26–85                  |
| Ornithine (μmol/L)                          | 90      | 30–90                  |
| Lysine (μmol/L)                             | 134     | 120–290                |
| Histidine (μmol/L)                          | 108     | 70–140²                |
| Tyrosine (μmol/L)                           | 44      | 40–110                 |
| Tryptophan (μmol/L)                         | 35      | 43–89                  |
| Kynurenine (μmol/L)                         | 0.6     | 1.6–2.9                |
